`path-name</member-name>`

The pathname of an r-code library and the name of an r-code file in that library. To specify an r-code file in a library, you must use the double angle brackets as shown. If you specify a relative library pathname, ABL searches the libraries defined in the PROPATH environment variable.

**PERSISTENT [SET proc-handle ]**

Specifies that the external procedure be run and created (instantiated) as a persistent procedure. You can return the handle to the persistent procedure in `proc-handle`, a field, variable, or output parameter defined with the HANDLE data type. If you do not specify `proc-handle`, you can find the procedure handle for this procedure using the FIRST-PROCEDURE and LAST-PROCEDURE attributes of the SESSION system handle. You can use PERSIST as an abbreviation for PERSISTENT.

A persistent procedure creates and maintains its context after it returns to the caller. Other external procedures can access this context through procedure triggers and internal procedures defined in the persistent procedure. Thus, a RUN statement that runs and creates a persistent procedure context is referred to as an instantiating RUN statement.

The order of the PERSISTENT option and the ON SERVER option is interchangeable.

**ON [SERVER] server-handle**

Tells the AVM to run the procedure remotely in the AppServer that the HANDLE variable, `server-handle`, refers to.

With the ASYNCHRONOUS option, `server-handle` causes the called procedure to run asynchronously in the remote session. Control returns immediately to the statement following the RUN statement. Execution of any specified `event-internal-procedure` occurs in the context of an I/O blocking or PROCESS EVENTS statement.

The order of the PERSISTENT option and the ON SERVER option is interchangeable.

**ON [SERVER] session-handle**

Tells the AVM to run the procedure locally in the current ABL session, specified by the value of the SESSION system handle (`session-handle`).

With the ASYNCHRONOUS option, `session-handle` causes the called procedure to run synchronously in the local session, followed immediately by execution of any specified `event-internal-procedure`. Only after execution of the specified
**RUN statement**

`event-internal-procedure` does control return to the statement following the RUN statement.

---

**Note:** This order of execution is different than for a remote procedure call using the `server-handle`.

The order of the PERSISTENT option and the ON SERVER option is interchangeable.

**TRANSACTION DISTINCT**

Tells the AVM not to propagate the calling procedure’s transaction to the AppServer. Although the current version of ABL does not allow transaction propagation, future versions might. Thus, to accommodate this possibility without breaking current code, the current version of ABL allows you to specify this option with `server-handle`.

---

**Note:** It is an error to specify TRANSACTION DISTINCT with a `session-handle`.

**ASYNCHRONOUS [ SET async-request-handle ]**

Specifies that the remote procedure is to be called as an asynchronous request. By default, the remote procedure is called synchronously. The handle to the asynchronous request is returned in `async-request-handle`, which must be a field, variable, or parameter defined with the HANDLE data type. If you specify ASYNCHRONOUS but do not specify SET `async-request-handle`, you can find the handle for the asynchronous request using the LAST-ASYNC-REQUEST attribute of the `server-handle` specified by the ON option. You can also locate the asynchronous request handle by walking the chain between the FIRST-ASYNC-REQUEST and LAST-ASYNC-REQUEST attributes of `server-handle`, searching on the PROCEDURE-NAME attribute of each request handle.

For a Web service operation invoked asynchronously, the handle that is set to the asynchronous request object created for the asynchronous request.

**EVENT-PROCEDURE event-internal-procedure**

Specifies a quoted string or character expression representing the name of an internal procedure that resides within `procedure-context`. When the response from the asynchronous request is received (that is, a PROCEDURE-COMPLETE event occurs), the specified internal procedure is called during subsequent execution of a PROCESS EVENTS or I/O-blocking statement (such as WAIT-FOR). The specified `event-internal-procedure` processes any parameters and errors returned from the asynchronous request. If not specified, no event procedure is executed when the PROCEDURE-COMPLETE event occurs for the asynchronous request.

For information on how the `event-internal-procedure` handles parameters from the asynchronous request, see the `parameter` option. For information on how the `event-internal-procedure` handles errors from the asynchronous request, see the NO-ERROR option.

**IN procedure-context**

A handle to an active procedure that contains the internal procedure specified by `event-internal-procedure`. If not specified, THIS-PROCEDURE is used as the `procedure-context` value.
RUN statement

( parameter [ , parameter ] ... )

Specifies one or more parameters to pass to the called procedure.

For the parameter passing syntax, see the Parameter passing syntax reference entry.

Parameters must be defined in the called procedure. (See the DEFINE PARAMETER statement reference entry.) They must be passed in the same order as they are defined, and they must have compatible data types. The AVM attempts to convert values for data types that do not match. If the AVM cannot convert the value for a mismatched data type, the RUN statement fails with an error condition.

For OUTPUT parameters of an asynchronous remote procedure call only, you can specify parameter-name AS primitive-type-name as a prototype. The parameter-name is an arbitrary place-holder name and primitive-type-name must specify the ABL data type of the corresponding OUTPUT parameter in the asynchronous remote procedure. You can also specify OUTPUT parameters for an asynchronous remote procedure using a local field, variable, or TABLE temp-table-name. However, note that the asynchronous remote procedure does not return any values to OUTPUT or INPUT-OUTPUT parameters on the RUN statement. These parameters are place holders only for values returned by the remote procedure to the specified event-internal-procedure.

Any specified event-internal-procedure can define only INPUT parameters and must define one INPUT parameter for each OUTPUT or INPUT-OUTPUT parameter defined in the asynchronous remote procedure. Each event-internal-procedure INPUT parameter must match the corresponding remote procedure OUTPUT or INPUT-OUTPUT parameter in order and data type. (As with other procedures, the AVM attempts to convert the values for data types that do not match.) The asynchronous remote procedure returns the values of these parameters to the INPUT parameters of the event-internal-procedure after the remote procedure completes execution and the client session processes the associated PROCEDURE-COMPLETE event.

If you are running an internal procedure declared as a Windows dynamic link library (DLL) or UNIX shared library routine, you must match any RETURN parameter specified by a DEFINE PARAMETER statement with a corresponding OUTPUT parameter in the RUN statement. If the internal procedure does not specify the RETURN parameter, do not specify the corresponding OUTPUT parameter in the RUN statement.

For external procedures, the parenthesized list of run-time parameters must precede any compile-time arguments.

argument

A constant, field name, variable name, or expression that you want to pass as a compile-time argument to the external procedure you are running.

When you pass arguments to an external procedure, the AVM converts those arguments to character format. ABL recompiles the called procedure, substitutes arguments, and then runs the procedure. You cannot precompile a procedure to which you pass arguments. (If you use shared variables instead of arguments, the procedure can be precompiled. This yields more efficient code.)

Note: You cannot pass compile-time arguments in a call to an internal procedure.
NO-ERROR (RUN statement specific behavior)

**Note:** See the next entry for a description of general NO-ERROR option behavior. This entry describes special cases for the RUN statement.

Specifies that any ERROR conditions that occur in the attempt to run the procedure are suppressed. This does **not** mean that all errors produced by the called procedure are suppressed; only errors caused by the RUN statement itself. Also, if a specified local or synchronous remote procedure performs a RETURN ERROR, an ERROR is raised for the RUN statement. After the RUN statement completes, you can check the ERROR-STATUS system handle for information on any errors that occurred.

For an asynchronous remote procedure, the result depends on where the errors occur. If the errors occur during the send phase of the asynchronous request, this raises the ERROR condition on the RUN statement in the client (which you can suppress with NO-ERROR). If the errors occur during execution of the remote request and are returned by the AppServer, this results in an implied NO-ERROR on the RUN statement, and you must check the ERROR-STATUS system handle as well as the attributes of the asynchronous request handle (`async-request-handle`) for any error returns in the specified `event-internal-procedure`. If the asynchronous remote procedure returns an unhandled STOP condition, ERROR-STATUS:ERROR and `async-request-handle:ERROR` are both set to FALSE and `async-request-handle:STOP` is set to TRUE.

The RUN statement returns ERROR or STOP for a variety of events depending on the type of procedure that is executed, which includes any of the following:

- All types of procedures
- Local procedures
- All remote procedures
- Synchronous remote procedures
- Asynchronous remote procedures

Table 59 summarizes when the AVM raises ERROR or STOP for each type of procedure.
In addition, under the following conditions, a STOP condition occurs in the context of the I/O-blocking or PROCESS EVENTS statement that invokes any specified `event-internal-procedure`:

<table>
<thead>
<tr>
<th>Procedure type</th>
<th>Condition</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>All procedures</td>
<td>ERROR</td>
<td>The run-time parameters are not compatible.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>Any specified IN <code>proc-handle</code> option is invalid.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>A called internal procedure is not found in the specified external procedure.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>The procedure returns ERROR.</td>
</tr>
<tr>
<td></td>
<td>STOP</td>
<td>The procedure returns an unhandled STOP.</td>
</tr>
<tr>
<td>Local procedures</td>
<td>STOP</td>
<td>The specified procedure is not found.</td>
</tr>
<tr>
<td></td>
<td>STOP</td>
<td>An attempted compile of the procedure failed.</td>
</tr>
<tr>
<td>All remote procedures</td>
<td>ERROR</td>
<td>The specified procedure is not found.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>An attempted compile of the procedure failed.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>The specified ON SERVER <code>server-handle</code> option is invalid.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>The <code>server-handle</code> is not currently connected to some AppServer.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>One of the parameters specified by <code>parameter</code> has a data type of <code>BUFFER</code>.</td>
</tr>
<tr>
<td></td>
<td>ERROR</td>
<td>The PROXY attribute of <code>proc-handle</code> (from the IN <code>proc-handle</code> option) is TRUE and the associated server handle is no longer connected to an AppServer.</td>
</tr>
<tr>
<td>Synchronous remote procedures</td>
<td>ERROR</td>
<td>The ASYNC-REQUEST-COUNT attribute on the <code>server-handle</code> is greater than zero (0).</td>
</tr>
<tr>
<td>Asynchronous remote procedures</td>
<td>ERROR</td>
<td>The REMOTE attribute of <code>procedure-context</code> is set to TRUE.</td>
</tr>
</tbody>
</table>

1 The STOP condition, in this case, is supported for backward compatibility.
• The AVM cannot locate the specified `event-internal-procedure`, for example, because the spelling of `event-internal-procedure` is not identical to the name of the internal procedure definition intended for use as the event procedure.

• The procedure handle that specifies the `procedure-context` to contain the definition of `event-internal-procedure` is not a valid procedure handle.

**NO-ERROR** (general behavior)

---

**Note:** See the previous entry for a description of specific RUN statement NO-ERROR option behavior. This entry describes general NO-ERROR behavior.

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

• Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.

• Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.

• Use ERROR-STATUS:GET-MESSAGE( `message-num` ) to retrieve a particular message, where `message-num` is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

• NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

• A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.
RUN statement

- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

**intern-proc-name**

The name of the (local or remote) internal procedure you want to run. The procedure must be declared in the same procedure file as the RUN statement that calls it unless you specify the IN proc-handle option or use a super procedure. If you do not specify the IN proc-handle option and there is no internal procedure declared by the specified name, the AVM tries to run an external procedure with the specified name. If the internal procedure is remote, you must specify the IN proc-handle option to identify the remote persistent procedure that defines the internal procedure on an AppServer.

**VALUE ( intern-expression )**

An expression that evaluates to the name of the internal procedure you want to run.

**IN proc-handle**

Specifies the handle of the external procedure that declares the internal procedure you want to run. You can specify proc-handle as a field, variable, parameter, or expression that specifies a valid procedure handle or proxy (remote) persistent procedure handle.

**portTypeName**

The name of a Web service PortType as specified in the WSDL file.

**hPortType**

A handle to a procedure object that encapsulates a Web service operation.

**hWebService**

A handle to the server object bound to the Web service.

**operationName**

The name of a Web service operation specified in a WSDL file.

**Examples**

The following procedure displays a simple menu. The user’s selection is stored in the selection variable. The INDEX function returns an integer value that indicates the position of the user’s selection in a string of characters ("12345"). If the value in the selection variable is not in the list of values, the INDEX function returns a 0. The VALIDATE statement ensures that the INDEX function did not return a zero. If it did, VALIDATE displays the message “Not a valid choice.”
In the RUN statement, the INDEX function returns the position of the user's selection in a character string. Suppose you chose option 2 from the menu. That option occupies the second position in the "12345" character string. Therefore, the INDEX function returns the number two (2). Using this number, the RUN statement reads, RUN VALUE(programs[INDEX("12345",selection)]). According to the assignments at the top of the procedure, the value of programs[2] is custedit.p. Now the RUN statement reads, RUN custedit.p, and the r-run.p procedure runs the custedit.p procedure.

The following two external procedures, r-runper.p and r-perpc.p, illustrate the PERSISTENT and IN proc-handle options of the RUN statement. The first procedure, a non-persistent control procedure, sets up a window to run and manage the second procedure as a persistent procedure.

r-run.p

CREATE WINDOW custwin ASSIGN
  TITLE = "Customer Browser"
  SCROLL-BARS = FALSE
  MAX-HEIGHT-CHARS = FRAME CustFrame:HEIGHT-CHARS
  MAX-WIDTH-CHARS = FRAME CustFrame:WIDTH-CHARS.
The control procedure, r-runper.p, runs r-perprc.p each time you choose the Start Customer Query button. Each time it runs, r-perprc.p creates (instantiates) an additional context instance for the persistent procedure, including an additional window to open customer queries. When you choose the Recall All Hidden Queries button from the control window, r-runper.p calls the recall-query internal procedure in each instance of r-perprc.p to redisplay its window. Similarly, when you choose the Exit button, r-runper.p calls the destroy-query internal procedure in each instance of r-perprc.p to delete its context instance; r-runper.p then applies the RETURN event to itself to terminate by completing the WAIT-FOR statement.

The r-perprc.p procedure sets up a customer query that you can re-open three different ways: by name, by balance, or by credit. Each instance of r-perprc.p maintains a separate query for its own local customer buffer. Note that by testing and setting attributes of the THIS-PROCEDURE system handle, r-perprc.p can run either persistently or non-persistently. The basic difference is how the procedure maintains its own context. For example, when running persistently, it defines a trigger on the bCancel button to run its own deletion procedure, destroy-query, to terminate; when running non-persistently, it completes a WAIT-FOR statement with the bCancel button to terminate.

The following example shows how you might implement an asynchronous request. The procedure r-async.p runs persistently from a user-interface trigger, perhaps in response to a menu choice. This procedure, in turn, sends a request to run runReport.p on an AppServer, which provides an inventory report for the specified date.

When r-async.p returns, the user-interface trigger ends and the application returns to its WAIT-FOR state. The user continues to use the application in the normal way while the inventory report runs on the AppServer.

When runReport.p finishes running, a PROCEDURE-COMPLETE event occurs. This event causes the internal procedure reportDone to run automatically within the context of the application’s WAIT-FOR statement. Whatever the user is doing in the application, reportDone displays an alert box indicating whether or not the inventory report completed successfully and the number of lines (numLines) that were output for the report. (The bolded ABL statements indicate the code required to support asynchronous requests to run runReport.p.)
**Notes**

- ABL procedures can be run recursively (a procedure can run itself).

- Progress Version 6 uses time stamps by default to verify that r-code is consistent with the database schema. Some releases of Version 6 provide optional support for CRC codes instead of time stamps. Progress Version 7 and later uses CRC codes by default. If you want to use time stamps instead, specify the Time Stamp (-tstamp) parameter when you connect to a database.

- When a RUN statement raises the STOP condition, the AVM displays the resulting messages on the current output device, even if you specify NO-ERROR. The AVM also writes these messages to the ERROR-STATUS system handle, but sets ERROR-STATUS:ERROR to FALSE.

- You can run an internal procedure that is declared in the current external procedure or in the procedure you specify with the IN proc-handle option. The procedure handle specified by the IN proc-handle option can specify either a valid persistent procedure instance or an external procedure that is active on the procedure call stack. The handle can also specify the current external procedure using the THIS-PROCEDURE system handle. You can check the validity of any procedure handle using the VALID-HANDLE function.

- A called external procedure uses any arguments passed to it from the calling procedure by referring to those arguments as numbers enclosed in braces { }. The first argument is {1}, the next is {2}, etc. Any arguments the called procedure does not use are ignored, and any missing arguments are treated as null values. (Note that the null is a legal value in a WHERE or WITH clause, but its occurrence can cause an error at other points in a called procedure.)
RUN statement

To run an r-code file stored in a library that is not on PROPATH, you must specify the name of the library and the name of the r-code file in the library. Specify these names in the form path-name<<member-name>>, where path-name is the pathname of the library and member-name is the name of the r-code file. For example, if you have an r-code file called appmenu.r in a library whose pathname is /usr/foo/app.pl, you use this command to run it:

RUN /usr/foo/app.pl<<appmenu.r>>.

When you run a procedure and do not specify the PERSISTENT option, the AVM first looks for an internal procedure with the name you specify (this search is not case sensitive). If you specify a procedure in the form path-name<<member-name>>, the AVM looks for an internal procedure with a name in that form. If you specify the PERSISTENT option, or if no internal procedure is found, the AVM searches all the directories and libraries in PROPATH for a usable r-code file of the same name. The AVM also checks to see if the procedure was modified since the last time it was run. If there is a usable r-code file, there is no point in performing the compilation. The RUN statement always uses an existing r-code file before using a session compile version of a procedure.

If you do not want the AVM to check whether the procedure has been modified before using the r-code, use the Quick Request (-q) parameter.

When running an external procedure, it is good practice to specify the name of the source file in the RUN statement. For example, to run r-exit.p you specify the following:

RUN r-exit.p

When you specify a suffix or file extension (such as .p), the AVM first tries replacing that suffix or extension with .r and searches the first directory on your PROPATH for a file with that name. If the r-code file is not found, then it reverts to the original suffix and searches for a source file with that name. If the source file is not found in the first PROPATH directory, then the AVM searches for an r-code file and then a source file in each subsequent directory on your PROPATH until a file is found.

If you specify the .r suffix in the RUN statement, then the AVM searches only for an r-code file in each directory on your PROPATH. If you omit the extension, then the AVM first adds a .r to the name you specify and searches the first directory for an r-code file with that name. If none is found, then the AVM searches for a source file with no suffix or extension.

You cannot run an internal procedure with the PERSISTENT option.

An external procedure called with the PERSISTENT option runs in the same way as a non-persistent procedure with these differences:

- The procedure does not go out of scope when it returns: its context and most of its allocated resources remain active, including input parameters, widgets, variables, buffers, temp-tables, work tables, and triggers created during procedure execution. However, all static dialog boxes, their child widgets, and related triggers created during its execution are destroyed when the procedure returns to the caller. This makes all other windows and dialog boxes in the application available for input.
All buffers passed as parameters to a persistent procedure are treated as local buffers in the persistent context. When the procedure instantiation returns, the output value of the buffer parameter is returned, as usual, to the calling procedure. However, any cursor positioning established during execution of the instantiating RUN statement is lost to the persistent context once the procedure returns; the AVM creates a copy of the buffer parameter and resets its cursors as an initially defined local buffer.

If the procedure obtains any schema share locks (through database access) while executing, these remain in effect after the procedure returns, until the procedure is deleted.

Each time you run a procedure persistently, you create a new instance of its procedure context. All of its data, buffers, and widgets are duplicated and separately managed by the new instantiation until the procedure instance is deleted.

**Note:** If you run an application that creates persistent procedures from an ADE tool (for example, the Procedure Editor or User Interface Builder), that tool removes all instances of persistent procedures still created when the application terminates.

- Transaction scoping is the same whether you run a procedure as persistent or not. Any transaction which begins inside a persistent procedure is scoped to the block that starts the transaction.

- If you run a procedure with the PERSISTENT option and a STOP or QUIT condition or a RETURN ERROR occurs during execution of the procedure, the procedure returns as a non-persistent procedure.

- All shared variables, buffers, temp-tables, ProDataSet objects, work tables, and queries remain in scope as long as a persistent procedure instance remains that accesses them. This is true even if the procedure (persistent or non-persistent) that originally defined the shared data has gone out of scope. Shared data can go out of scope only when no persistent procedure remains that references it.

- You cannot run a procedure with the PERSISTENT option in which you have defined shared streams or shared frame, browse, or menu widgets. Doing so causes the AVM to raise ERROR on the RUN statement.

- You can remove an instance of a persistent procedure using the DELETE PROCEDURE statement. When you delete the procedure instance, its context goes out of scope and all allocated resources are returned to the system. If the procedure has shared dependencies on the call stack, the delete pends until the dependencies are cleared.

- To run a Windows DLL routine as an internal procedure, you must reference the DLL in a PROCEDURE statement and define its parameters in the associated internal procedure block. For more information on accessing DLL routines from ABL, see *OpenEdge Development: Programming Interfaces*.

- To run a UNIX shared library routine as an internal procedure, you must reference the UNIX shared library in a PROCEDURE statement and define its parameters in the associated internal procedure block. You can declare an internal procedure as a routine in a UNIX shared library in the same manner as declaring a DLL routine. The one exception is that the ORDINAL option is not applicable to UNIX and will be ignored. For example:
**RUN statement**

- You can define triggers on procedure handles (procedure triggers). You can apply events to any procedure trigger defined either within a persistent procedure or within any external procedure that is active on the procedure call stack. For example:

```abl
DEFINE VARIABLE phand AS HANDLE NO-UNDO.
RUN persproc.p PERSISTENT SET phand.
. . .
APPLY "RETURN" TO phand.
```

This code fragment assumes that a trigger is defined within `persproc.p` for the `RETURN` event on the `THIS-PROCEDURE` handle.

- If you are using ABL with a DataServer that supports stored procedures, the `RUN` statement has extensions that allow you to execute a stored procedure. For more information, see the entry for the `RUN STORED-PROCEDURE` statement and the appropriate OpenEdge DataServer Guides (OpenEdge Data Management: DataServer for Microsoft SQL Server, OpenEdge Data Management: DataServer for ODBC, and OpenEdge Data Management: DataServer for Oracle).

- If you `RUN` a procedure multiple times within a session, changing the procedure between runs, you must manually recompile the procedure each time. Otherwise, the procedure’s last r-code, which persists for a session, is what is run and the changes do not appear.

- An asynchronous call to a remote procedure (using the `ASYNCHRONOUS` option) causes the `RUN` statement to return control immediately to the following statement in the local context, whether or not the remote procedure has completed execution.

- If an asynchronous call to a remote procedure **does not** raise a `STOP` or `ERROR` condition, the AVM:
  - Increments the `server-handle:ASYNC-REQUEST-COUNT` attribute
  - Increments the `proc-handle:ASYNC-REQUEST-COUNT` attribute, if `PERSISTENT` is specified for a remote external procedure or in `proc-handle` is specified for a remote internal procedure
  - Sets the `async-request-handle:COMPLETE` attribute to `FALSE`, indicating that the request has not completed execution
  - Sets the `async-request-handle:EVENT-PROCEDURE` attribute to the value of `event-internal-procedure`, if `event-internal-procedure` is specified
  - Sets the `async-request-handle:EVENT-PROCEDURE-CONTEXT` attribute to the value of `procedure-context`, if `procedure-context` is specified
  - Submits the request for execution by the AppServer

- The AVM checks the syntax of the `ON SERVER` option at run time. This allows you to use a single `HANDLE` variable that you can set either to a server handle value or the value of `atoi (INPUT in-string, OUTPUT out-int)`.
of the current SESSION handle. Thus, you can use the same RUN statement to execute a procedure remotely in an AppServer or locally depending on application conditions.

- When you specify the ON SERVER option with the SESSION system handle, the RUN statement is functionally similar to not specifying the ON SERVER option at all. That is, the two RUN statements in the following code perform the same function:

```
DEFINE VARIABLE hServer AS HANDLE NO-UNDO.
  hServer = SESSION.
  RUN foo.p.
  RUN foo.p ON SERVER hServer.
```

Allowing the same ON SERVER option to specify either a local session or a remote AppServer session facilitates code generation for applications like the OpenEdge AppBuilder.

With the ASYNCHRONOUS option, using the ON SERVER SESSION option causes the called procedure to run **synchronously** in the local session, followed immediately by execution of any specified `event-internal-procedure`. Only after execution of the specified `event-internal-procedure` does control return to the statement following the RUN statement. This synchronous local execution includes the following differences in error handling from asynchronous execution on an AppServer using ON SERVER `server-handle`:

- If an unhandled ERROR condition occurs during execution of the called local procedure, the error message is displayed on the local output device. This is different from remote execution, where any error message is written to the AppServer log file.

- If the called local procedure causes an ERROR or STOP condition to be raised in the calling procedure (a file not found, mismatched parameters, a compile error, and explicit execution of a RETURN ERROR or STOP statement), the AVM sends the associated message to the standard output device and sets ERROR-STATUS:ERROR appropriately. This is different from remote execution, where the AVM in most cases attaches the associated message to the ERROR-STATUS system handle.

- Also, if the called local procedure causes an ERROR or STOP condition to be raised in the calling procedure (as in the previous note), the AVM raises the condition on the RUN statement, as for a local RUN statement without the ON SERVER option. This is different from remote execution, where the AVM does not raise the condition on the calling RUN statement. You can work around this for the ON SERVER SESSION case by coding each asynchronous RUN statement with the NO-ERROR option and possibly surrounding it with a DO ON STOP UNDO, LEAVE block.

- For more information on AppServers and calling remote procedures synchronously or asynchronously, see *OpenEdge Application Server: Developing AppServer Applications*. 
RUN STORED-PROCEDURE statement

Runs a non-ABL stored procedure or allows you to send SQL to an SQL-based data source using an OpenEdge DataServer.

Syntax

```
RUN STORED-PROCEDURE procedure
    [ integer-field = PROC-HANDLE ]
    [ NO-ERROR ]
    [ ( parameter [ , parameter ] ... ) ]
```

`procedure`

The name of the stored procedure that you want to run or the ABL built-in procedure name, `send-sql-statement`, to send SQL to an SQL-based data source.

`integer-field = PROC-HANDLE`

Assigns a value to the specified integer field or variable (`integer-field`) that uniquely identifies the stored procedure returning results from the non-OpenEdge database or that uniquely identifies the SQL cursor used to retrieve results from an SQL-based, ODBC-compliant data source.

`NO-ERROR`

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the `ERROR-STATUS system handle`. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the `ERROR-STATUS:ERROR` attribute to see if the AVM raised the ERROR condition.
- Check if the `ERROR-STATUS:NUM-MESSAGES` attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the `ERROR-STATUS:ERROR` attribute, but do add messages to the `ERROR-STATUS system handle`. Therefore, this test is the better test for code using

handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.

- Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.
- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.
- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.
- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

**Note:** This option must appear before any run-time parameter list.

**parameter**

A run-time parameter to be passed to the stored procedure. A parameter has the following syntax:

**Syntax**

\[
\begin{array}{c|c|c}
\text{INPUT} & \text{OUTPUT} & \text{INPUT-OUTPUT} \\
\hline
\text{PARAM parameter-name = } & \text{expression} \\
\end{array}
\]

An expression is a constant, field name, variable name, or expression. INPUT is the default. OUTPUT and INPUT-OUTPUT parameters must be record fields or program variables. For ORACLE, OUTPUT and INPUT-OUTPUT work the same way.
If you run send-sql-statement for an SQL-based data source, you must pass a single character expression parameter containing the SQL statement you want the data source to execute.

If you do not specify parameter-name (the name of a keyword parameter defined by the stored procedure), you must supply all of the parameters in correct order. If you do specify parameter-name, you must precede your assignment statement with the keyword PARAM. If you do not supply a required parameter, and no default is specified in the stored procedure, you receive a run-time error.

**Examples**

This procedure runs the ORACLE stored procedure pcust and writes the results of the stored procedure into the ABL-supplied buffer, proc-text-buffer. The same code works for accessing a stored procedure from an ODBC-compliant data source.

```abl
DEFINE VARIABLE intvar AS INTEGER NO-UNDO.
RUN STORED-PROCEDURE pcust intvar = PROC-HANDLE 
  (10, OUTPUT 0, OUTPUT 0) NO-ERROR.
FOR EACH proc-text-buffer WHERE PROC-HANDLE = intvar:
  DISPLAY proc-text-buffer.
END.
IF ERROR-STATUS:ERROR THEN
  MESSAGE "Stored Procedure failed to run".
ELSE
  CLOSE STORED-PROCEDURE pcust WHERE PROC-HANDLE = intvar.
```

This procedure uses the send-sql-statement option of the RUN STORED-PROCEDURE statement to send SQL to ORACLE. It writes the results of the stored procedure into the ABL-supplied buffer, proc-text-buffer. The same code works for sending SQL to an ODBC-compliant data source:

```abl
DEFINE VAR handle1 AS INTEGER.
RUN STORED-PROC send-sql-statement handle1 = PROC-HANDLE 
  ("SELECT name, cust_num FROM customer").
FOR EACH proc-text-buffer WHERE PROC-HANDLE = handle1:
  DISPLAY proc-text.
END.
CLOSE STORED-PROC send-sql-statement WHERE PROC-HANDLE = handle1.
```

This code example shows how to trap errors from the non-OpenEdge RDBMS within a procedure:

```abl
DEFINE VAR h1 AS INTEGER NO-UNDO.
DEFINE VAR jx AS INTEGER NO-UNDO.
RUN STORED-PROC send-sql-statement h1 = PROC-HANDLE NO-ERROR
  ("select count (*) from xxx.customer where name between 'A' and 'Z' ").
IF ERROR STATUS:ERROR THEN
  DO jx = 1 TO ERROR-STATUS:NUM-MESSAGES:
    MESSAGE "error" ERROR-STATUS:GET-NUMBER(jx)
    ERROR-STATUS:GET-MESSAGE(jx).
  END.
CLOSE STORED-PROC send-sql-statement WHERE PROC-HANDLE = h1.
```
Notes

- The RUN STORED-PROCEDURE statement starts a transaction with the same scope as transactions started with the UPDATE statement.

- For more information on using this statement and on using the built-in procedure name, send-sql-statement, see the OpenEdge DataServer Guides (OpenEdge Data Management: DataServer for Microsoft SQL Server, OpenEdge Data Management: DataServer for ODBC, and OpenEdge Data Management: DataServer for Oracle).

See also
CLOSE STORED-PROCEDURE statement, PROC-HANDLE function, PROC-STATUS function

RUN SUPER statement

Runs the super procedure version of the current internal procedure.

The RUN SUPER statement must appear only within an internal procedure, but can appear anywhere within the internal procedure. If the RUN SUPER statement appears outside an internal procedure, the compiler reports an error.

Syntax

```
RUN SUPER [ ( parameter [ , parameter ] ... ) ] [ NO-ERROR ]
```

`parameter`

A parameter of the super procedure. The parameters of the super procedure must have the same signature (number of parameters, and type and mode of each) as the parameters of the current internal procedure. You can, however, adjust a parameter’s value.

For the `parameter` syntax, see the Parameter passing syntax reference entry.

`NO-ERROR`

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

**Note:** Specifying NO-ERROR does not shorten the search in any way.

If you do not specify the NO-ERROR option and the super procedure version of the internal procedure does not exist, the AVM generates an error message:

```
Procedure prog.p name has no SUPER procedure with internal procedure name
```

To check for errors after a statement that uses the NO-ERROR option:
• Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.

• Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.

• Use ERROR-STATUS:GET-MESSAGE(message-num) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

• NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

• A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

• When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

• If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

Example

The following example consists of three procedure files: a main routine, a driver, and a third procedure file that becomes a super procedure of the driver.

The following main routine, procedure file r-pomain.p, runs the driver procedure persistently:
**R-pomain.p**

```plaintext
DEFINE VARIABLE h AS HANDLE NO-UNDO.
DEFINE VARIABLE a AS CHARACTER NO-UNDO.

FUNCTION sample2 RETURNS CHARACTER (INPUT-OUTPUT a AS CHARACTER) IN h.

RUN r-podrvr.p PERSISTENT SET h.
RUN sample1 IN h (INPUT-OUTPUT a).
MESSAGE a VIEW-AS ALERT-BOX.
a = "".
MESSAGE sample2(a) VIEW-AS ALERT-BOX.
```

The following driver, procedure file r-podrvr.p, runs the third procedure file persistently, makes it a super procedure of itself, defines the internal procedure sample1, and defines the user-defined functions sample2, GetPartName, and SetPartName:

**R-podrvr.p**

```plaintext
DEFINE VARIABLE h AS HANDLE. DEFINE VARIABLE localPartName AS CHARACTER.

FUNCTION SetPartName RETURNS INTEGER (INPUT a AS CHARACTER) FORWARD.

/* Add a super procedure */
RUN r-posupr.p PERSISTENT SET h.
THIS-PROCEDURE:ADD-SUPER-PROCEDURE (h).
SetPartName("1998 Calendar").

PROCEDURE sample1:
  DEFINE INPUT-OUTPUT PARAMETER a AS CHARACTER NO-UNDO.

  a = a + "proc: Part name is: ".
  /* Invoke procedure sample1 in the super procedure. */
  RUN SUPER (INPUT-OUTPUT a).
END PROCEDURE.

FUNCTION sample2 RETURNS CHARACTER (INPUT-OUTPUT a AS CHARACTER).
  a = a + "func: Part name is: ".
  /* Invoke function sample2 in the super procedure. */
  SUPER (INPUT-OUTPUT a).
  RETURN a.
END FUNCTION.

FUNCTION GetPartName RETURNS CHARACTER ():
  RETURN localPartName.
END FUNCTION.

FUNCTION SetPartName RETURNS INTEGER (INPUT partname AS CHARACTER):
  localPartName = partname.
END FUNCTION.
```

The following third procedure file, r-posupr.p, defines a new version of the internal procedure sample1 and a new version of the user-defined function sample2:
To start the example, run r-pomain.p from the Procedure Editor.

**Notes**

- To run the super version of a user-defined function, use the SUPER function.
- For the rules that ABL uses to find the super procedure, see the reference entry for the ADD-SUPER-PROCEDURE( ) method.

**See also**

ADD-SUPER-PROCEDURE( ) method, REMOVE-SUPER-PROCEDURE( ) method, SOURCE-PROCEDURE system handle, SUPER function, SUPER-PROCEDURES attribute, TARGET-PROCEDURE system handle
**SAVE CACHE statement**

Saves the schema cache of a database to an operating system file. Subsequent sessions can then share the same cache by using the Schema Cache File (\-cache) parameter.

**Syntax**

```
SAVE CACHE
  { CURRENT | COMPLETE }
  { database-name | VALUE ( char-exp ) }
TO
  { pathname | VALUE ( char-exp ) }
  [ NO-ERROR ]
```

**CURRENT**

Specifies that only the portion of the schema cache that applies to referenced tables is saved to the file. By using this option you can tailor a small schema cache file for an application that does not use all the tables in the database.

**COMPLETE**

Specifies that the complete schema cache for the database is saved to the file. If you use this option, the client process builds a complete schema cache in memory including template records and all trigger information for every table in the database.

**database-name**

Specifies the literal logical name of a currently connected OpenEdge database.

**pathname**

Specifies the literal pathname of an operating system file to hold the schema cache.

**VALUE (char-exp)**

Returns the corresponding literal database name or pathname specified by the character expression in `char-exp`.

**NO-ERROR**

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.

- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block
**SAVE CACHE statement**

**without** a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block **with** a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.

- Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- **NO-ERROR** does not suppress errors that raise the STOP or QUIT condition.

- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

**Example**

This procedure saves the complete schema cache for each database that you specify in the current working directory, and displays any error messages associated with connecting or saving the cache:
Notes

• The schema cache is saved to the file in a binary format that is portable across machines.

• For information on using an existing schema cache file, see OpenEdge Data Management: Database Administration. For information on the Schema Cache File (-cache) startup parameter, see OpenEdge Deployment: Startup Command and Parameter Reference.

• Any schema changes to the database make the saved cache invalid. If the schema cache file is invalid when the AVM tries to access it, the AVM displays a warning message, ignores the file, and reads the required schema cache from the database.

• To set up your database environment to use the CURRENT option, you only have to connect to the database and read from the tables that compose the schema you want to save. This is sufficient for the SAVE CACHE statement to save all parts of each table in the schema, including template records and trigger information. If you want to save a different subschema of the database, you must disconnect and then reconnect to the database before reading the tables for that subschema.

• For a DataServer, the AVM saves the schema cache for the entire schema holder database. You cannot save the schema cache for a non-OpenEdge database separately. For more information on schema cache files for DataServers, see the OpenEdge DataServer Guides (OpenEdge Data Management: DataServer for Microsoft SQL Server, OpenEdge Data Management: DataServer for ODBC, and OpenEdge Data Management: DataServer for Oracle).

See also CONNECT statement, ERROR-STATUS system handle
SCREEN-LINES function

Returns, as an INTEGER value, the number of lines you can use to display frames. This value
omits the space used by the message area and status area.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```
SCREEN-LINES
```

**Example**

Here, a different number of customer records is displayed depending on the number returned by
the SCREEN-LINES function:

```
r-scrln.p
```

```
DEFINE VARIABLE nbrdown AS INTEGER NO-UNDO.
nbrdown = IF SCREEN-LINES > 21 THEN 7 ELSE 6.
FOR EACH Customer NO-LOCK WITH nbrdown DOWN:
END.
```

SCROLL statement

Moves data up or down in a frame with multiple rows. Use the SCROLL statement to scroll data
up or down when you add or delete a line in a frame.

This statement is supported only for backward compatibility.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```
SCROLL [ FROM-CURRENT ] [ UP | DOWN ] { [ frame-phrase ] }
```

FROM-CURRENT

Scrolls UP or DOWN rows of data at or below the current cursor location. When scrolling
UP, a new line opens at the bottom of the frame. When scrolling DOWN, a new line opens
at the current cursor location. For example:
If you do not use the FROM-CURRENT option, then the entire frame scrolls up or down and the newly opened line appears at the top or bottom of a frame, respectively. FROM-CURRENT limits scrolling from the current cursor position to the bottom of the frame.

UP

Scrolls rows of data up and off the frame and opens a line at the bottom of the frame. UP is the default. For example:

DOWN

Scrolls rows of data down and off the frame and opens a line at the top of the frame. For example, the Original Frame in the next example shows four rows of data. The highlighted bar is the current cursor position and the frame is a scrolling frame. On the right, the SCROLL FROM-CURRENT DOWN statement opens a line in the frame at the current cursor location and moves the other rows down and off the frame. For example:
In the next example, the SCROLL DOWN statement opens a line at the top of the frame and moves the other rows of data down and off the frame:

```
<table>
<thead>
<tr>
<th>Item-num</th>
<th>Item-num</th>
</tr>
</thead>
<tbody>
<tr>
<td>00001</td>
<td>00001</td>
</tr>
<tr>
<td>00002</td>
<td>00002</td>
</tr>
<tr>
<td>00003</td>
<td>00003</td>
</tr>
<tr>
<td>00004</td>
<td></td>
</tr>
</tbody>
</table>
```

In the next example, the SCROLL DOWN statement opens a line at the top of the frame and moves the other rows of data down and off the frame:

```
<table>
<thead>
<tr>
<th>Item-num</th>
<th>Item-num</th>
</tr>
</thead>
<tbody>
<tr>
<td>00001</td>
<td>00001</td>
</tr>
<tr>
<td>00002</td>
<td>00002</td>
</tr>
<tr>
<td>00003</td>
<td>00003</td>
</tr>
</tbody>
</table>
```

**frame-phrase**

Specifies the overall layout and processing properties of a frame. For more information on **frame-phrase**, see the Frame phrase reference entry.

**Examples**

This procedure displays Customer information and lets you try each scrolling option from a menu of selections:
The next procedure creates a scrolling frame of five iterations. The frame displays the CustNum, Name, Address, and City for each Customer. The status default message displays “Enter C to create, D to delete” as long as the procedure is running. You use arrow keys to move the highlighted cursor bar through the database, and to add or delete Customers from the database. The CHOOSE statement lets you easily create this style menu. See the CHOOSE statement reference entry for more information.
DEFINE VARIABLE counter AS INTEGER NO-UNDO.
DEFINE VARIABLE oldchoice AS CHARACTER NO-UNDO.

  WITH FRAME cust-frame SCROLL 1 5 DOWN ATTR-SPACE.

FIND FIRST Customer NO-LOCK.

REPEAT counter = 1 TO 5:
  WITH FRAME cust-frame.
  DOWN WITH FRAME cust-frame.
  FIND NEXT Customer NO-LOCK NO-ERROR.
  IF NOT AVAILABLE customer THEN LEAVE.
END.

UP 5 WITH FRAME cust-frame.
oldchoice = "".

REPEAT:
  STATUS DEFAULT "Enter C to create, D to delete".
  CHOOSE ROW Customer.CustNum NO-ERROR GO-ON (CURSOR-RIGHT)
    WITH FRAME cust-frame.

  /* After choice */
  IF FRAME-VALUE = "" THEN NEXT.

  /* Force user to press END or move cursor to valid line */
  IF FRAME-VALUE <> oldchoice THEN DO:
    oldchoice = FRAME-VALUE.
    FIND Customer WHERE Customer.CustNum = INTEGER(FRAME-VALUE).
  END.

  /* React to moving cursor off the screen */
  IF LASTKEY = KEYCODE("CURSOR-DOWN") THEN DO:
    FIND FIRST Customer NO-LOCK.
    DOWN WITH FRAME cust-frame.
    WITH FRAME cust-frame.
    NEXT.
  END. /* KEYCODE("CURSOR-DOWN") */

  IF LASTKEY = KEYCODE("CURSOR-UP") THEN DO:
    FIND PREV Customer NO-LOCK NO-ERROR.
    IF NOT AVAILABLE Customer THEN
      FIND LAST Customer NO-LOCK.
      UP WITH FRAME cust-frame.
      WITH FRAME cust-frame.
      NEXT.
  END. /* KEYCODE("CURSOR-UP") */
The SCROLL statement controls the scrolling action in the frame when you create and delete customers. To add a customer to the database, type **C**. Create opens a line in the frame and the SCROLL statement moves data below the line down. Then you type the new customer information into the frame. Type **D** to delete a Customer from the database. When you delete a Customer, all rows below the deleted Customer row move up one row.

You can perform the same function with fewer statements if you do not use the SCROLL statement. You can substitute the `r-chose1.p` procedure segment with the `r-chose2.p` to perform the delete function.

```plaintext
/* CHOOSE selected a valid key. Check which key. */
IF LASTKEY = KEYCODE("c") THEN DO: /* Open a space in the frame. */
   SCROLL FROM-CURRENT DOWN WITH FRAME cust-frame.
   CREATE Customer.
      WITH FRAME cust-frame.
   oldchoice = INPUT Customer.CustNum.
   NEXT.
END. /* KEYCODE("c") */

IF LASTKEY = KEYCODE("d") THEN DO: /* Delete a customer. */
   DELETE Customer.
   FIND NEXT Customer NO-ERROR.
   /* Move to correct position in database. */
   IF NOT AVAILABLE Customer THEN DO:
      FIND FIRST Customer NO-ERROR.
      IF NOT AVAILABLE Customer THEN DO:
         CLEAR FRAME cust-frame.
         UP WITH FRAME cust-frame.
         NEXT.
      END.
   END.

   /* If last screen line deleted */
   IF FRAME-LINE(cust-frame) = FRAME-DOWN(cust-frame) THEN DO:/*
         WITH FRAME cust-frame.
      NEXT.
   END.

   SCROLL FROM-CURRENT WITH FRAME cust-frame.
   REPEAT counter = 1 TO 100
      WHILE FRAME-LINE(cust-frame) < FRAME-DOWN(cust-frame):
         FIND NEXT Customer NO-ERROR.
         IF NOT AVAILABLE Customer THEN DO:
            FIND FIRST Customer NO-ERROR.
            IF NOT AVAILABLE Customer THEN LEAVE.
         END.
         DOWN WITH FRAME cust-frame.
         IF INPUT Customer.CustNum = "" THEN
            DISPLAY Customer.CustNum Customer.Name Customer.Address
               Customer.City WITH FRAME cust-frame.
         END.
      END.
      UP counter - 1 WITH FRAME cust-frame.
      oldchoice = INPUT Customer.CustNum.
   END. /* KEYCODE("d") */
END. /* REPEAT */

STATUS DEFAULT.
```
r-chose2.p

```plaintext
. . .
IF LASTKEY = KEYCODE("d") THEN DO: /* Delete a customer. */
   DELETE Customer.
   REPEAT counter = 1 TO 100
   WHILE FRAME-LINE(cust-frame) <= FRAME-DOWN(cust-frame).
   FIND NEXT Customer NO-ERROR.
   IF AVAILABLE Customer THEN
         WITH FRAME cust-frame.
      ELSE CLEAR FRAME cust-frame.
      DOWN WITH FRAME cust-frame.
   END.
   UP counter - 1 WITH FRAME cust-frame.
   oldchoice = INPUT Customer.CustNum.
END. /* KEYCODE("d") */
. . .
```

You can see the entire `r-chose2.p` procedure on-line. This example only shows the portion that is different from the `r-chose1.p` procedure.

The `r-cuhelp.p` procedure provides help for the CustNum field when a user presses HELP. It displays five Customer names and numbers. The user can press (UP-ARROW), (DOWN-ARROW), to scroll down, or (RETURN) to exit.
SDBNAME function

Accepts an integer expression or a character expression as a parameter. If the parameter resolves to a currently connected non-OpenEdge database then the SDBNAME function returns the logical name of the schema holder database containing the non-OpenEdge schema. If the parameter resolves to a currently connected OpenEdge database, the SDBNAME function returns the logical name of this database.

Syntax

\[
\text{SDBNAME} \ (\{ \text{integer-expression} \mid \text{logical-name} \mid \text{alias} \})
\]

\text{integer-expression}

If the parameter supplied to SDBNAME is an integer expression, and there are, for example, three connected databases, then SDBNAME(1), SDBNAME(2), and

---

See also

CHOOSE statement, Frame phrase
SDBNAME(3) return the logical names of their respective schema holder databases. Also, if there are three connected databases, SDBNAME(4), SDBNAME(5), etc., return the Unknown value (?) .

logical-name or alias

These forms of the SDBNAME function require a quoted character string or a character expression as a parameter. If the parameter is the logical name of a connected database or an alias of a connected database, then the logical name of the schema holder database is returned according to the rule. Otherwise, SDBNAME returns the Unknown value (?) .

Example

This procedure displays schema holder databases, if applicable, for all connected databases:

```
r-sdbnm.p

DEFINE VARIABLE ix AS INTEGER NO-UNDO.
REPEAT ix = 1 TO NUM-DBS:
   DISPLAY SDBNAME(ix) SDBNAME(ix) = LDBNAME(ix)
   FORMAT "SCHEMA-HOLDER/SUB-SCHEMA        "
   COLUMN-LABEL " DataServer!Classification".
END.
```

See also

ALIAS function, CONNECT statement, CONNECTED function, CREATE ALIAS statement, CREATE CALL statement, DATASERVERS function, DBCODEPAGE function, DBCOLLATION function, DBRESTRICTIONS function, DBTYPE function, DBVERSION function, DELETE ALIAS statement, DISCONNECT statement, FRAME-DB function, LDBNAME function, NUM-DBS function, PDBNAME function

SEARCH function

Searches the directories and libraries defined in the PROPATH environment variable for a file. The SEARCH function returns the full pathname of the file unless it is found in your current working directory. If SEARCH does not find the file, it returns the Unknown value (?) .

Syntax

```
SEARCH ( opsyst-file )
```

opsyst-file

A character expression whose value is the name of the file you want to find. The name can include a complete or partial directory path. If opsyst-file is a constant string, you must enclose it in quotation marks (" "). The value of opsyst-file must be no more than 255 characters long.

Example

In this procedure, the SEARCH function returns the fully qualified pathname of the filename entered if it is not in the current working directory. If SEARCH cannot find the file, it returns the Unknown value (?) . The procedure displays the fully qualified pathname or a message indicating that the file could not be found.
The SEARCH function is double-byte enabled. You can specify a filename with the opsys-file argument that contains double-byte characters.

Use the SEARCH function to ensure that procedures that get input from external data files are independent of specific directory paths. The files must be in one of the directories or libraries defined in the PROPATH environment variable.

Typically, the PROPATH includes a nil entry representing the current working directory. If the SEARCH function finds the file when searching this entry, it returns only the simple name of the file rather than the full pathname. If the PROPATH does not include a nil entry or another entry that specifies the current working directory, the SEARCH function does not search the current working directory.

If you provide a fully qualified pathname, SEARCH checks if the file exists. In this case, SEARCH does not search directories on the PROPATH.

When you search for a file that is in a library, SEARCH returns the file’s pathname in the form path-name<<member-name>>, where path-name is the pathname of the library and member-name is the name of the file. The double angle brackets indicate that the file is a member of a library. For example, in the path /usr/apps.pl<<proc1.r>>, proc1.r is the name of the file in the library apps.pl.

The LIBRARY function and MEMBER function use the special syntax to return, respectively, the library name and member-name of the file in the library.

If an application repeatedly runs a procedure, you can improve performance by using the SEARCH function once to build a full pathname for that procedure. Use this value in the RUN statement to avoid repeated searches of the PROPATH.

In Windows, you can specify URL pathnames on the PROPATH. If the file is found in a directory specified by a URL, SEARCH returns the full URL pathname of the file which includes the filename appended to the URL PROPATH entry. If you provide a fully-qualified URL, SEARCH checks if the file exists. In this case, SEARCH does not search URLs on the PROPATH. Valid URL protocols include HTTP and HTTPS.

Note: URL pathnames cannot contain the percent symbol (%). If an error exists in a URL specified on the PROPATH, the SEARCH function continues searching with the next PROPATH entry.
• If you specify URL pathnames on the **PROPATH** and your application repeatedly uses the **LOAD-ICON( )**, **LOAD-SMALL-ICON( )**, **LOAD-IMAGE( )**, **LOAD-IMAGE-DOWN( )**, **LOAD-IMAGE-UP( )**, **LOAD-IMAGE-INSENSITIVE( )**, or **LOAD-MOUSE-POINTER( )** methods with a URL pathname, you can improve performance by using the **SEARCH** function once to determine the full URL pathname to the directory containing the image files. Use this value with the load methods to avoid repeated searches of the **PROPATH**.

**SEEK function**

Returns the offset of the file pointer in a text file as an INT64 value. You define a procedure variable to hold the offset value and later position the file to that offset.

**Syntax**

```
SEEK ( { INPUT | OUTPUT | name | STREAM-HANDLE handle } )
```

**INPUT**

If you specify **INPUT**, the **SEEK** function returns the current position of the file pointer in the unnamed input stream.

**OUTPUT**

If you specify **OUTPUT**, the **SEEK** function returns the current position of the file pointer in the unnamed output stream.

**name**

If you specify **SEEK( name)**, the **SEEK** function returns the current position of the file pointer in the named input or output stream. The stream must be associated with an open file, or **SEEK** returns the Unknown value (??).

**STREAM-HANDLE handle**

If you specify the handle to a stream, the **SEEK** function returns the current position of the file pointer in the stream. If **handle** it is not a valid handle to a stream, the AVM generates a run-time error.

**Example**

This procedure shows how you can use the **SEEK** function to access data in a text file. Using **SEEK** this way allows you to index into a non-indexed file.
SEEK statement

Positions the file pointer to a user-defined offset in a text file. This statement does not require you to close and reopen the file.

Syntax

```
SEEK
{ INPUT | OUTPUT | STREAM stream | STREAM-HANDLE handle }
TO { expression | END }
```

INPUT

If you specify INPUT, the SEEK statement positions the file pointer in the unnamed input stream.

Notes

- The first byte in a file is byte 0.
- You cannot use the SEEK function with the INPUT THROUGH statement, the INPUT-OUTPUT THROUGH statement, or the OUTPUT THROUGH statement. When used with one of these statements, the SEEK function returns the Unknown value (?).
- After you assign the value of the SEEK function to a procedure variable, you can use that value to reposition the file in the event of an error.
- For more information on streams, see the chapter on alternate I/O sources in OpenEdge Development: Programming Interfaces.

See also

DEFINE STREAM statement, INPUT FROM statement, OUTPUT TO statement, SEEK statement, Stream object handle
OUTPUT

If you specify OUTPUT, the SEEK statement positions the file pointer in the unnamed output stream.

STREAM stream

If you specify STREAM stream, the SEEK statement positions the file pointer in the named input or output stream. If you do not name a stream, the AVM uses the unnamed stream.

STREAM-HANDLE handle

If you specify the handle to a stream, the SEEK statement returns the current position of the file pointer in the stream. If handle is not a valid handle to a stream, the AVM generates a run-time error.

TO expression

An expression whose value is INT64 that indicates the byte location to position the file pointer. If expression equals 0, the file pointer is positioned to the first byte in the file. If you want to position the pointer to the last byte in the file, but you do not know the offset, use END.

END

Positions the pointer to the last byte in the file.

Example

Since text file formats differ on each machine, the SEEK function does not necessarily return a number that is meaningful to anyone, but it is meaningful to the SEEK statement. With the exception of SEEK to 0 or SEEK TO END, any address used in the SEEK statement is only guaranteed to behave consistently if the address was previously derived from the SEEK function. Therefore, an expression such as SEEK TO SEEK (INPUT) -n might work differently on different operating systems. Record delimiters must be new-lines on UNIX, and carriage-return/linefeed pairs on all others.

r-seek.p

```/* This procedure seeks to the end-of-file, collects the seek address, and writes a record. The record is subsequently retrieved using the SEEK statement on the stashed seek address. */

DEFINE VARIABLE savepos AS INT64 NO-UNDO.
DEFINE VARIABLE c AS CHARACTER NO-UNDO FORMAT "x(20)".

OUTPUT TO seek.out APPEND NO-ECHO.
savepos = SEEK(OUTPUT).
PUT UNFORMATTED "abcdefg" SKIP.
OUTPUT CLOSE.

INPUT FROM seek.out NO-ECHO.
SEEK INPUT TO savepos.
SET c.
DISPLAY c.
INPUT CLOSE.```

Notes

- The SEEK statement does not work with named streams identified in the INPUT-THROUGH, OUTPUT-THROUGH, or INPUT-OUTPUT-THROUGH statements.
An expression such as SEEK TO SEEK (INPUT) -n might work differently on different operating systems.

For more information on streams, see the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces*.

DEFINE STREAM statement, INPUT FROM statement, OUTPUT TO statement, SEEK function, Stream object handle

---

**SELECTION-LIST phrase**

Describes the selection-list representation of a field or variable. A selection-list is a scrollable list of values. The SELECTION-LIST phrase is an option of the VIEW-AS phrase.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```plaintext
SELECTION-LIST
  [ SINGLE | MULTIPLE ]
  [ NO-DRAG ]
  { LIST-ITEMS item-list | LIST-ITEM-PAIRS item-pair-list }
  [ SCROLLBAR-HORIZONTAL ]
  [ SCROLLBAR-VERTICAL ]
  { size-phrase
    | { INNER-CHARS cols INNER-LINES rows }
  }
  [ SORT ]
  [ TOOLTIP tooltip ]
```

**SINGLE**

Specifies that on input the user can select only a single item from the list. This is the default. The value of the selection-list is set to the character-string item the user selects.

**MULTIPLE**

Specifies that on input the user can select one or more items from the item list. The value of the selection-list is set to a comma-separated list of character-string items that the user selects.

**NO-DRAG**

Specifies that the user cannot select items by simultaneously holding down the mouse select button and dragging the mouse through the list.

If you specify NO-DRAG then the DRAG-ENABLED attribute is set to FALSE. You can set the DRAG-ENABLED attribute only before the selection-list is realized. The default is TRUE.

In Windows, DRAG-ENABLED is always TRUE and the NO-DRAG option is ignored.
LIST-ITEMS  
\[item-list\]
Specifies the items to appear in the list. \[item-list\] represents a comma-separated list of character-string constants.

LIST-ITEM-PAIRS  
\[item-pair-list\]
Specifies a list of label-value pairs. Each pair represents a label and value of the associated field or variable. When the selection-list appears, it displays each pair’s label. Then, if the user selects a label, the AVM assigns the corresponding value to the field or variable. The syntax for \[item-pair-list\] is as follows:

**Syntax**

\[
label, value [ , label, value ] ... \\
\]

*label*

A character string representing the label of the field or variable.

*value*

A valid value for the field or variable.

SCROLLBAR-VERTICAL

Specifies that a scroll bar is displayed along side the selection-list. The user can browse through a long selection-list by manipulating the slider.

SCROLLBAR-HORIZONTAL

Specifies that a scroll bar is displayed along the bottom of the selection-list. The user can view long list items by manipulating the slider.

\[size-phrase\]

Specifies the outside dimensions of the selection-list widget. Following is the syntax for the \[size-phrase\]:

**Syntax**

\[
\{ SIZE | SIZE-CHARS | SIZE-PIXELS \} width BY height \\
\]

For more information, see the SIZE phrase reference entry.

INNER-CHARS  \[cols\] INNER-LINES  \[rows\]

Specifies the number of character positions visible in each line of the selection-list and the number of lines visible in the selection-list. Both \[cols\] and \[rows\] must be integer constants.

Note that the values you supply for INNER-CHARS and INNER-LINES specify only the size of the list, not the overall size of the selection-list widget. The overall size is determined by the size of the list plus the sizes of the margin and border heights and widths.
SORT

Specifies that list items are sorted prior to display.

TOOLTIP tooltip

Allows you to define a help text message for a text field or text variable. The AVM automatically displays this text when the user pauses the mouse button over a text field or text variable for which a tooltip is defined.

You can add or change the TOOLTIP option at any time. If TOOLTIP is set to '"' or the Unknown value (?), then the tooltip is removed. No tooltip is the default. The TOOLTIP option is supported in Windows only.

Example

The r-select.p procedure prompts the user for a directory name and then populates a selection-list with the contents of the specified directory. After the user selects an item from the selection-list, the procedure echoes back the selection.

The procedure uses the INPUT FROM statement to read the contents of the user-specified directory and creates a comma-separated list of all the file and directory names in the directory. It then assigns the comma-separated list to the LIST-ITEMS attribute of the selection-list. Because an assignment to an attribute depends on the widget being located in a frame, the DEFINE FRAME statement is used to locate the selection-list.

r-select.p

```
DEFINE VARIABLE f-name AS CHARACTER NO-UNDO FORMAT "x(14)".
DEFINE VARIABLE choice AS CHARACTER NO-UNDO FORMAT "x(50)"
  LABEL "You have selected".
DEFINE VARIABLE list_contents AS CHARACTER NO-UNDO FORMAT "x(200)".
DEFINE VARIABLE dir AS CHARACTER NO-UNDO FORMAT "x(40)"
  LABEL "Please enter a directory pathname".
DEFINE VARIABLE sl AS CHARACTER NO-UNDO
  VIEW-AS SELECTION-LIST INNER-CHARS 15 INNER-LINES 10 SORT.
DEFINe FRAME b sl.
DEFINe FRAME c choice.
DEFINe FRAME d dirlist.
ENABLe dir WITH FRAME d WITH SIDE-LABELS.
ON RETURN OF dir IN FRAME d DO:
  ASSIGN FRAME d dir.
  INPUT STREAM dirlist FROM OS-DIR (dir).
  IMPORT STREAM dirlist f-name.
  list_contents = f-name.
  REPEAT:
    IMPORT STREAM dirlist f-name.
    list_contents = list_contents + "," + f-name.
  END.
  INPUT CLOSE.
sl:LIST-ITEMS IN FRAME b = list_contents.
ENABLe sl WITH FRAME b NO-LABELS TITLE "Please Select a File" WIDTH 50.
END.
ON VALUE-CHANGED OF sl IN FRAME b DO:
  choice = sl:SCREEN-VALUE.
  DISPLAY choice WITH FRAME c SIDE-LABELS.
END.
WAIT-FOR WINDOW-CLOSE OF CURRENT-WINDOW.
```
Notes

- When the selection-list appears, if it contains the value of the associated field or variable, that value is initially highlighted. Otherwise, no value in the selection-list is initially highlighted.

- The LIST-ITEMS option of the SELECTION-LIST phrase requires a list of quoted items ("a", "b", "c"), whereas the LIST-ITEMS attribute of a selection-list requires a quoted list of items ("a, b, c"). Similarly, the LIST-ITEM-PAIRS option of the SELECTION-LIST phrase requires a list of quoted items ("a", "1", "b", "2", "c", "3"); whereas the LIST-ITEM-PAIRS attribute of a selection-list requires a quoted list of items ("a, 1, b, 2, c, 3").

- If you specify the SORT option for a selection-list, then any items you add with ADD-FIRST, ADD-LAST, or INSERT methods are added in sorted order rather than the order you specify.

- In Windows, you can use a mnemonic to transfer focus to the selection-list.

See also SIZE phrase, VIEW-AS phrase

SET statement

Requests input, and then puts the data in the screen buffer frame and in the specified fields or variables. The SET statement is a combination of these statements:

- **PROMPT-FOR** — Prompts the user for data and puts that data into the screen buffer
- **ASSIGN** — Moves data from the screen buffer to the record buffer

**Note:** Does not apply to SpeedScript programming.

Data movement

![Data movement diagram]

SET statement

Syntax

\[
\text{SET} \quad \left[ \begin{array}{l}
\text{STREAM stream} \mid \text{STREAM-HANDLE handle} \\
\text{UNLESS-HIDDEN}
\end{array} \right] \left[ \begin{array}{l}
\{ \begin{array}{l}
\text{field} \mid \text{view-as-phrase} \mid \text{format-phrase} \\
\text{WHEN expression} \\
\text{TEXT ( field \mid \text{format-phrase} \ldots )} \\
\text{field} = \text{expression} \\
\text{constant [ AT n | TO n ]} \\
\wedge \\
\text{SPACE [ ( n ) ]} \\
\text{SKIP [ ( n ) ]}
\end{array} \right] \\
\ldots \\
\text{GO-ON (key-label \ldots )} \\
\text{frame-phrase} \\
\text{editing-phrase} \\
\text{NO-ERROR}
\end{array} \right] ...
\]

\[
\text{SET} \quad \left[ \begin{array}{l}
\text{STREAM stream} \mid \text{STREAM-HANDLE handle} \mid \text{UNLESS-HIDDEN} \\
\text{record} \mid \text{EXCEPT field \ldots } \mid \text{frame-phrase} \\
\text{NO-ERROR}
\end{array} \right]
\]

STREAM stream

Specifies the name of a stream. If you do not name a stream, the AVM uses the unnamed stream. See the DEFINE STREAM statement reference entry and the chapter on alternate I/O sources in OpenEdge Development: Programming Interfaces for more information on streams.

STREAM-HANDLE handle

Specifies the handle to a stream. If handle it is not a valid handle to a stream, the AVM generates a run-time error. Note that stream handles are not valid for the unnamed streams. See the chapter on alternate I/O sources in OpenEdge Development: Programming Interfaces for more information on streams and stream handles.

UNLESS-HIDDEN

Restricts SET to fields whose HIDDEN attribute is FALSE.

field

Represents the name of the field or variable whose value you want to store in the screen buffer and in the field or variable.

In the case of array fields, array elements with constant subscripts are treated as any other field. Array fields with no subscripts are expanded as though you typed in the implicit elements. See the DISPLAY statement reference entry for information on how the AVM handles array fields with expressions as subscripts.
view-as-phrase

Specifies the widget used to represent the field. For more information on `view-as-phrase`, see the VIEW-AS phrase reference entry.

format-phrase

Specifies one or more frame attributes for a field, variable, or expression. For more information on `format-phrase`, see the Format phrase reference entry.

WHEN expression

Sets the field only when `expression` has a value of TRUE. An `expression` is a field name, variable name, or expression whose value is logical.

TEXT

Defines a group of character fields or variables (including array elements) to use automatic word wrap. The TEXT option works with character fields only. When you insert data in the middle of a TEXT field, the AVM wraps data that follows into the next TEXT field, if necessary. If you delete data from the middle of a TEXT field, the AVM wraps data that follows into the empty area. If you enter more characters than the format for the field allows, the AVM discards the extra characters. The character fields must be in the x(n) format.

A blank in the first column of a line marks the beginning of a paragraph. Lines within a paragraph are treated as a group and will not wrap into other paragraphs.

Table 60 lists the keys you can use within a TEXT field, and their actions.

<table>
<thead>
<tr>
<th>Key</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPEND-LINE</td>
<td>Combines the line the cursor is in with the next line.</td>
</tr>
<tr>
<td>BACK-TAB</td>
<td>Moves the cursor to the previous TEXT field.</td>
</tr>
<tr>
<td>BREAK-LINE</td>
<td>Breaks the current line into two lines beginning with the character the cursor is on.</td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Moves the cursor one position to the left and deletes the character at that position. If the cursor is at the beginning of a line, BACKSPACE moves the cursor to the end of the previous line.</td>
</tr>
<tr>
<td>CLEAR</td>
<td>Clears the current field and all fields in the TEXT group that follow.</td>
</tr>
<tr>
<td>DELETE-LINE</td>
<td>Deletes the line the cursor is in.</td>
</tr>
<tr>
<td>NEW-LINE</td>
<td>Inserts a blank line below the line the cursor is in.</td>
</tr>
<tr>
<td>RECALL</td>
<td>Clears fields in the TEXT group and returns initial data values for the group.</td>
</tr>
</tbody>
</table>
In this procedure, the s-com, or Order Comments field is a TEXT field. Run the procedure and enter text in the field to see how the TEXT option works.

### r-text.p

```pascal
DEFINE VARIABLE s-com AS CHARACTER NO-UNDO FORMAT "x(40)" EXTENT 5.

FORM "Shipped    :" Order.ShipDate AT 13 SKIP
  "Misc Info    :" Order.Instructions AT 13 SKIP(1)
  "Order Comments :" s-com AT 1
  WITH FRAME o-com CENTERED NO-LABELS TITLE "Shipping Information".

FOR EACH Customer NO-LOCK, EACH Order OF Customer:
  DISPLAY Customer.CustNum Customer.Name Order.OrderNum Order.OrderDate
    Order.PromiseDate WITH FRAME order-hdr CENTERED.
  UPDATE Order.ShipDate Order.Instructions TEXT(s-com) WITH FRAME o-com.
  s-com = "".
END.
```

### Table 60: Key actions in a TEXT field (2 of 2)

<table>
<thead>
<tr>
<th>Key</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURN</td>
<td>In overstrike mode, moves to the next field in the TEXT group on the screen. In insert mode, the line breaks at the cursor and the cursor is positioned at the beginning of the new line.</td>
</tr>
<tr>
<td>TAB</td>
<td>Moves to the field after the TEXT group on the screen. If there is no other field, the cursor moves to the beginning of the TEXT group.</td>
</tr>
</tbody>
</table>

**field = expression**

Indicates that the value of field is determined by evaluating the expression rather than having it entered on the screen or from a file. An assignment statement is embedded within the SET statement.

**constant AT n**

A constant value that you want to display in the frame. The n is the column in which you want to start the display.

**constant TO n**

A constant value that you want to display in the frame. The n is the column in which you want to end the display.

**^**

Tells the AVM to ignore an input field when input is being read from a file. Thus, the following statement reads a line from an input file and ignores that line:

```
SET ^
```

This is an efficient way to skip over lines.
SPACE \[ ( \ n \ ) \]

Identifies the number \( n \) of blank spaces to insert after the expression on the display. The \( n \) can be 0. If the number of spaces you specify is more than the spaces left on the current line of the frame, the AVM starts a new line and discards any extra spaces. If you do not use this option or do not use \( n \), the AVM inserts one space between items in the frame.

SKIP \[ ( \ n \ ) \]

Identifies the number \( n \) of blank lines to be inserted after the expression is displayed. The \( n \) can be 0. If you do not use this option, a line is not skipped between expressions only if they do not fit on one line. If you use the SKIP option, but do not specify \( n \), or if \( n \) is 0, a new line is started unless it is already at the beginning of a new line.

GO-ON ( keylabel . . . )

Tells the AVM to take the GO action when the user presses any of the keys listed. The keys you list are used in addition to keys that perform the GO action by default or because of ON statements. When you list a key label in the GO-ON option, you use the keyboard label of that key. For example, if you want the AVM to take the GO action when the user presses F1, you use the statement GO-ON(F1). If you list more than one key, separate them with spaces, not commas, as in GO-ON( F1 RETURN ).

frame-phrase

Specifies the overall layout and processing properties of a frame. For more information on frame-phrase, see the Frame phrase reference entry.

editing-phrase

Supported only for backward compatibility.

Identifies processing to take place as each keystroke is entered. This is the syntax for the editing-phrase:

**Syntax**

```
[ label: ] EDITING: statement . . . END.
```

For more information on editing-phrase, see the EDITING phrase reference entry.

**record**

Represents the name of a record buffer. All of the fields in the record, except those with the data type RECID and ROWID, are processed exactly as if you set each individually. The record you name must contain at least one field.

To use SET with a record in a table defined for multiple databases, you must qualify the record’s table name with the database name. See the Record phrase reference entry for more information.

NO-ERROR

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent
side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.
- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.
- Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.
- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.
- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.
- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

**EXCEPT field**

Affects all fields except those fields listed in the EXCEPT phrase.
Examples

The *r-set.p* procedure reads each Item record, displays the *ItemNum* and lets the user enter information for the *ItemName*, *OnHand*, *Allocated*, and *Price* fields. When you run this procedure, notice that it does not display existing values for the *ItemName*, *OnHand*, *Allocated*, and *Price* fields.

### r-set.p

```plaintext
FOR EACH Item:
  DISPLAY Item.ItemNum.
END.
```

On each iteration of the block, the FOR EACH statement reads a single record into the Item record buffer. The DISPLAY statement moves the *ItemNum* from the record buffer to the screen buffer where you can see it. The SET statement prompts for data, stores the data in screen buffers, and moves the data to the record buffer, overwriting whatever is already there. Therefore, even though the *ItemName*, *OnHand*, *Allocated*, and *Price* fields are put into the Item record buffer by the FOR EACH statement, you never see the values for those fields.

The *r-set2.p* procedure displays the *CustNum*, *Name*, and *CreditLimit* for a Customer and lets you change the *CreditLimit* field. The HELP option in the SET statement displays help information at the bottom of the screen when you are changing the *CreditLimit*. The VALIDATE option in the SET statement makes sure that the *CreditLimit* value is greater than 0. If it is not, VALIDATE displays the message “Invalid credit limit.”

### r-set2.p

```plaintext
FOR EACH Customer:
  SET Customer.Name Customer.CreditLimit
    VALIDATE(Customer.CreditLimit > 0, "Invalid credit limit.")
    HELP "Enter a positive credit-limit."
  REPEAT:
    CREATE Order.
    Order.CustNum = Customer.CustNum.
    SET Order.OrderNum Order.ShipDate
      VALIDATE(Order.ShipDate > TODAY, "Ship date too early.").
  END.
END.
```

After you modify *CreditLimit*, the procedure creates an Order for the Customer and assigns the Customer.*CustNum* value to the *CustNum* field in the Order record. The SET statement lets you enter information for the *OrderNum* and *ShipDate* fields. The VALIDATE option in the SET statement makes sure that the *Ship Date* is greater than TODAY.

Notes

- If any *field* is a field in a database record, the SET statement upgrades the record lock condition to EXCLUSIVE-LOCK before updating the record.
- If any *field* is part of a record retrieved with a field list, the SET statement rereads the complete record before updating it.
- SET does not move data into the field or variable if there is no data in the corresponding screen field. There is data in a screen field if a DISPLAY of the field was done or if you enter data into the field. If you set a field or variable that has not been DISPLAYed in the frame and key in blanks, then the field or variable is not changed because the screen field is changed only if the data differs from what was in the frame field.
• When ABL compiles a procedure, it designs all the frames used by that procedure. When you run the procedure, the SET statement puts data into those fields.

• In a SET statement, the AVM first prompts for all specified fields and then assigns the values of those fields, moving from left to right. During this left to right pass of the field list, the AVM processes embedded assignments ($field = assignment$) as it encounters them.

• If you are getting input from a device other than the terminal, and the number of characters read by the SET statement for a particular field or variable exceeds the display format for that field or variable, the AVM returns an error. However, if you are setting a logical field that has a format of y/n and the data file contains a value of YES or NO, the AVM converts that value to “y” or “n”.

• If you type blanks into a field in which data has never been displayed, the ENTERED function returns FALSE and the SET or ASSIGN statement does not update the underlying field or variable. Also, if the AVM has marked a field as entered, and the SET statement prompts for the field again and you do not enter any data, the AVM no longer considers the field an entered field.

• If you use a single qualified identifier with the SET statement, the Compiler first interprets the reference as $dbname.tablename$. If the Compiler cannot resolve the reference as $dbname.tablename$, it tries to resolve it as $tablenamefieldname$.

When using SET to set fields, you must use table names that are different from field names to avoid ambiguous references. See the Record phrase reference entry for more information.

• The SET statement causes the ASSIGN and WRITE events to occur and fires all related database ASSIGN and WRITE triggers. The ASSIGN triggers execute before the WRITE triggers and after the field is actually updated. The WRITE triggers only execute if the ASSIGN triggers do not return an error. If an ASSIGN trigger fails (or executes a RETURN statement with the ERROR option), the SET statement is undone. This means that any changes to the database from that SET statement are backed out. If the SET statement occurs within a transaction, any changes to variables, worktable fields, and temp-table fields are also undone unless they are defined with the NO-UNDO option. Also, if a WRITE trigger fails (or executes a RETURN statement with the ERROR option), the SET statement is undone.

See also  DEFINE STREAM statement, EDITING phrase, Format phrase, Frame phrase, PROMPT-FOR statement, Stream object handle, UPDATE statement

SET-BYTE-ORDER statement

Sets an internal indicator designating the byte-order of the data pointed to by the MEMPTR variable.

Note:  Does not apply to SpeedScript programming.
SET-DB-CLIENT function

Uses the user ID represented by a sealed and validated Client-principal object to set a client user ID for the specified OpenEdge database. Returns TRUE if the user ID is set successfully; otherwise, it returns FALSE.

Note: Using this function overrides the database user ID previously set by either the SET-CLIENT( ) method or the SETUSERID function.
When a user ID is set on a connected database, the AVM uses that user ID to determine whether the user has permission to access tables and fields in that particular database.

Syntax

```
SET-DB-CLIENT( client-principal-handle
                | [ , integer-expression | logical-name | alias ]
                )
```

`client-principal-handle`

A handle to a sealed Client-principal object. The Client-principal object must be created in an authentication domain that is registered in the database connection registry. If the Client-principal object is not sealed, or the handle is the Unknown value (?), the AVM generates a run-time error and the current user ID remains unchanged.

`integer-expression`

The sequence number of a connected database for which to set the user ID. For example, SET-DB-CLIENT(hcp, 1) sets the user ID associated with the specified Client-principal object for the first database, SET-DB-CLIENT(hcp, 2) sets the user ID for the second database, and so on. If you specify a sequence number that does not correspond to a connected database, the AVM generates a run-time error.

`logical-name or alias`

The logical name or alias of a connected database for which to set the user ID. These forms require a quoted character string or a character expression. If you specify a logical name or alias that does not correspond to a connected database, the AVM generates a run-time error.

Notes

- If you do not specify a database, the AVM sets the client user ID for all connected databases (which overrides the user ID previously set by a call to the SET-CLIENT( ) method).

- If the LOGIN-STATE attribute for the sealed Client-principal object is not "LOGIN“, the AVM generates a run-time error and the current user ID remains unchanged.

- The AVM also validates the Client-principal object using the database connection’s domain registry. If not valid, the AVM generates a run-time error and the current user ID remains unchanged.

- You can also use this function, instead of the SETUSERID function, to set a database user ID when the user ID is not in the _User table.

- Calling this method generates an audit event, and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.

See also

Client-principal object handle, SET-CLIENT( ) method, SETUSERID function

**SET-POINTER-VALUE statement**

Sets a variable of type MEMPTR to the value of a particular memory location.
Note: Does not apply to SpeedScript programming.

Syntax

```plaintext
SET-POINTER-VALUE ( memptr-var ) = memptr-value
```

- **memptr-var**
  A reference to a variable defined as MEMPTR.

- **memptr-value**
  An integer that represents a memory location.

Example

The following example calls a DLL routine that returns a pointer to a structure, extracts an address at byte 5 of the structure, uses SET-POINTER-VALUE to assign the address to an ABL MEMPTR, and displays the character string at the address:

```plaintext
DEFINE VARIABLE person_struct AS MEMPTR NO-UNDO. /* pointer to structure */
DEFINE VARIABLE name AS MEMPTR NO-UNDO. /* pointer to name */
SET-SIZE(person_struct) = 8.
RUN person_info (OUTPUT person_struct).
SET-POINTER-VALUE(name) = GET-LONG(person_struct,5).
DISPLAY GET-STRING(name,1) FORMAT "x(50)".
SET-SIZE(person_struct) = 0.
PROCEDURE person_info EXTERNAL "person.dll" PERSISTENT:
   DEFINE OUTPUT PARAMETER person_struct AS MEMPTR.
END PROCEDURE.
```

Notes

- SET-POINTER-VALUE is particularly useful when accessing Windows Dynamic Link Library (DLLs) or UNIX shared library routines from ABL. For more information on DLLs, see the chapter on DLLs in *OpenEdge Development: Programming Interfaces*.

- For more information on the MEMPTR data type, see *OpenEdge Development: Programming Interfaces*.

See also

GET-POINTER-VALUE function, SET-SIZE statement

SET-SIZE statement

Manages memory associated with a MEMPTR variable. This includes allocating and associating a region of memory with an uninitialized MEMPTR variable, setting the size of a region allocated with a Windows dynamic link library (DLL) or UNIX shared library routine for a MEMPTR, and deallocating memory associated with a MEMPTR variable.

Note: Does not apply to SpeedScript programming.
SET-SIZE statement

Syntax

```
SET-SIZE ( memptr-var ) = size
```

*memptr-var*

A reference to a variable defined as MEMPTR.

*size*

An integer expression that specifies the allocated byte size of the region pointed to by *memptr-var*.

Example

In the following example, the SET-SIZE statement allocates 8 bytes of memory, associates the memory with the *ElipRegion* variable, and then initializes the region with four SHORT (2-byte) values:

```
r-setsiz.p
```

```
DEFINE VARIABLE ElipRegion AS MEMPTR NO-UNDO.
ASSIGN
  SET-SIZE(ElipRegion) = 8
  PUT-SHORT(ElipRegion, 1) = 10
  PUT-SHORT(ElipRegion, 3) = 10
  PUT-SHORT(ElipRegion, 5) = 200
  PUT-SHORT(ElipRegion, 7) = 50.
```

Notes

- If *memptr-var* has no memory allocated to it (is uninitialized), then the SET-SIZE statement allocates a memory region of the specified size.

- If a MEMPTR variable is returned from a DLL or UNIX shared library routine that also allocates a memory region to it, then the SET-SIZE statement initializes the size of the existing region. The AVM does not allocate a new region. This allows the AVM to perform bounds checking on references to MEMPTR regions allocated outside ABL.

**Caution:** You must know and specify the exact size of the memory region returned by the DLL routine from the type of structure it allocates. An incorrect size can result in data loss.

- If the specified size is 0, the SET-SIZE statement deallocates (frees) any memory associated with *memptr-var*, making it available to reference a new memory region.

- If the specified size is greater than 0 and *memptr-var* is fully initialized (associated with a memory region of a specified size), the SET-SIZE statement has no effect and leaves *memptr-var* unchanged.

- After initializing a MEMPTR variable, you can obtain the address of (or pointer to) the region associated with the variable using the GET-POINTER-VALUE function. Use this to build structures that contain pointers to other structures, as required by some DLL or UNIX shared library routines.

- For more information on accessing DLL routines from ABL, see *OpenEdge Development: Programming Interfaces*.

See also

GET-POINTER-VALUE function, GET-SIZE function
**SETUSERID function**

Returns a TRUE value and assigns the user ID to the user if the user ID and password supplied to the SETUSERID function are in the _User table. If the user ID is not in the _User table or the password is incorrect, SETUSERID returns a FALSE value and does not assign the user ID to the user.

**Note:** Using this function overrides the database user ID previously set by either the SET-CLIENT() method or the SET-DB-CLIENT function.

**Syntax**

```
SETUSERID ( userid , password [ , logical-dbname ] )
```

**userid**

A constant, field name, variable name, or expression that results in a character value that represents the user's user ID. If you use a constant, you must enclose it in quotation marks (" ").

**password**

A constant, field name, variable name, or expression that results in a character value that represents the user’s password. If you use a constant, you must enclose it in quotation marks.

**logical-dbname**

The logical name of the database where you want to check and set your user ID. The logical database name must be a character string enclosed in quotes, or a character expression. If you do not specify this argument, the Compiler inserts the name of the database that is connected when the procedure is compiled. If you omit this argument and more than one database is connected, it results in a Compiler error.

**Example**

To use the login.p procedure that is provided with ABL, you must define user IDs and passwords for those users who are authorized to access the database.
The login.p procedure uses the SETUSERID function to check the value of the user ID and password that a user enters. If the value of the function is FALSE, the procedure allows the user another try. The user has three tries to log in. The first time, the tries variable is 0; tries is 1 the second time, and 2 the third. The third time, tries is greater than 1 and the procedure exits from ABL with the QUIT statement.

Notes

- Use the Userid (-U) parameter together with the Password (-P) parameter. The AVM checks the _User table for the userid supplied with the -U parameter. When it finds that userid, it compares the password supplied with the -P parameter with the password in the _User table. If the two passwords match, the AVM assigns that userid to the ABL session.

- Under the following conditions, the SETUSERID function returns a value of FALSE and does not assign a user ID to the user:
  - There are no entries in the _User table.
  - There is no _User record with the same user ID as the one supplied with the SETUSERID function.
  - The password supplied with the SETUSERID function does not match the password in the _User table record of the specified user ID.

- When using the SETUSERID function, ABL returns a compiler error under the following conditions:
  - There is no database connected.
  - The logical-dbname argument is omitted, and more than one database is currently connected.

- When specifying the logical-dbname argument, you must provide the name of the logical database, not the physical database.
SETUSERID function

- SETUSERID encodes the *password* argument and then compares the result with the value stored in the _User_.password field of the _User table.

- After SETUSERID returns a value of TRUE and assigns a user ID to a user:
  - ABL uses that user ID when the user compiles procedures.
  - Subsequent uses of the USERID function return the assigned user ID.

- If the root user ID does not exist in the _User table, SETUSERID returns a value of FALSE when supplied with a userid of root. If the _User table does have a root entry, the user who assumes that user ID has all the privileges associated with the root user ID on UNIX.

- You must create a blank user ID (""") if you want to set the user ID to a null value.

- Table 62 shows how ABL determines a user ID on UNIX.

**Table 62: Determining a UNIX user ID**

<table>
<thead>
<tr>
<th>Are there records in the _User table?</th>
<th>Are the -U and -P startup options supplied?</th>
<th>User ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>YES</td>
<td>Error: -U and -P not allowed unless there are entries in the _User table.</td>
</tr>
<tr>
<td>NO</td>
<td>NO</td>
<td>UNIX user ID.</td>
</tr>
<tr>
<td>YES</td>
<td>NO</td>
<td>&quot;&quot; (blank user ID).</td>
</tr>
<tr>
<td>YES</td>
<td>YES</td>
<td>If the -U <em>userid</em> and -P <em>password</em> match those in the _User table, use that <em>userid</em>. Otherwise, do not assign a user ID.</td>
</tr>
</tbody>
</table>

- Table 63 shows how ABL determines a user ID in Windows.

**Table 63: Determining a Windows user ID** *(1 of 2)*

<table>
<thead>
<tr>
<th>Are there records in the _User table?</th>
<th>Are the -U and -P startup options supplied?</th>
<th>User ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>YES</td>
<td>Error: -U and -P not allowed unless there are entries in the _User table.</td>
</tr>
<tr>
<td>NO</td>
<td>NO</td>
<td>&quot;&quot; (blank user ID) or operating system user ID if available.</td>
</tr>
</tbody>
</table>
SHA1-DIGEST function

Hashes the specified data using the United States Government Secure Hash Algorithm (SHA-1), and returns a 20-byte binary message digest value as a RAW value.

Syntax

\[
\text{SHA1-DIGEST( } \text{data-to-hash} \ [ , \ \text{hash-key} \ ] \ )
\]

**data-to-hash**

The source data to hash. The data may be of type CHARACTER, LONGCHAR, RAW, or MEMPTR. If the data is a CHARACTER or LONGCHAR value, the AVM converts it to UTF-8 (which ensures a consistent value regardless of code page settings). To avoid this automatic conversion, specify a RAW or MEMPTR value.

**hash-key**

An optional key value to use in the hash operation. The key may be of type CHARACTER, LONGCHAR, RAW, or MEMPTR. If the key is a CHARACTER or LONGCHAR value, the AVM converts it to UTF-8 (which ensures a consistent value regardless of code page settings). To avoid this automatic conversion, specify a RAW or MEMPTR value. This key value is combined with the source data before the hash operation begins.

---

**Table 63: Determining a Windows user ID**

<table>
<thead>
<tr>
<th>Are there records in the _User table?</th>
<th>Are the -U and -P startup options supplied?</th>
<th>User ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>NO</td>
<td>&quot;&quot; (blank user ID).</td>
</tr>
<tr>
<td>YES</td>
<td>YES</td>
<td>If the -U userid and -P password match those in the _User table, use that user ID. Otherwise, do not assign a user ID.</td>
</tr>
</tbody>
</table>

- See *OpenEdge Development: Programming Interfaces* and *OpenEdge Data Management: Database Administration* for more information on user privileges.
- Calling this method generates an audit event, and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.
- Once an initial database connection is established, you can also use the SET-CLIENT( ) method (on the SECURITY-POLICY system handle) or the SET-DB-CLIENT function to set the user ID for the connection.

See also

CONNECT statement, SET-CLIENT( ) method, SET-DB-CLIENT function, USERID function
If the hash-key value contains a null character, the null character is included in the hash operation.

**See also** MD5-DIGEST function

---

### SHOW-STATS statement

Writes procedure call statistics to the `proc.mon` output file if you specify the Statistics with Cross-Reference (`-yx`) parameter. It also writes procedure access and usage statistics to the `client.mon` output file if you specify the Statistics (`-y`) parameter, Statistics with `CTRL+C` (`-yc`) parameter, Segment Statistics (`-yd`) parameter, or Statistics with Cross-Reference (`-yx`) parameter. If you specify Segment Statistics (`-yd`), it also displays statistics for each code segment.

Ordinarily, when you specify these startup parameters, the AVM writes the statistics to the output files at the end of your ABL session. This might not be what you want. For example, if you start ABL using the `-y` or `-yc` parameters, you might want to view the execution buffer statistics as they occur during your ABL session. With SHOW-STATS, you can force the AVM to write the statistics at a specific time, instead of at session end. For more information on these startup parameters, see *OpenEdge Deployment: Startup Command and Parameter Reference*.

The SHOW-STATS statement also writes the value of the `STARTUP-PARAMETERS` attribute to the `client.mon` output file.

**Syntax**

```
SHOW-STATS [ CLEAR ]
```

**CLEAR**

Resets all counters and timers that the AVM uses to monitor the procedure call, procedure access, and usage statistics.

**Example**

This procedure runs the Data Dictionary and writes the procedure call, procedure access, and usage statistics to the `proc.mon` and `client.mon` output files:

```
r-stats.p

RUN dict.p.
SHOW-STATS.
```

**Notes**

- If you use the SHOW-STATS statement without specifying the Statistics (`y`) parameter, the AVM opens the `client.mon` file as if you were dynamically specifying `-y`. However, the first SHOW-STATS statement that you use does not send any statistics to the `client.mon` file; it only opens the file. All subsequent SHOW-STATS statements, however, send procedure access and usage statistics to the file. But since you did not specify `-y` at startup, the AVM does not write any startup parameter statistics to the `client.mon` file.

- You must specify the Statistics with Cross-Reference (`-yx`) parameter, if you want the SHOW-STATS statement to write procedure call statistics to the `proc.mon` file.
SIZE phrase

Specifies the width and height of a widget. You can express the dimensions in either character units or pixels.

Syntax

\[
\{ \text{SIZE} \mid \text{SIZE-CHARS} \mid \text{SIZE-PIXELS} \} \ width \ BY \ height
\]

\[
\{ \text{SIZE} \mid \text{SIZE-CHARS} \}
\]

Specifies that the unit of measure is characters.

\text{SIZE-PIXELS}

Specifies that the unit of measure is pixels.

\text{width}

Specifies the width of the widget. If the units are characters, \text{width} must be a decimal constant. If the units are pixels, \text{width} must be an integer constant.

\text{height}

Specifies the height of the widget. If the units are characters, the value \text{height} must be a decimal constant. If the units are pixels, \text{height} must be an integer constant.

Example

The following example uses SIZE phrases to set the initial dimensions of the rectangle \text{rec} and to set the dimensions of the frame \text{sz-frame}. When you choose the \text{b_size} button, the rectangle is randomly resized.

\text{r-size.p}

```
DEFINE BUTTON b_quit LABEL "Quit"
  TRIGGERS:
    ON CHOOSE QUIT.
  END.

DEFINE BUTTON b_size LABEL "Size It".
DEFINE RECTANGLE rec SIZE 5 BY 5.
DEFINE FRAME butt-frame
  b_size b_quit
  WITH CENTERED ROW SCREEN-LINES - 2.

DEFINE FRAME sz-frame
  SKIP(1) SPACE(1) rec
  WITH SIZE 80 BY 10 TITLE "The rectangle is 5 by 5".

ON CHOOSE OF b_size IN FRAME butt-frame
  ASSIGN
    rec:WIDTH-CHARS IN FRAME sz-frame =
      RANDOM(1, FRAME sz-frame:WIDTH-CHARS - 3)
    rec:HEIGHT-CHARS = RANDOM(1, FRAME sz-frame:HEIGHT-CHARS - 2)
    FRAME sz-frame:TITLE = "The rectangle is " + STRING(rec:WIDTH-CHARS) + 
      " by " + STRING(rec:HEIGHT-CHARS).ENABLE rec WITH FRAME sz-frame.

  ENABLE b_size b_quit WITH FRAME butt-frame.
  WAIT-FOR CHOOSE OF b_quit IN FRAME butt-frame.
```
Notes

- ABL supports fractional character units. Therefore, if you express dimensions in characters, the width and height values can include up to two decimal places.
- For SpeedScript, the PIXEL options are not valid.

See also

COMBO-BOX phrase, DEFINE BROWSE statement, DEFINE BUTTON statement, DEFINE IMAGE statement, DEFINE RECTANGLE statement, EDITOR phrase, Frame phrase, RADIO-SET phrase, SELECTION-LIST phrase, SLIDER phrase

SLIDER phrase

Describes a slider representation of a field or variable. A slider is a graphical representation of a numeric range. It is composed of a rectangular area that contains a line or trackbar. A marker or pointer within the region indicates the current value. The SLIDER phrase is an option of the VIEW-AS phrase.

Note: Does not apply to SpeedScript programming.

Syntax

```
VIEW-AS SLIDER
  MAX-VALUE max-value MIN-VALUE min-value
  [ HORIZONTAL | VERTICAL ]
  [ NO-CURRENT-VALUE ]
  [ LARGE-TO-SMALL ]
  [ TIC-MARKS { NONE | TOP | BOTTOM | LEFT | RIGHT | BOTH }]
  [ FREQUENCY n ]
  [_TOOLTIP tooltip ]
  [ size-phrase ]
```

MAX-VALUE max-value MIN-VALUE min-value

Sets the range of values for the slider. Both max-value and min-value must be integer constants. Depending on the windowing system in use, the maximum value, minimum value, or both can be displayed with the slider. If you do not specify either a minimum value or a maximum value, the default is 0. Max-value must be greater than min-value.

In Windows only, you can use the MAX-VALUE and MIN-VALUE options with the LARGE-TO-SMALL option to indicate that the slider’s maximum display value displays first and the minimum value displays last as you move the slider control.

HORIZONTAL | VERTICAL

Specifies the orientation of the slider. If the orientation is VERTICAL, the slider displays with the minimum value at the bottom and the maximum value at the top. The user can then change the value by moving the trackbar up or down. If the orientation is HORIZONTAL (the default), the slider displays with the minimum value at the left and the maximum value at the right. The user can then change the value by moving the bar left or right.
**NO-CURRENT-VALUE**

The default is to display the current value for a given position on the slider control. The NO-CURRENT-VALUE option allows you to override this default behavior to indicate that the slider will not automatically display the current value of the slider.

For example, if the MIN-VALUE is 10, the default is to display the value 10 when the slider is first realized, and to update the displayed value whenever a user moves the slider trackbar.

The NO-CURRENT-VALUE option is supported in Windows only.

**LARGE-TO-SMALL**

The default numeric range that a slider can display is small (minimum) to large (maximum). The LARGE-TO-SMALL option allows you to override this default behavior as follows:

- When the slider is positioned horizontally, the left-most position on the trackbar displays the maximum value and the right-most position displays the minimum value.
- When the slider is positioned vertically, the bottom-most position on the trackbar displays the maximum value and the top-most position displays the minimum value.

The LARGE-TO-SMALL option is supported in Windows only.

**TIC-MARKS**

Enables the display of short hash marks on the outside of a slider to help indicate the movement of the trackbar with the slider widget. The default is not to display tic marks. If you specify the TIC-MARKS option, it is assumed that you are using new code to create a slider, and the trackbar on the slider widget will be relatively large.

However, if you leave the TIC-MARKS option out, ABL assumes that you are migrating old code, and the default size of the slider is the size originally defined for the slider in the old code.

If you want to use the large trackbar but do not want tic marks to display, specify TIC-MARKS NONE.

To implement the TIC-MARKS option, you must also specify on which side, or sides, of the trackbar tick-marks display by using the additional TOP, BOTTOM, LEFT, RIGHT, or BOTH qualifying options.

The TIC-MARKS option is supported in Windows only.

**FREQUENCY**

Used only with the TIC-MARKS option, indicates the incremental display of the TIC-MARKS. For example, if you indicate a frequency of 5, a tic mark displays in every fifth position along the slider bar.

The FREQUENCY option is supported in Windows only.
TOOLTIP tooltip

Allows you to define a help text message for a text field or text variable. The AVM automatically displays this text when the user pauses the mouse pointer over a text field or text variable for which a ToolTip is defined.

You can add or change the TOOLTIP option at any time. If TOOLTIP is set to “” or the Unknown value (?), then the ToolTip is removed. No ToolTip is the default. The TOOLTIP option is supported in Windows only.

size-phrase

Specifies the outside dimensions of the slider widget. This is the syntax for size-phrase:

Syntax

{ SIZE | SIZE-CHARS | SIZE-PIXELS } width BY height

For more information, see the SIZE phrase reference entry.

Example

The following procedure displays a slider with tic-marks noted every tenth position, and prompts the user to pick an integer value. After the user picks an integer, the program displays in a separate frame the text “You selected” followed by the value.

r-slide.p

```ABL
DEFINE VARIABLE choice AS INTEGER NO-UNDO LABEL "You selected".
DEFINE VARIABLE a AS INTEGER NO-UNDO.
UPDATE a VIEW-AS SLIDER MAX-VALUE 100 MIN-VALUE 1 SIZE-CHAR 33 BY 3 TIC-MARKS BOTTOM FREQUENCY 10 LABEL "Slide to select an integer. Then press GO."
WITH FRAME f Three-D.
choice = a.
DISPLAY choice WITH FRAME b SIDE-LABELS THREE-D.
PAUSE.
```

Notes

- If the slider is too short, the user might not be able to select from the full range of values.
- If you display the slider horizontally, the width value determines the length of the slider, and the height value adds white space above and below the slider; similarly, if you display the slider vertically, the height value determines the length of the slider, and the width value adds white space on either side of the slider.
- Note that Windows allows a user to transfer focus to the slider by pressing ALT and one of the letters in the label.
- In character interfaces, a slider widget has a minimum width that is dependent on the specified maximum value (MAX-VALUE attribute). The minimum height for a slider widget in a character interface is 2 character units. You can specify a value as low as 1.5 character units for the height of a slider in a character interface; however, ABL rounds the value up to 2 character units.

See also VIEW-AS phrase
**SQRT function**

Returns the square root (as a DECIMAL value) of an expression you specify.

**Syntax**

```
SQRT ( expression )
```

*expression*

A numeric expression. If the value of the expression is negative, SQRT returns the
Unknown value (?).

**Example**

This procedure prompts for a number and then displays the square root of that number:

```
r-sqrt.p

DEFINE VARIABLE iNum AS INTEGER NO-UNDO FORMAT ">,>>,9"
   LABEL ">Enter a number between 1 and 9,999".

REPEAT WITH SIDE-LABELS CENTERED
   TITLE "SQUARE ROOT GENERATOR" COLUMN 20 1 DOWN:
   DISPLAY SKIP(2).
   SET iNum SKIP(2).
   DISPLAY ">The square root of " + STRING(iNum) + "> is" FORMAT ">x(27)"
      SQRT(num) FORMAT ">>,9999".
END.
```

**SSL-SERVER-NAME function**

Returns the digital certificate subject name for an OpenEdge database connected via SSL. If a
database connection does not exist or the connection is not using SSL, this function returns the
Unknown value (?).

**Syntax**

```
SSL-SERVER-NAME ( logical-database-name )
```

*logical-database-name*

A quoted character string or character expression that specifies the database by its logical
name.

**Example**

The following example returns the digital certificate subject name of the database with the
logical name *mydb*:

```
SSL-SERVER-NAME (mydb).
```

**See also**  Server object handle, Socket object handle
STATUS statement

Specifies the text that appears in the status line of a window. The AVM displays the following default messages on that line:

- When a procedure is blocked and is waiting for the user to enter data into a frame field, the status message is “Enter data or press end-error to end,” where end-error is the key label for the END-ERROR key.
- When a procedure reaches a PAUSE statement, the status message is “Press space bar to continue.”
- While a procedure is not blocked for input, the status message is blank.

**Note:** Does not apply to SpeedScript programming.

Syntax

```
STATUS
{   DEFAULT [ expression ]
   | INPUT [ OFF | expression ]
}
[ IN WINDOW window ]
```

**DEFAULT expression**

Replaces the default status message when a user is running a procedure (the default status message is blanks). The expression must be character and must be enclosed in quotes if it is a constant. If you do not specify an expression, the AVM resets the STATUS DEFAULT line to its original state. The STATUS DEFAULT is a maximum of 63 characters.

**INPUT OFF**

Tells the AVM not to display an input status message.

**INPUT expression**

Replaces the default status message when a user is entering data into a frame field. The expression must be character and must be enclosed in quotes if it is a constant. If you do not specify an expression, the AVM resets the STATUS INPUT line to its original state.

**IN WINDOW window**

Specifies the window in which to set the status message. If you omit the IN WINDOW phrase, the STATUS statement applies to the current window.

**Example**

This procedure replaces the default status messages with two other messages:
STOP statement

r-status.p

```plaintext
STATUS DEFAULT "All Around Sports Order Processing System".
STATUS INPUT "Enter data, or use the " + KLABEL("END-ERROR") + " key to exit".
FOR EACH Customer:
  DISPLAY Customer.Name.
  FOR EACH Order OF Customer:
    UPDATE Order.OrderNum Order.PromiseDate Order.OrderDate Order.ShipDate.
    END.
  UPDATE Customer.CreditLimit.
END.
```

Notes

• After you use the STATUS DEFAULT, STATUS INPUT OFF, or STATUS INPUT statement during a session, that statement is in effect for all the procedures run in that session, unless it is overridden by other STATUS statements in those procedures, or until you return to the Procedure Editor.

• You cannot use the STATUS statement to change the default status messages displayed while you are in the Procedure Editor.

• You can use the PAUSE statement to override the default status message displayed when the AVM encounters a PAUSE statement.

• When you use the HELP attribute to display help text for a widget, the AVM overwrites the status text with the HELP text.

See also  MESSAGE statement, PAUSE statement

STOP statement

Signals the STOP condition in the current block. By default, the STOP condition stops processing a procedure, backs out the active transaction, and unwinds the call stack until it returns to the startup procedure or the Procedure Editor. You can change this behavior by including the ON STOP phrase on a block statement.

Syntax

```
STOP
```

Examples

In any procedure, the outermost block that updates the database is the system transaction. In this procedure, the first iteration of the FOR EACH block starts a system transaction. The transaction ends when that iteration ends. Another transaction starts at the start of the next iteration. After you update the credit-limit field, the AVM prompts you to STOP. If you enter yes, the STOP statement stops the procedure and undoes any database modifications made in that transaction, as shown:
When you add the ON STOP phrase to the block statement of the previous procedure, it changes the default behavior of the STOP statement. In this procedure, the AVM allows you to re-enter the record when you choose to stop:

```
r-stop.p
DEFINE VARIABLE ans AS LOGICAL NO-UNDO.
FOR EACH Customer:
    UPDATE Customer.CreditLimit.
    ans = FALSE.
    MESSAGE "Stopping now undoes changes to this record."
    MESSAGE "Do you want to stop now?" UPDATE ans.
    IF ans THEN STOP.
END.
```

```
r-stop2.p
DEFINE VARIABLE ans AS LOGICAL NO-UNDO.
FOR EACH Customer ON STOP UNDO, RETRY:
    UPDATE Customer.CreditLimit.
    ans = FALSE.
    MESSAGE "Stopping now undoes changes to this record."
    "Do you want to stop now?"
    VIEW-AS ALERT-BOX QUESTION BUTTONS YES-NO UPDATE ans.
    IF ans THEN STOP.
END.
```

**Notes**

- Unless you coded an ON STOP phrase, the STOP statement continues to back out of all blocks on the call stack.

- Almost all STOP conditions are trappable with the ON STOP phrase. In two cases, the AVM may ignore ON STOP phrases. First, if the AVM executes a procedure that relies on a lost database connection, the AVM raises the STOP condition and unwinds the call stack until it gets to a level above all references to the lost database. If it encounters an ON STOP before this point it ignores it. If it encounters an ON STOP phrase after this point, then the AVM executes the ON STOP. Similarly, if the AVM encounters an I/O blocking statement inside a user-defined function or a non-void method, the STOP condition is raised, and the AVM unwinds the procedure stack ignoring ON STOP phrases until it gets to a point above the user-defined function or non-void method call.

- If you use the Startup Procedure (-p) parameter to start the ABL session, and if the startup procedure is still active, the default STOP action restarts the procedure.

- A terminal user can initiate the STOP condition by pressing **STOP**. This is usually mapped to **CTRL+BREAK** (Windows) or **CTRL+C** (UNIX). The actual mapping depends on your terminal and system configuration.
STRING function

STRING function

r-stop2.p

```abl
DEFINE VARIABLE ans AS LOGICAL NO-UNDO.

FOR EACH Customer ON STOP UNDO, RETRY:
  UPDATE Customer.CreditLimit.
  ans = FALSE.
  MESSAGE "Stopping now undoes changes to this record."
  "Do you want to stop now?"
  VIEW-AS ALERT-BOX QUESTION BUTTONS YES-NO UPDATE ans.
  IF ans THEN STOP.
END.
```

Converts a value of any data type into a character value.

Syntax

```plaintext
STRING ( source [, format ] )
```

source

An expression of any data type that you want to convert to a character value.

format

The format you want to use for the new character value. This format must be appropriate to the data type of source. If you do not use this argument, ABL uses the EXPORT format for all data types (except DATETIME and DATETIME-TZ, in which case it uses the default display format). This is useful if you want to produce left-justified numbers. For information on data display formats, see OpenEdge Getting Started: ABL Essentials.

Example

In the example procedure, the TIME function returns the number of seconds since midnight. The first DISPLAY statement in this procedure uses the STRING function to convert that value into hours and minutes. TIME is the value and “HH:MM AM” is the format used to display the result of the STRING function.

The second DISPLAY statement displays some Customer information. It uses the concatenation (+) operator to join together the values of the City, State, and PostalCode fields. If these fields were not joined together, the spacing would be different for each Customer address depending on the length of the city name.

r-string.p

```abl
DISPLAY SKIP(2) "The time is now" STRING(TIME,"HH:MM AM") SKIP(2)
WITH NO-BOX NO-LABELS CENTERED.

FOR EACH Customer NO-LOCK:
  DISPLAY Customer.Name + "  --" +
  STRING(Customer.CustNum, ">>>9") FORMAT "x(30)" AT 1
  Customer.Address AT 33
  FORMAT "x(22)" AT 33 SKIP(1)
  WITH NO-BOX NO-LABELS CENTERED.
END.
```
When you concatenate character fields, the AVM creates a new character field, at least for the duration of the procedure. The default display format for character expressions such as that resulting from the concatenation is x(8). This means that the AVM allows only 8 spaces for displaying the concatenation of the City, State, and PostalCode fields. The FORMAT x(22) option overrides that default x(8) format, telling the AVM to set aside 22 spaces for displaying the concatenation of the City, State, and PostalCode fields.

**Notes**

- The STRING function is double-byte enabled. The source argument can contain double-byte data.

- If source is an integer and format begins HH:MM or HH:MM:SS, STRING formats the source as a time. If the hour is greater than or equal to 12 and there is an A or an a in format, STRING subtracts 12 from the hour and converts the A or the a to a P or p (for A.M. and P.M.). The hour 0 is treated as 12 a.m., and noon is treated as 12 p.m. If you use AM/PM format, HH is replaced by a leading blank and a digit if the hour is between 0 and 9.

  If seconds (SS) are not in the format, then the time is truncated to hours and minutes.

- If source is a RAW value, you must specify an appropriate format to return the character string representation.

- When source is a DATETIME or DATETIME-TZ expression, the STRING function converts the expression to a character value in the specified format. If source is a DATETIME expression, and a time zone offset is present in the format string, the character value contains the time zone offset of the session. If source is a DATETIME-TZ expression, and time zone offset is not present in the format string, the character value contains the local date and time relative to the time zone of the DATETIME-TZ value.

- The STRING function converts a DATE, and the date part of a DATETIME or DATETIME-TZ, using the format specified by the DATE-FORMAT attribute or the Date Format (-d) startup parameter.

  For more information about the Date Format (-d) startup parameter, see *OpenEdge Deployment: Startup Command and Parameter Reference*.

- You can use the STRING function to convert an object reference for a class instance to a character value. The STRING function implicitly calls the ToString( ) method of the class to convert the specified object reference.

DECIMAL function, INTEGER function, ToString( ) method

---

**SUBSCRIBE statement**

Creates a subscription to an ABL named event.

**Note:** ABL named events are completely different from the key function, mouse, widget, and direct manipulation events described in the “Handle-based Object Events Reference” section on page 1827. They are also different from the class events described in the “Class Events Reference” section on page 1953.

**Syntx**

```plaintext
SUBSCRIBE [ PROCEDURE subscriber-handle ] [ TO ] event-name
{ IN publisher-handle | ANYWHERE }
[ RUN-PROCEDURE local-internal-procedure ] [ NO-ERROR ]
```

**PROCEDURE** `subscriber-handle`

A procedure or handle representing the subscriber.

The PROCEDURE option lets one procedure create a subscription on behalf of another. For example, if you want procedure A to create a subscription on behalf of procedure B, set `subscriber-handle` to the procedure handle of B.

If the PROCEDURE option does not appear, the AVM creates a subscription on behalf of THIS-PROCEDURE, the procedure that contains the SUBSCRIBE statement.

**TO** `event-name`

A quoted string or a character expression representing the name of the event.

**IN** `publisher-handle`

Subscribes to the named events published by `publisher-handle`.

If `publisher-handle` is not a valid procedure or widget handle at the time the SUBSCRIBE statement executes, the AVM reports a run-time error unless you specify the NO-ERROR option.

**ANYWHERE**

Subscribes to named events published within the ABL session, regardless of the publisher.

**RUN-PROCEDURE** `local-internal-procedure`

A quoted string or character expression representing the name of an internal procedure that resides within the subscribing program. The AVM runs `local-internal-procedure` when the named event occurs.

If the RUN-PROCEDURE option does not appear, when the named event occurs, the AVM runs an internal procedure with the same name as the named event.

**Note:** The RUN-PROCEDURE option lets you create a subscription when the event name and the procedure name do not match, or when you must subscribe to two different events that have the same name.

When the named event occurs, the AVM RUNs each subscriber’s local internal procedure, passing the parameters, if any. The order in which the AVM notifies subscribers is undefined. The AVM always performs this RUN with an implicit NO-ERROR, and logs errors to the ERROR-STATUS system handle.

**NO-ERROR**

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent
side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

For the SUSCRIBE statement with NO-ERROR, this option tells the AVM not to report a run-time error if publisher-handle or subscriber-handle is not a valid procedure handle, or if the AVM cannot evaluate an event-name expression.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.
- Check if the ERROR-STATUS:NUMMESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.
- Use ERROR-STATUS:GETMESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.
- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.
- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.
- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.
Example

For an example, see the reference entry for the PUBLISH statement.

Notes

- Within the local internal procedure, you can get a handle to the publisher of the named event by using the SOURCE-PROCEDURE system handle. For more information on the SOURCE-PROCEDURE system handle, see the reference entry.

- If the AVM detects a redundant SUBSCRIBE statement—that is, a SUBSCRIBE statement with the same event name, and either the same publisher handle or the same ANYWHERE option—the AVM does not report an error.

- If event-name is a string containing spaces or is otherwise not a standard ABL name, use one of the following techniques:
  - Use the RUN-PROCEDURE option to assign the local internal procedure a more conventional name.
  - When you define local-internal-procedure, put its name in quotes, as in the following example:

```
PROCEDURE "spaced event":
```

PUBLISH statement, PUBLISHED-EVENTS attribute, Subscribe( ) event method, UNSUBSCRIBE statement

**SUBSTITUTE function**

This function returns a character string that is made up of a base string plus the substitution of arguments in the string. It allows you to use a single string in place of concatenated strings. It is designed to simplify the task of translating an application from one language to another. This function is similar to the sprintf function in the C programming language.

Syntax

```
SUBSTITUTE ( base-string [ , arg ] ... )
```

**base-string**

A CHARACTER or LONGCHAR variable optionally containing substitution parameters of the form &n, where n is an integer between 1 and 9, inclusive.

**arg**

A constant, field name, variable, or expression that results in a CHARACTER or LONGCHAR value. These argument values replace substitution parameters in base-string.

Examples

These statements display the same message:

```
MESSAGE SUBSTITUTE("There were &1 records in &2 tables", rec-count, table-count).
```
You can alter the position of the substitution parameters, as in this statement:

```
SUBSTITUTE("&2 comes before &1", "Friday", "Monday").
```

**Notes**

- The SUBSTITUTE function is double-byte enabled. The specified `base-string` and `arg` values can contain double-byte characters.
- To include an ampersand character in `base-string`, enter two ampersands (`&&`).
- The character following the ampersand character must be a digit, or the AVM returns a run-time error.
- To display the result of the SUBSTITUTE function in a frame, you must specify FORMAT or accept the default format of X(8).
- If you use a substitution parameter in `base string` but do not specify a corresponding argument, the AVM replaces the substitution parameter with an empty string.
- The SUBSTITUTE function converts Unknown value (?) parameters into empty strings.
- Any substitution parameter can appear multiple times in `base string`. For example:

```
phrase = "finish on time".
DISPLAY SUBSTITUTE("When I say &1, I mean &1!", phrase) FORMAT "X(70)".
```

The previous code fragment displays the following line:

```
When I say finish on time, I mean finish on time!
```

**See also**  
REPLACE function

---

### SUBSTRING function

Extracts a portion of a character string from a field or variable.

**Syntax**

```
SUBSTRING ( source , position [ , length [ , type ] ] )
```

**source**

A CHARACTER or LONGCHAR expression from which you want to extract characters or bytes.
**SUBSTRING function**

**position**

An integer expression that indicates the position of the first character you want to extract from `source`.

**length**

An integer expression that indicates the number of characters you want to extract from `source`. If you do not use the `length` argument or specify -1 as the length, `SUBSTRING` uses the remainder of the string from the specified `position`.

**type**

A CHARACTER expression that directs ABL to interpret the specified `position` and `length` values as character units, bytes, or columns. A double-byte character registers as one character unit. By default, ABL interprets the specified `position` and `length` values as character units.

There are four valid types: "CHARACTER," "FIXED," "COLUMN," and "RAW." The expression "CHARACTER" specifies character units. The expression "FIXED" specifies that `position` is in character units and the length is in bytes, but directs `SUBSTRING` to yield only whole characters. That is, if the last byte or bytes represent part of, but not all of, a multi-byte character, these bytes are excluded. The expression "COLUMN" specifies display or print character-columns. The expression "RAW" specifies bytes. If you specify the `type` as a constant expression, ABL validates the type specification at compile time. If you specify the `type` as a non-constant expression, the AVM validates the type specification at run time.

**Note:** If `source` is a LONGCHAR expression, "CHARACTER" is the only valid type and the default type.

**Example**

The `r-substr.p` procedure uses the `SUBSTRING` function to create invoice numbers. You supply a starting invoice number. The first `SUBSTRING` function produces the first two characters of today’s date; the second `SUBSTRING` function produces the last two characters of today’s date. The procedure concatenates these four characters to a hyphen and the number you entered to produce an invoice number.
**SUBSTRING statement**

Inserts content from a specified expression into a field or variable, optionally replacing existing characters, bytes, or columns.

**Syntax**

```
SUBSTRING ( target, position [, length [, type ] ] ) = expression
```

**target**

A field or variable of type CHARACTER or LONGCHAR in which you want to store the specified expression.

**position**

An integer expression that indicates the position in the target where you want to start storing the expression. If the position is longer than the target, ABL pads the target with blanks to equal the length of the position.

**length**

An integer expression that indicates the number of positions you want to replace in the target. If you specify a length of 0, the entire expression is inserted at the position and everything else moves to the right. If you do not use the length argument or specify -1 as the length, SUBSTRING puts the entire expression into the target, replacing an equal amount of the target.

---

**See also**

OVERLAY statement, SUBSTRING statement
The SUBSTRING statement uses the SUBSTRING statement to replace a segment of text with the expression in the SUBSTRING statement XXXXXXXXX. The procedure first displays the text you can work with in the Original Text frame. Then the procedure prompts you for the start position of the replacement and the length of the replacement. Under the WORD heading, you see the revised text.

The SUBSTRING and OVERLAY statements use the length option differently. For both, the length indicates how much of the target to replace. However, SUBSTRING always inserts the full expression and never pads the expression to match the length. By contrast, the length in OVERLAY determines how much ABL adds to the target, even if ABL must truncate the expression or pad it with spaces. The r-sub-over.p procedure illustrates the differences between these two statements.
/* This procedure illustrates the differences between the SUBSTRING and
OVERLAY statements. */
DEFINE VARIABLE cOriginal AS CHARACTER NO-UNDO INITIAL "OpenEdge".
DEFINE VARIABLE cSubstring AS CHARACTER NO-UNDO.
DEFINE VARIABLE cOverlay AS CHARACTER NO-UNDO.
DEFINE VARIABLE cResults AS CHARACTER NO-UNDO.

/* Default behavior without optional LENGTH. */
ASSIGN
  cSubstring = cOriginal
  SUBSTRING(cSubstring,2) = "***"
  cOverlay = cOriginal
  OVERLAY(cOverlay,2) = "***"
  cResults = "target = ~"OpenEdge~". ~n~n"

  + "If you do not supply a length, SUBSTRING and OVERLAY default as follows:
  ~n~n" + "SUBSTRING(target,2) = ~"***~" yields: " + cSubstring + ". ~n~n"
  + "OVERLAY(target,2) = ~"***~" yields: " + cOverlay + ".".

/* Behavior with zero LENGTH. */
ASSIGN
  cSubstring = cOriginal
  SUBSTRING(cSubstring,2,0) = "***"
  cOverlay = cOriginal
  OVERLAY(cOverlay,2,0) = "***"
  cResults = cResults +~n~n"

  + "For a zero length, SUBSTRING and OVERLAY behave as follows: ~n~n"
  + "SUBSTRING(target,2,0) = ~"***~" yields: " + cSubstring + ". ~n~n"
  + "OVERLAY(target,2,0) = ~"***~" yields: " + cOverlay + ".".

/* Behavior with LENGTH < replacement. */
ASSIGN
  cSubstring = cOriginal
  SUBSTRING(cSubstring,2,1) = "***"
  cOverlay = cOriginal
  OVERLAY(cOverlay,2,1) = "***"
  cResults = cResults +~n~n"

  + "For a length shorter than the replacement, SUBSTRING and OVERLAY behave
  as follows: ~n~n"
  + "SUBSTRING(target,2,1) = ~"***~" yields: "
  + cSubstring + ". ~n~n"
  + "OVERLAY(target,2,1) = ~"***~" yields: "
  + cOverlay + ".".

/* Behavior with LENGTH = replacement. */
ASSIGN
  cSubstring = cOriginal
  SUBSTRING(cSubstring,2,3) = "***"
  cOverlay = cOriginal
  OVERLAY(cOverlay,2,3) = "***"
  cResults = cResults +~n~n"

  + "For a length equal to the replacement, SUBSTRING and OVERLAY behave as
  follows: ~n~n"
  + "SUBSTRING(target,2,3) = ~"***~" yields: "
  + cSubstring + ". ~n~n"
  + "OVERLAY(target,2,3) = ~"***~" yields: "
  + cOverlay + ".".
SUPER function

Runs the super procedure version of the current user-defined function.

This language element must appear within a user-defined function, but can appear anywhere within the user-defined function. If this language element does not appear within a user-defined function, the compiler reports an error.

Syntax

```
SUPER [ ( parameter [ , parameter ] ... ) ]
```

**parameter**

A parameter of the super version of the current user-defined function. These parameters must have the same signature (number of parameters, and type and mode of each) as the parameters of the current user-defined function. You can, however, adjust a parameter’s value.

For the **parameter** syntax, see the Parameter definition syntax reference entry.

If a user-defined function cannot be located in any super procedure, the AVM generates the following error message:

```
SUPER version of user-defined function name invoked but could not be found
```

Errors are stored in the ERROR-STATUS handle when NO-ERROR is specified.

Example

For an example of the SUPER function, see the RUN SUPER statement reference entry.

Notes

- To run the super version of an internal procedure, use the RUN SUPER statement.

Note

- Do not split double-byte characters. This statement allows you to replace either the lead- or trail-byte of the target string when you specify "RAW" for the type parameter.

See also

OVERLAY statement, SUBSTRING function
For the rules that ABL uses to find the super version of the current user-defined function, see the ADD-SUPER-PROCEDURE( ) method reference entry.

See also  ADD-SUPER-PROCEDURE( ) method, REMOVE-SUPER-PROCEDURE( ) method, RUN SUPER statement, SOURCE-PROCEDURE system handle, SUPER-PROCEDURES attribute, TARGET-PROCEDURE system handle

SUPER statement

Invokes a constructor for the immediate super class as the first statement in a constructor of the defining class.

Syntax

```
SUPER ( [ parameter [ , parameter ] . . . ] )
```

Specifies zero or more parameters passed to a PROTECTED or PUBLIC constructor that is defined for the super class. You must provide the parameters identified by the specified constructor, matched with respect to number, data type, and mode. To invoke a constructor that is overloaded in the class, you must specify sufficient information for each parameter to disambiguate it from all other constructors in the class. Otherwise, ABL raises an error identifying the ambiguity.

For information on the parameter passing syntax and disambiguating overloaded constructors, see the Parameter passing syntax reference entry.

Notes

- You can invoke this statement only as the first executable statement in a constructor of a class. If there is no constructor defined in the immediate super class or there is a constructor defined that does not take parameters, you do not need to explicitly invoke this statement in constructors of the defining class. By default, ABL implicitly invokes either the built-in default constructor or any constructor defined in the super class without parameters when the defining class is instantiated. You only need to explicitly invoke a super class constructor if it is defined with parameters.

- If all of the constructors defined for the super class take parameters, the first executable statement of at least one overloaded constructor in the defining class must explicitly invoke a super class constructor.

- Any PUBLIC constructor for a class must either invoke a constructor in the immediate super class (implicitly, or explicitly using the SUPER statement), or it must call another constructor defined in the same class (using the THIS-OBJECT statement). This other constructor must also invoke either a super class constructor or call another constructor defined in the same class. The last constructor in any chain of constructors called in the same class must always call a super class constructor (again, implicitly or explicitly).

See also  CONSTRUCTOR statement, Parameter passing syntax, THIS-OBJECT statement, SUPER system reference
SUPER system reference

A system reference that lets a subclass call the PUBLIC and PROTECTED instance methods of its super class in the inherited class hierarchy. If the specified method definition is not found in the subclass's immediate super class, ABL repeatedly looks to the next super class in the inherited class hierarchy until it finds the definition.

Syntax

```
SUPER:method-name ( [ parameter [, parameter ] . . . ] ) [ NO-ERROR ]
```

*method-name*

Specifies the name of an instance method defined in a super class. The method definition cannot be abstract or ABL raises a compiler error.

( [ parameter [, parameter ] . . . ] )

Specifies zero or more parameters passed to a PROTECTED or PUBLIC method that is defined for the super class. You must provide the parameters identified by the specified method, matched with respect to number, data type, and mode. To invoke a method that is overloaded in the class, you must specify sufficient information for each *parameter* in order to disambiguate it from all the other methods that it overloads. Otherwise, ABL raises an error identifying the ambiguity.

For information on the parameter passing syntax and disambiguating overloaded methods, see the Parameter passing syntax reference entry.

NO-ERROR

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.
- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block **without** a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block **with** a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.
• Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

• NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

• A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

• When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

• If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

Notes

• You typically use the SUPER system reference within a method of a class defined somewhere in the hierarchy to invoke a method defined in a super class that was overridden in a subclass. For more information about using the SUPER system reference, see OpenEdge Development: Object-oriented Programming.

• You cannot use the SUPER system reference to call a static method.

See also

Class-based method call, Parameter passing syntax, SUPER statement

SYSTEM-DIALOG COLOR statement
(Windows only; Graphical interfaces only)

Displays a dialog box that lets the user choose and associate a system color with the specified dynamic color number. The SYSTEM-DIALOG COLOR statement provides a dialog box appropriate to the graphical environment in which it runs.

Note: Does not apply to SpeedScript programming.
SYSTEM-DIALOG COLOR statement

Syntax

```
SYSTEM-DIALOG COLOR color-number
  [ UPDATE logical-variable ]
  [ IN WINDOW window ]
```

`color-number`

An integer expression that evaluates to an ABL color number from 0 to 255, inclusive, that is defined as dynamic through the SET-DYNAMIC method of the COLOR-TABLE handle. The color dialog associates the ABL color specified by `color-number` with the system color value the user selects in the dialog box. The user chooses the OK button to confirm the choice. The user can close the dialog box without changing the color by choosing the Cancel button.

`UPDATE logical-variable`

Specifies a logical variable to return the status of the user’s color dialog interaction. If the user chooses the OK button, the dialog sets `logical-variable` to TRUE. If the user chooses the Cancel button, the dialog sets `logical-variable` to FALSE.

`IN WINDOW window`

Specifies the window where the dialog box is displayed. The value `window` must be the handle of a window.

**Example**

The following procedure displays a dialog box that allows the user to assign new foreground and background colors to the dialog box. A radio set in the dialog box lists selections for foreground and background that correspond to the numbers nine and eight, respectively. Choosing the OK button opens a color dialog box to assign a new system color to the selected color number. Note that the UPDATE option is not used to return a termination status because the dialog does not require the user to select a new color; it only provides the option. The procedure terminates when the user chooses the Cancel button in the radio selection dialog box.
Note that the trigger for the ok-button must assign the curr-color variable to obtain the latest value selected for the radio set. The GET-DYNAMIC and SET-DYNAMIC methods are used to ensure that the color is dynamic before modifying it.

**Notes**

- For more information on defining dynamic colors, see *OpenEdge Deployment: Managing ABL Applications*.
- Use the `color-number` in a COLOR phrase to assign the selected color to a widget.

**See also**

COLOR phrase, COLOR-TABLE system handle

---

**SYSTEM-DIALOG FONT statement**

(Windows only; Graphical interfaces only)

Displays a dialog box that allows the user to select and associate a system font with the specified font number. The SYSTEM-DIALOG FONT statement provides a dialog box appropriate to the graphical environment in which it runs.

**Note:** Does not apply to SpeedScript programming.
SYSTEM-DIALOG FONT statement

Syntax

```
SYSTEM-DIALOG FONT font-number
[ ANSI-ONLY ]
[ FIXED-ONLY ]
[ MAX-SIZE point-size ]
[ MIN-SIZE point-size ]
[ UPDATE logical-variable ]
[ IN WINDOW window ]
```

`font-number`

An integer expression that returns an ABL font number (0 to 255), inclusive, which is defined in the setup file for your environment. The font dialog associates the ABL font specified by `font-number` with the system font the user selects in the dialog. The user confirms the selection and completes the dialog by choosing the OK button. The user interrupts the dialog without changing the font by choosing the Cancel button.

`ANSI-ONLY`

Allows the font dialog to provide only fonts that contain character representations and that do not include graphic symbols.

`FIXED-ONLY`

Allows the font dialog to provide only mono-spaced fonts.

`MAX-SIZE point-size`

Has no effect; supported only for backward compatibility.

`MIN-SIZE point-size`

Has no effect; supported only for backward compatibility.

`UPDATE logical-variable`

Specifies a logical variable to return the status of the user's font dialog interaction. If the user clicks on the OK button, the dialog sets `logical-variable` to TRUE. If the user chooses on the Cancel button, the dialog sets `logical-variable` to FALSE.

`IN WINDOW window`

Specifies the window from which the dialog box is displayed. The value `window` must be the handle of a window.

Example

The following procedure displays a dialog box that allows the user to change the font of either its radio set or its buttons. The radio set lists a font number for each selection: font 1 for the radio set and font 2 for the buttons. Choosing the OK button opens a font dialog to assign a new system font to the font number selected in the radio set. Note that the UPDATE option is not used to return a termination status because the dialog does not require the user to select a new font; it only provides the option. The procedure terminates when the user chooses the Cancel button.
Note: The CHOOSE OF OK event trigger must reference the SCREEN-VALUE attribute of the FontSelect variable to obtain the latest value selected for its radio set. This is because the UPDATE statement has not yet completed during the event, and has not updated the FontSelect record buffer from the frame buffer. The initial value of FontSelect is its value in the record buffer immediately before the UPDATE statement executes.

Notes

- For more information on defining font numbers, see *OpenEdge Deployment: Managing ABL Applications*.
- Use the *font-number* with the FONT option to assign the selected font to a widget.

**SYSTEM-DIALOG GET-DIR statement**  
(Windows only)

Displays a dialog box that allows the user to enter a directory name that is assigned to a character variable. The SYSTEM-DIALOG GET-DIR statement provides a dialog box appropriate to the environment in which it runs.

Note: Does not apply to SpeedScript programming.

**Syntax**

```
SYSTEM-DIALOG GET-DIR character-field
[ INITIAL-DIR directory-string ]
[ RETURN-TO-START-DIR ]
[ TITLE title-string ]
```
**character-field**

The character field or variable that contains the directory name the user enters. The user can enter the directory name by typing it or selecting it from a list of directories in the common dialog directory. The user confirms the entry and completes the dialog by choosing the OK button. The user can interrupt the dialog without any selection by choosing the Cancel button.

**INITIAL-DIR directory-string**

Sets the starting directory for this invocation of SYSTEM-DIALOG GET-DIR to the pathname specified in `directory-string` before starting the dialog. The `directory-string` is a character expression that must evaluate to a valid pathname in your environment. The default starting directory is either the current working directory or the directory left from the last invocation of SYSTEM-DIALOG GET-DIR.

**RETURN-TO-START-DIR**

This option resets the current directory to the starting directory when the common dialog ends. This is the directory specified by the INITIAL-DIR option or the default starting directory.

If you do not specify this option, the directory remains set at the last directory referenced by the user. This directory becomes the default initial directory for subsequent invocations of SYSTEM-DIALOG GET-DIR. This option also has no effect on subsequent invocations that specify the INITIAL-DIR option.

**TITLE title-string**

Specifies a title for the dialog box. The value `title-string` can be any character expression. If you do not specify a title, the dialog uses the system default for your environment.

**Notes**

- The default common dialog directory for the initial invocation of SYSTEM-DIALOG GET-DIR is the current working directory. You can specify a different starting common dialog directory with the INITIAL-DIR option and the user can change the common dialog directory by referencing a different directory in the common dialog.

- The Windows common dialog never searches the `PROPATH`, and always returns the full pathname of the entered relative pathname appended to the current common dialog directory.

**SYSTEM-DIALOG GET-FILE statement**

*Windows only*

Displays a dialog box that allows the user to enter a filename that is assigned to a character variable. The SYSTEM-DIALOG GET-FIILE statement provides a dialog box appropriate to the environment in which it runs.

**Note:** Does not apply to SpeedScript programming.
SYSTEM-DIALOG GET-FILE statement

Syntax

```system-dialect
SYSTEM-DIALOG GET-FILE character-field
  [ FILTERS name filespec
    [ , name filespec ] ...
    [ INITIAL-FILTER filter-num ]
  ]
  [ ASK-OVERWRITE ]
  [ CREATE-TEST-FILE ]
  [ DEFAULT-EXTENSION extension-string ]
  [ INITIAL-DIR directory-string ]
  [ MUST-EXIST ]
  [ RETURN-TO-START-DIR ]
  [ SAVE-AS ]
  [ TITLE title-string ]
  [ USE-FILENAME ]
  [ UPDATE logical-variable ]
  [ IN WINDOW window ]
```

**character-field**

The character field or variable that contains the filename the user enters. The user can enter the filename by typing it or selecting it from a list of files in the common dialog directory. The user confirms the entry and completes the dialog by choosing the OK button. The user can interrupt the dialog without any selection by choosing the Cancel button.

You can also use `character-field` to pass a default filename entry to the dialog. See the USE-FILENAME option for more information.

**FILTERS name filespec**

Defines one or more filters for the filename dialog. Each filter selects a subset of the available files in the common dialog directory to build the dialog file selection-list. A filter consists of two parts: a label (`name`) and file specification (`filespec`).

The `name` is a character expression used as a label for your filter. Windows uses the label to identify the filter in a filter selection-list. The user can select the label to view the list of files selected by the filter.

The `filespec` is a character expression that evaluates to a file specification string. This string can consist of any wild cards or regular expressions used to generate valid file specifications in your environment. In Windows, `filespec` can also consist of multiple file specifications, separating each one with a comma, for example: `*.p,*.i,*.r`.

If you do not specify any filters, the dialog builds the selection-list with all files in the directory.

**INITIAL-FILTER filter-num**

Specifies the initial filter list defined by the FILTERS option, where `filter-num` is an integer expression that evaluates to the position of the filter in the list, starting from 1.

If you do not specify the INITIAL-FILTER option, the dialog uses the first filter in the list as the initial filter.
SYSTEM-DIALOG GET-FILE statement

ASK-OVERWRITE

Causes the dialog to prompt for confirmation if the user enters the name of a file that already exists. By default, the dialog does not prompt for confirmation if the user enters an existing filename. In Windows, this option is ignored unless SAVE-AS is also specified.

CREATE-TEST-FILE

Causes the filename dialog to create a temporary file before it completes in order to verify that the user has write access to the directory path specified for the filename entry. If the dialog cannot write the file, it displays an error message and prompts for another filename entry. The dialog does not complete until the user enters a filename associated with a writable directory or chooses the Cancel button to interrupt the dialog. After successful completion, the dialog deletes the temporary file.

This option is especially appropriate with the SAVE-AS option to verify the ability to save a file.

DEFAULT-EXTENSION  extension-string

Specifies a default extension (or suffix) to be appended to the user’s filename entry after completing the filename dialog, where extension-string is a character expression that evaluates to a valid file extension in your environment, including all required punctuation. In Windows, the extension must start with a period.

The Windows dialog appends the specified extension to the user’s filename entry only if the entry does not already contain an extension.

INITIAL-DIR  directory-string

Sets the starting directory for this invocation of SYSTEM-DIALOG GET-FILE to the pathname specified in directory-string before starting the dialog. The directory-string is a character expression that must evaluate to a valid pathname in your environment. The default starting directory is either the current working directory or the directory left from the last invocation of SYSTEM-DIALOG GET-FILE.

MUST-EXIST

Requires that the user’s filename entry, complete with any specified default extension, must exist in the directory specified for the filename entry before the dialog completes. If it does not exist, the dialog displays an error message and prompts for another filename entry. The dialog does not complete until the user enters the name of an existing file or chooses the Cancel button to interrupt the dialog.

RETURN-TO-START-DIR

This option resets the current directory to the starting directory when the common dialog ends. This is the directory specified by the INITIAL-DIR option or the default starting directory.

If you do not specify this option, the directory remains set at the last directory referenced by the user. This directory becomes the default initial directory for subsequent invocations of SYSTEM-DIALOG GET-FILE. This option also has no effect on subsequent invocations that specify the INITIAL-DIR option.
SAVE-AS

Causes the dialog box to become a Save As dialog box. For a Save As dialog box, the default box title is "Save As". You can use the ASK-OVERWRITE option with SAVE-AS to get confirmation before accepting an existing file from the dialog.

TITLE title-string

Specifies a title for the dialog box. The value title-string can be any character expression. If you do not specify a title, the dialog uses the system default for your environment.

USE-FIELDNAME

Specifies the contents of character-field as the default filename entry for the dialog. During the dialog, the user can accept the default entry or override it by entering or selecting another filename.

UPDATE logical-variable

Specifies a logical variable to return the status of the user’s filename dialog interaction. If the user chooses the OK button, the dialog sets logical-variable to TRUE. If the user chooses the Cancel button, the dialog sets logical-variable to FALSE.

IN WINDOW window

Specifies the window from which the dialog box is displayed. The value window must be the handle of a window.

Example

The following example uses the filename dialog box to run procedures. It allows the user to select and run procedure files until they choose the Cancel button.

r-fildlg.p

```plaintext
DEFINE VARIABLE procname AS CHARACTER NO-UNDO.
DEFINE VARIABLE OKpressed AS LOGICAL NO-UNDO INITIAL TRUE.

Main:
REPEAT:
  SYSTEM-DIALOG GET-FILE procname
  TITLE "Choose Procedure to Run ..."
  FILTERS "Source Files (*.p)"   "*.p",
         "R-code Files (*.r)"   "*.r"
  MUST-EXIST
  USE-FIELDNAME
  UPDATE OKpressed.
  IF OKpressed = TRUE THEN
    RUN VALUE(procname).
  ELSE LEAVE Main.
END.
```

Notes

- The default common dialog directory for the initial invocation of SYSTEM-DIALOG GET-FILE is the current working directory. You can specify a different starting common dialog directory with the INITIAL-DIR option and the user can change the common dialog directory by referencing a different directory in the common dialog.
The Windows common dialog never searches the PROPATH, and always returns the full pathname of the entered relative pathname appended to the current common dialog directory.

**SYSTEM-DIALOG PRINTER-SETUP statement**

(Windows only)

Displays the Windows Print dialog box and lets the user set the default print context for subsequent print jobs in Windows.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```
SYSTEM-DIALOG PRINTER-SETUP
   [ NUM-COPIES expression ]
   [ LANDSCAPE | PORTRAIT ]
   [ UPDATE status ]
   [ IN WINDOW window ]
```

**NUM-COPIES expression**

Specifies the initial value of the Copies field in the Print dialog box. The value expression must evaluate to an integer expression. The user can change this value within the dialog box. This option is supported only with printer drivers that support multi-copy printing. Otherwise, the Copies field is disabled.

**LANDSCAPE**

Specifies the initial value of the Orientation field in the Properties dialog box as landscape. The user can change this value within the dialog box. The Properties dialog box is accessible from the Print dialog box. This option is supported only with printer drivers that support landscape page orientation.

**PORTRAIT**

Specifies the initial value of the Orientation field in the Properties dialog box as portrait. The user can change this value within the dialog box. The Properties dialog box is accessible from the Print dialog box. This option is supported only with printer drivers that support portrait page orientation.

**UPDATE status**

Specifies a logical variable to return the status of the user’s dialog interaction. If the user chooses the OK button, the dialog sets status to TRUE. If the user chooses the Cancel button, the dialog sets status to FALSE.

**IN WINDOW window**

Specifies the window from which the Print dialog box is displayed. The value window must be the handle of a window.
Example

This example presents a dialog box that allows you to set up and print information from the sports database. When you choose the Printer Setup button, it displays the Windows Print dialog box. Using the latest settings, you can then print a list of customer names from the sports database in alphabetical order by choosing the Print Customer Names button.

r-prtdlg.p

```plaintext
DEFINE BUTTON bprintset LABEL "Printer Setup".
DEFINE BUTTON bprintnames LABEL "Print Customer Names".
DEFINE BUTTON bcancel LABEL "Cancel".

DEFINE FRAME PrintFrame
    bprintset bprintnames bcancel
    WITH TITLE "Quick Printer" VIEW-AS DIALOG-BOX.

ON CHOOSE OF bprintset DO:
    SYSTEM-DIALOG PRINTER-SETUP.
END.

ON CHOOSE OF bprintnames DO:
    OUTPUT TO PRINTER.
    FOR EACH Customer NO-LOCK BY Customer.Name:
        DISPLAY Customer.Name WITH STREAM-IO.
    END.
    OUTPUT CLOSE.
END.

ENABLE ALL WITH FRAME PrintFrame.
WAIT-FOR CHOOSE OF bcancel IN FRAME PrintFrame.
```

Notes

• The default print context is the set of values that defines the default printer and setup for that printer in Windows. If there is no default print context, the AVM uses the printer control settings from the current environment.

• Use the PRINTER-NAME attribute of the SESSION system handle to set the printer name in the default print context without user intervention.

• By default, the OUTPUT TO PRINTER statement prints jobs based on the default print context. However, you can use the OUTPUT TO PRINTER statement with its various options to override the default print context for a specific print job.

OUTPUT TO statement, SESSION system handle

SYSTEM-HELP statement
(Windows only)

The SYSTEM-HELP statement calls the Microsoft Windows Help engine to display Windows Help topics, and the HTML Help engine to display HTML Help topics.

Note: Does not apply to SpeedScript programming.
Syntax

```plaintext
SYSTEM-HELP file-string
  [ WINDOW-NAME window-name ]
  
  CONTENTS
  | CONTEXT int-expr
  | HELP-TOPIC string
  | KEY string
  | ALTERNATE-KEY string
  | POSITION X x Y y WIDTH dx HEIGHT dy
  | POSITION MAXIMIZE
  | QUIT
  | SET-CONTENTS int-expr
  | CONTEXT-POPUP int-expr
  | PARTIAL-KEY string
  | MULTIPLE-KEY char TEXT string
  | COMMAND string
  | FINDER
  | FORCE-FILE
  | HELP

file-string

The `file-string` parameter is a character expression that specifies the pathname of a help file. If the file has a `.chm` extension (the extension for compiled Microsoft HTML Help files), the Microsoft HTML Help viewer is launched. If the file has a `.hlp` file extension, the Microsoft Windows Help viewer is launched.

WINDOW-NAME window-name

This option is supported for Windows Help (.hlp files) only.

The `window-name` parameter is a character expression that evaluates to the primary or secondary window name as defined in the [WINDOWS] section of the help project file. If the window name is omitted, or if “main” is specified, the primary help window is used.

CONTENTS

Supported only for backward compatibility.

For HTML Help, this option displays the Microsoft HTML Help viewer with the default topic in the content pane. Use the HELP-TOPIC option to specify the topic to display.

For Windows Help, this option displays the help topic defined as the contents in the [OPTIONS] section of the help project file.

CONTEXT `int-expr`

Displays the help topic that the context number identifies. You define context numbers in the [MAP] section of the help project file.

The `int-expr` parameter is the context number for the help topic.
HELP-TOPIC string

This option is supported for HTML Help (.chm files) only.

Displays a help topic in the content pane of the Microsoft HTML Help viewer.

The string parameter is a character expression that indicates the topic (.htm/.html file) within the compiled Microsoft HTML Help (.chm) file to display.

KEY string

For HTML Help, this option displays the topic matching the string found in the keyword index. Use semicolons in the string parameter to delimit multiple keywords. If no match is found, Microsoft HTML Help displays the help viewer with the Index tab on top.

For Windows Help, this option displays the help topic matching the string found in the index keyword list. If there is more than one match, it displays the first topic containing the keyword. If there is no match or the string is omitted, a message is displayed indicating that the keyword is invalid. The string parameter is a character expression that evaluates to a keyword for the desired help topic.

ALTERNATE-KEY string

This option is supported for HTML Help (.chm files) only. For Windows Help (.hlp files), see the MULTIPLE–KEY option.

Displays a help topic matching the string found in the alternate keyword (Alink) index.

The string parameter is a character expression that evaluates to a keyword in the alternate keyword index.

POSITION X x Y y WIDTH dx HEIGHT dy

Positions an existing (already opened) help window as specified.

The x parameter is an integer expression that specifies the x coordinate for the help window.

The y parameter is an integer expression that specifies the y coordinate for the help window.

The dx parameter is an integer expression that specifies the width of the help window.

The dy parameter is an integer expression that specifies the height of the help window.

POSITION MAXIMIZE

Maximizes an existing (already opened) help window.

QUIT

Informs the help application that help is no longer required. If no other applications are using help, the operating system closes the help application.

SET-CONTENTS int-expr

Supported only for backward compatibility. This option is supported for Windows Help (.hlp files) only.
Dynamically re-maps the contents help topic from what is defined in the [OPTIONS] section of the help project file. When a CONTENTS call is made, the new contents help topic is displayed.

The *int-expr* parameter is the context number for the new contents help topic.

**CONTEXT-POPUP int-expr**

This option is supported for Windows Help (.hlp files) only.

Displays the help topic in a pop-up window that the context number identifies. You define context numbers in the [MAP] section of the help project file. If a non-scrolling region exists in a help topic, only that region displays when you use the CONTEXT-POPUP option to display the topic.

The *int-expr* parameter is the context number for the help topic.

**PARTIAL-KEY string**

This option is supported for Windows Help (.hlp files) only.

Displays the help topic matching the string found in the keyword list. In Windows, if there is more than one match, no match, or if the string is omitted, it displays the Help Topics: Window Help Topics dialog box with the Index tab on top.

The *string* parameter is a character expression that evaluates to a partial key for the desired help topic.

**MULTIPLE-KEY char TEXT string**

This option is supported for Windows Help (.hlp files) only. For HTML Help, see the ALTERNATE-KEY option.

Displays the help topic matching a keyword from an alternate keyword table.

The *char* parameter is a character expression that evaluates to the single character keyword table identifier for the required table.

The *string* parameter is a character expression that evaluates to the keyword that is located in the keyword table.

**COMMAND string**

This option is supported for Windows Help (.hlp files) only.

Executes a help macro.

The *string* parameter is a character expression that evaluates to the help macro to execute.

**FINDER**

This option is supported for Windows Help (.hlp files) only.

Displays the Help Topics: Windows Help Topics dialog box, which contains an Index tab, a Find tab, and optionally a Contents tab, with the most recently used tab displayed on top.

If a Contents tab file (.CNT file) is present when you initially call the Help Topics: Windows Help dialog box, then the Content tab displays on top. However, if a .CNT file is
not present, then the dialog box displays with the Index tab on top; the Contents tab is not available.

**FORCE-FILE**

This option is supported for Windows Help (.hlp files) only.

Ensures that the correct help file is open and displayed.

**HELP**

This option is supported for Windows Help (.hlp files) only.

Displays the contents of the ABL Help-on-Help file. In Windows, HELP displays the Help Topics: Windows Help Topics dialog box.

**Example**

The following example demonstrates several features of the SYSTEM-HELP statement with the Procedure Editor help file (editeng.chm). The user can select a button to demonstrate each of the following SYSTEM-HELP options: CONTEXT, KEY, ALTERNATE-KEY, POSITION, POSITION-MAXIMIZE, and QUIT.

To execute this procedure, first copy the editeng.chm file from DLC\prohelp to your current working directory (by default, C:\OpenEdge\WRK). Then open and run r-syshlpchm.p in the Procedure Editor.
DEFINE VARIABLE helpfile AS CHARACTER NO-UNDO.

DEFINE BUTTON b_context LABEL "CONTEXT Call".

FILE-INFO system handle, SEARCH function
**TERMINAL function**

In Windows, in graphical interfaces, TERMINAL returns WIN3. In Windows, in character interfaces, TERMINAL returns CO80, BW80, or MONO, depending on the monitor type. On UNIX, TERMINAL returns the value of the $TERM environment variable. In batch mode, TERMINAL returns a null string.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```plaintext
TERMINAL
```

**Example**

This one-line procedure displays the type of terminal you are using:

```plaintext
r-term.p
```

```plaintext
MESSAGE "You are currently using a" TERMINAL "terminal.".
```

**See also**

TERMINAL statement

---

**TERMINAL statement**

Changes terminal type during program execution. On UNIX, changes the value of the TERM environment variable.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```plaintext
TERMINAL = termid
```

**termid**

A terminal type string. The `termid` can also be an expression. The AVM returns an error message if `termid` is not defined in the PROTERMCAP file. However, `termid` can be the word TERMINAL. The line TERMINAL=TERMINAL reinitializes the terminal.

**Example**

This procedure changes the terminal screen width from 80 columns to 132 columns, then back again:
### Notes

- **TERMINAL** does not change the physical characteristics of a terminal. You must supply a valid terminal type for the existing terminal state.

- The **TERMINAL** statement reinitializes the function key definitions based on the specified **PROTERMCAP** entry. If you have used ON statements to change function key definitions, the **TERMINAL** statement overrides those changes.

- If a subprocedure uses a frame, the frame is composed with the width that was in effect when the subprocedure was compiled. Changing the width (terminal type) outside the scope of that procedure will not change the frame width inside the procedure unless it is recompiled.

  The following sequence of statements does not work as intended, because `subp.p` is not recompiled before its second execution:

#### r-setrm1.p

```plaintext
TERMINAL = "wy60w".
RUN subp.p.
TERMINAL = "wy60".
RUN subp.p.
DISPLAY "Frame (132) too big for screen (80)" WITH CENTERED.
```

### See also

**TERMINAL function**

---

### THIS-OBJECT statement

A statement that invokes an overloaded constructor as the first statement in another overloaded constructor within the same defining class.

**Syntax**

```plaintext
THIS-OBJECT ( [ parameter [ , parameter ] ... ] )
```
( [ parameter [ , parameter ] ... ] )

Specifies zero or more parameters passed to the specified overloaded constructor. You must match the parameters identified by the called constructor with respect to number, data type, and mode, and you must specify sufficient information for each parameter to disambiguate the specified constructor from all other constructors in the class. Otherwise, ABL raises an error identifying the ambiguity.

For information on the parameter passing syntax and disambiguating overloaded constructors, see the Parameter passing syntax reference entry.

**Note**
If you invoke an overloaded constructor in the defining class using THIS-OBJECT, if the constructor that you invoke does not, itself, invoke another overloaded constructor in the defining class, it must invoke a constructor in the immediate super class, either implicitly or explicitly using the SUPER statement.

**See also**
CONSTRUCTOR statement, Parameter passing syntax, SUPER statement, THIS-OBJECT system reference

### THIS-OBJECT system reference

An object reference to the currently running class instance that you can optionally use to access class members defined within the current class hierarchy.

**Syntax**

```
THIS-OBJECT [ : class-member-reference ]
```

**class-member-reference**

A reference to an instance variable data member, instance property, or instance method defined within the current class hierarchy. Any variable data member cannot be defined as an array (with an EXTENT).

**Example**

The following code fragment shows two instance methods defined within a class, where you must qualify a call to one of them with THIS-OBJECT because its name, Display, is an ABL reserved keyword:

```
CLASS TestClass:
    METHOD VOID Display( ):
        END METHOD.
    METHOD VOID Foo( ):
        THIS-OBJECT:Display( ).
        END METHOD.
    END CLASS.
```
Notes

- You can use THIS-OBJECT without a method call to pass an object reference to the currently running object instance as a parameter, or to return an object reference to itself as a method return value.

- Use of the THIS-OBJECT system reference to call instance methods that are available within the class hierarchy where they are defined is generally optional. However, you must use the THIS-OBJECT system reference to call any instance method whose name is identical to an ABL reserved keyword. The same is true if you are calling an event method on a class-defined or inherited instance event of a class whose name is identical to an ABL reserved keyword. For more information, see the Class-based method call reference entry and the “Class Events Reference” section on page 1953.

- Use of the THIS-OBJECT system reference to access instance variable data members or properties that are available within the class hierarchy where they are defined is optional. However, you must use the THIS-OBJECT system reference to access any such data member or property whose name is identical to an ABL reserved keyword. For more information, see the Class-based data member access and Class-based property access reference entry.

- You cannot use the THIS-OBJECT system reference to access a static class member.

- To invoke other constructors defined within the current class, use the THIS-OBJECT statement.

See also

Class-based method call, THIS-OBJECT statement

TIME function

Returns an INTEGER value representing the time as the number of seconds since midnight. Use this function together with the STRING function to produce the time in hours, minutes, and seconds.

Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME</td>
</tr>
</tbody>
</table>

Examples

In r-time.p, the timeleft variable is set to the result of the TIME function subtracted from the number of seconds in a day. The procedure translates this value into seconds, minutes, and hours.
TIMEZONE function

Returns an INTEGER value representing the time zone offset from Coordinated Universal Time (UTC), in minutes. Use this function together with the STRING function to produce the time in hours, minutes, and seconds.

Note: Coordinated Universal Time (UTC) is the current universal standard for time. Local time zone values are relative to UTC. For example, Eastern Standard Time is UTC–05:00.

Syntax

```
TIMEZONE ( [ datetime-tz-expression | char-expression ] )
```

**datetime-tz-expression**

An expression whose value is a DATETIME-TZ.

**char-expression**

A character expression representing the time zone offset. The format of the expression must be +HH:MM.

---

This DISPLAY statement displays the current time.

**r-time2.p**

```
DISPLAY STRING(TIME,"HH:MM:SS").
```

---

If the TIMEZONE function has no arguments, it returns the client or server machine that serves as the time source for applications running during the ABL session (specified by the TIME-SOURCE attribute).

Example  
Following is an example of using the TIMEZONE function:

```apl
DEFINE VARIABLE v-dt-tz AS DATETIME-TZ NO-UNDO
   INITIAL 2002-05-07T15:03:00Z.
DEFINE VARIABLE v-tz AS INTEGER NO-UNDO.
ASSIGN
   v-tz = TIMEZONE("+08:00") /* v-tz = 480 */
   v-tz = TIMEZONE (v-dt-tz). /* v-tz = -300 */
```

See also  
ADD-INTERVAL function, DATE function, DATE-FORMAT attribute, DATETIME function, DATETIME-TZ function, DAY function, ETIME function, INTERVAL function, ISO-DATE function, MONTH function, MTIME function, NOW function, TIME function, TIME-SOURCE attribute, TODAY function, WEEKDAY function, YEAR function, YEAR-OFFSET attribute

---

### TODAY function

Returns the current system date.

**Syntax**

```
TODAY
```

**Example**

This procedure prints the date in the first line at the top of each page of a report. Instead of using TODAY in the FORM statement, the procedure uses a variable to hold the date. This ensures that the same date appears on all pages of the report, even if this procedure runs through midnight.

```apl
DEFINE VARIABLE rptdate AS DATE NO-UNDO.
OUTPUT TO PRINTER.

rptdate = TODAY.
FORM HEADER rptdate "Customer List" AT 34
   "Page" AT 66 PAGE-NUMBER FORMAT ">>>9" SKIP(2)
   WITH NO-BOX PAGE-TOP.
VIEW.

FOR EACH Customer NO-LOCK:
   DISPLAY Customer.Name AT 1 Customer.Address AT 31
      Customer.City + ", " + " " + Customer.State FORMAT "x(35)" AT 31
      WITH NO-BOX NO-LABELS CENTERED.
END.
```
TO-ROWID function

PAGE-TOP frames are re-evaluated on every new page. Therefore, if you do not use a variable for the date, a different date is displayed on the following page(s) if the report starts before midnight and ends after midnight.

See also ADD-INTERVAL function, DATE function, DATE-FORMAT attribute, DATETIME function, DATETIME-TZ function, DAY function, ETIME function, INTERVAL function, ISO-DATE function, MONTH function, MTIME function, NOW function, TIME function, TIME-SOURCE attribute, TIMEZONE function, WEEKDAY function, YEAR function, YEAR-OFFSET attribute

TO-ROWID function

Converts a string representation of a ROWID to a valid ROWID value.

Syntax

```
TO-ROWID ( rowid-string )
```

rowid-string

A string representation of a ROWID. Since ROWID values are a variable sequence of hexadecimal digits, `rowid-string` must be in the form "0x\text{hex-digits}\"", where `hex-digits` is any string of characters from 0 through 9 and A through F.

Example

The following procedure (`r-torwid.p`) selects Customer Balance and credit information and displays it in a browse. You can select any number of rows to store and display more information on the selected Customers.
Thus, when you choose the bstore button, r-torwid.p stores the ROWID string values of all selected Customer records in a temp-table. When you choose the bdisplay button, it displays the selected Customer Phone information in a DOWN frame by converting each stored ROWID string to a ROWID value and finding the corresponding Customer record. (The example also allows you to add selections and restart by deleting the existing selections.)

```sql
DEFINE VARIABLE hcustb AS HANDLE NO-UNDO.
DEFINE VARIABLE irow AS INTEGER NO-UNDO.

DEFINE QUERY custq FOR Customer FIELDS(CustNum Name Balance CreditLimit).
DEFINE BUFFER cust2 FOR Customer.

DEFINE TEMP-TABLE rowtab FIELD rowchar AS CHARACTER
INDEX rowi IS UNIQUE PRIMARY rowchar ASCENDING.

DEFINE BROWSE custb QUERY custq
Customer.CreditLimit WITH 10 DOWN MULTIPLE.

DEFINE BUTTON bstore LABEL "Store Selections".
DEFINE BUTTON bdisplay LABEL "Display Call Selections".
DEFINE BUTTON bclear LABEL "Clear Storage".

DEFINE FRAME brs-frame custb SKIP bstore bdisplay bclear.
DEFINE FRAME dsp-frame cust2.CustNum cust2.Name cust2.Phone
WITH 5 DOWN SCROLL 1.

ON CHOOSE OF bstore DO:
  DO irow = 1 TO custb:NUM-SELECTED-ROWS:
    IF custb:FETCH-SELECTED-ROW(irow) AND
       NOT CAN-FIND(rowtab WHERE STRING(ROWID(Customer)) = rowchar) THEN DO:
      CREATE rowtab NO-ERROR.
      ASSIGN rowchar = STRING(ROWID(Customer)) NO-ERROR.
    END.
  END.
END.

ON CHOOSE OF bdisplay DO:
  CLEAR FRAME dsp-frame ALL.
  FOR EACH rowtab WITH FRAME dsp-frame:
    FIND cust2 WHERE ROWID(cust2) = TO-ROWID(rowchar).
    DISPLAY cust2.CustNum cust2.Name cust2.Phone.
    DOWN WITH FRAME dsp-frame.
  END.
END.

ON CHOOSE OF bclear DO:
  IF custb:DESELECT-ROWS() THEN
    FOR EACH rowtab:
      DELETE rowtab.
    END.
    FRAME dsp-frame:VISIBLE = FALSE.
  END.

OPEN QUERY custq PRESELECT EACH Customer.
ENABLE ALL WITH FRAME brs-frame.

WAIT-FOR WINDOW-CLOSE OF CURRENT-WINDOW.
```
TRANSACTION function

Note: Although TO-ROWID converts a properly formatted string to a ROWID value, there is no guarantee that this value corresponds to an existing record in your database.

See also: DATE function, DECIMAL function, INTEGER function, ROWID function, STRING function

TRANSACTION function

Returns a LOGICAL value that indicates whether a transaction is currently active.

Syntax

```
TRANSACTION
```

Note: The TRANSACTION function replaces `istrans.p`, which was used in Progress Version 6 and earlier to determine whether a transaction was active.

See also: Transaction object handle

TRANSACTION-MODE AUTOMATIC statement
(AppServer only)

Causes the procedure file that executes this statement to become an automatic transaction initiating procedure. This transaction initiating procedure allows you to control an automatic transaction in the context of an AppServer session.

Note: Does not apply to SpeedScript programming.

Syntax

```
TRANSACTION-MODE AUTOMATIC [ CHAINED ]
```

CHAINED

Tells the AppServer session to automatically create a new transaction every time the current transaction is either committed or rolled back.

Notes

- This statement must appear before any other executable statement in a top-level persistent procedure (transaction initiating procedure) running on the AppServer.

- You can control an automatic transaction by accessing the attributes and methods of the transaction object. You can access these attributes and methods on the transaction handle returned by the TRANSACTION attribute of any AppServer procedure handle.

- An automatic transaction remains open in an AppServer session until:
  
  - The current request service returns control to the client after an AppServer procedure invokes the transaction handle `SET-COMMIT()` method or `SET-ROLLBACK()` method.
The transaction initiating procedure is deleted from the session.

- If you specify the CHAINED option, a transaction is always active in the AppServer session until either the transaction initiating procedure is deleted or the AppServer session terminates.

- If you do not specify the CHAINED option and the transaction initiating procedure is still active, after the current transaction terminates, a client application can start a new transaction by directly calling any remote internal procedure of the transaction initiating procedure. When so executed, this remote internal procedure (which can otherwise be empty) creates a new transaction that you can control using the transaction handle.

- As long as an automatic transaction is open, you can execute any internal procedure of the current transaction initiating procedure from any other procedure running on the AppServer. However, if no automatic transaction is open, only a client application can execute such an internal procedure as a remote procedure call, which then opens an automatic transaction. If an AppServer procedure tries to execute such an internal procedure with no automatic transaction open, the procedure call returns an error.

- If a transaction is open when you delete the transaction initiating procedure, the transaction is committed or rolled back according to the value of the transaction handle DEFAULT-COMMIT attribute.

See also  Transaction object handle

Trigger phrase

Defines triggers on one or more user-interface events for a single user-interface component. Use the Trigger phrase within the statement that defines or creates the associated user-interface component.

Note: Does not apply to SpeedScript programming.

Syntax

```
TRIGGERS:
{ ON event-list [ ANYWHERE ]
  { trigger-block
    | PERSISTENT RUN procedure
      [ IN handle ]
      [ ( input-parameters ) ]
  } } . . .
END [ TRIGGERS ]
```

`event-list`

The event or events with which the trigger block is associated. To specify more than one event, separate them with commas as follows:
The events you can specify depend on the type of the associated widget. See the reference entry for the appropriate widget. For more information on each user interface event that ABL supports, see the “Handle-based Object Events Reference” section on page 1827.

ANYWHERE

Specifies that the trigger is a group trigger. This means that it applies not only to the widget being defined or created, but also is a default to any widget contained within that widget. This allows you to create a default trigger for all widgets in a frame or window. You can override the group trigger by defining a trigger on the same event specifically for the widget (or by defining a group trigger on an intervening widget).

trigger-block

A sequence of ABL statements to be executed when any of the specified events occur. The trigger block must be a single ABL statement or a DO block.

PERSISTENT RUN procedure [ IN handle ] [ ( input-parameters ) ]

Specifies a persistent trigger; that is, a trigger that remains in effect after the current procedure terminates. A persistent trigger must be a procedure specified by procedure. The trigger procedure can take one or more input parameters; it cannot have any output parameters. The parameters are evaluated when the trigger is defined. They are not re-evaluated each time the trigger executes.

If you specify the IN handle option, procedure must be the name of an internal procedure defined in the external procedure specified by handle, where handle is an expression that evaluates to a valid procedure handle. The external procedure must be in scope when you run procedure.

Example

This procedure defines triggers for two buttons:
**Notes**

- If you specify the Trigger phrase in the definition of a user-interface component, the Trigger phrase must be the last option in the component definition.

- If you specify a trigger when you define a widget then that trigger applies to every instance of that widget. For example, in `r-trigp.p`, if you enable the nextcust button in more than one frame, each of those buttons inherits the nextcust trigger.

- The input parameters for a persistent trigger are evaluated when the trigger is attached. (For the Trigger phrase, the trigger is attached when the widget is realized.) This means, for example, that you cannot pass the SELF handle as an input parameter.

- The external procedure specified by `handle` is in scope if it is the current procedure, a procedure on the call stack, or a persistent procedure.

**See also**

CREATE widget statement, DEFINE MENU statement, ON statement

---

**TRIGGER PROCEDURE statement**

Defines a schema trigger.

**Syntax**

```plaintext
TRIGGER PROCEDURE FOR event OF object [ options ]
```

- **event**
  
  The event for which the schema trigger is being defined. The Valid events are CREATE, DELETE, FIND, WRITE, and ASSIGN.
**object**

The object on which the event is defined. If the event is CREATE, DELETE, FIND, or WRITE, the object must be a reference to a database table. If the event is ASSIGN, the object must be a reference to a database field qualified by a table name.

**options**

Optional parts of the trigger header.

Headers for CREATE, DELETE, and FIND triggers take no options. Their syntaxes are as follows:

- TRIGGER PROCEDURE FOR CREATE OF `table`
- TRIGGER PROCEDURE FOR DELETE OF `table`
- TRIGGER PROCEDURE FOR FIND OF `table`

In the header for a WRITE trigger you can optionally include one or two buffer names.

- TRIGGER PROCEDURE FOR WRITE OF `table`
  - [ NEW [ BUFFER ] `buffer-name1` ]
  - [ OLD [ BUFFER ] `buffer-name2` ]

In the header for an ASSIGN trigger, you can optionally specify one or two value holders. You can specify formatting for each as follows:
Example

The following is a WRITE trigger for the Customer table. It uses the OLD BUFFER option so that it can determine whether the CustNum value has changed. If the Customer’s outstanding balance exceeds its Credit Limit, the trigger returns the error condition (in which case the record is not updated).
Notes

- Use the Data Dictionary to associate a trigger procedure with a table or field in the database.

- Some 3GL applications execute schema triggers. Triggers might also be executed in batch mode. Therefore, you should avoid any user-interface interactions within schema trigger procedures.

See also

PROCEDURE statement

TRIM function

Removes leading and trailing white space, or other specified characters, from a CHARACTER or LONGCHAR expression.

Syntax

```
TRIM ( expression [, trim-chars ] )
```
expression

An expression (a constant, field name, variable name, or expression) whose value is a CHARACTER or LONGCHAR. If expression is a case-sensitive variable, the AVM performs a case-sensitive trim. If expression is a LONGCHAR, the result is in the same code page.

trim-chars

A character expression that specifies the characters to trim from expression. If you do not specify trim-chars, the TRIM function removes spaces, tabs, line feeds, and carriage returns.

Examples

The following procedure displays a menu that you can use to display Customer and Order information. The option numbers are displayed with leading spaces. The TRIM function removes the leading white space so the menu selection can be easily evaluated.

r-trim.p

```
DEFINE VARIABLE menu AS CHARACTER NO-UNDO EXTENT 3.
DO WHILE TRUE:
   DISPLAY " 1. Display Customer Data" @ menu[1] SKIP
   " 2. Order Data" @ menu[2] SKIP
   " 3. Exit" @ menu[3] SKIP
   WITH FRAME choices NO-LABELS.
   CHOOSE FIELD menu AUTO-RETURN WITH FRAME choices
   TITLE "Demonstration Menu" CENTERED ROW 10.
   HIDE FRAME choices.
   IF TRIM(FRAME-VALUE) BEGINS "1" THEN RUN r-dblnk.p.
   IF TRIM(FRAME-VALUE) BEGINS "2" THEN RUN r-dblnko.p
   IF TRIM(FRAME-VALUE) BEGINS "3" THEN LEAVE.
END.
```

The following example reads a text file and breaks it into words. It assumes that all words are separated by at least one space character. It uses the TRIM function with one parameter to remove white space from the ends of each input line. It then uses the TRIM function with two parameters to remove any punctuation characters from each word.
TRUNCATE function

Truncates a decimal expression to a specified number of decimal places, returning a decimal value.

Notes

- The TRIM function is double-byte enabled. The specified expression and trim-chars arguments can contain double-byte characters. TRIM does not remove double-byte space characters by default.

- A character string displays with the default format of x(8), unless you specify a format or use a statement such as DISPLAY @ literal.

- You can use the DEBLANK option of the Format phrase to remove leading spaces for fields in the input buffer.

- If expression is a case-sensitive field or variable, then trim-chars is also case sensitive. Otherwise, trim-chars is not case sensitive.

See also

LEFT-TRIM function, RIGHT-TRIM function
Syntax

\[
\text{TRUNCATE ( expression , decimal-places )}
\]

**expression**

A decimal expression that you want to truncate.

**decimal-places**

A non-negative integer expression that indicates the number of decimal places for a truncated expression.

**Example**

This procedure doubles each Customer’s CreditLimit and then truncates that value before rounding it to the nearest $1000:

```plaintext
r-trunc.p

FOR EACH Customer:
    FORM Customer.CustNum Customer.Name Customer.CreditLimit
    new-max LIKE Customer.CreditLimit LABEL "New Credit limit".
    Customer.CreditLimit = TRUNCATE((Customer.CreditLimit * 2) / 1000 ,0) * 1000.
    IF Customer.CreditLimit < 15000 THEN
        Customer.CreditLimit = 15000.
    END.
    DISPLAY Customer.CreditLimit @ new-max.
END.
```

**Note**

You can use the TRUNCATE function to treat division as integer division. For example, \( i = \text{TRUNCATE}(x / y, 0) \).

**See also**

ROUND function

**Type-name syntax**

Specifies the name of an ABL or .NET data type that you can specify as a single instance or as an array of such instances. Thus, an ABL data type can be a built-in primitive type or an array of such primitive types, or it can be a class-based built-in or user-defined object type (such as a class or an interface type) or an ABL array of such object types. A .NET data type can only be a class-based object type (such as a class, structure, enumeration, or interface) or an ABL array of such object types. The EXTENT option, used to define an array of types, is thus counted as part of the array type name.

**Syntax**

```
{ primitive-type-name | object-type-name } [ EXTENT [ constant ] ]
```

**primitive-type-name**

An unquoted string that specifies the name of a built-in ABL primitive type. For information on the supported primitive types and their names, see the Data types reference entry.
object-type-name

Specifies an ABL or .NET object type using the following syntax:

Syntax

```
[ " " ] ABL-object-type [ " " ] |  
[ " " ] dotNET-object-type [ " " ]
```

An ABL object type, where `ABL-object-type` consists of text elements with the following syntax:

Syntax

```
[ package-name . ] class-or-interface-name
```

`package-name`

A period-separated list of text components that, along with `class-or-interface-name`, uniquely identify an ABL class or interface. These text components specify a package that is based on a valid directory pathname, relative to PROPATH, which identifies the location of the file that defines the class or interface. Thus, each text component of `package-name` maps to a directory level in the path, and each slash separator in the path corresponds to a period separating two components.

If specified, the relative path of the class definition file represented by `package-name` must remain constant between compile time and run time. If the class definition file resides directly on PROPATH, the class or interface is not defined in a package and therefore has no `package-name` in its type name.

With the presence of an appropriate USING statement you can also specify an ABL object type that is defined in a package using the `class-or-interface-name` without its qualifying `package-name`. For more information, see the notes for this reference entry.

`class-or-interface-name`

The name of an ABL class or interface. This name must match the name of a class definition file (excluding the `.cls` or `.r` extension) located in the relative path represented by `package-name`, if specified.

This name must begin with an alphabetic character and it cannot contain a period or a space. Also, you cannot name a class or interface using a built-in ABL data type name, such as INTEGER (or Integer). For a list of built-in ABL data type names, see the Data types reference entry.

If the `ABL-object-type` has a `package-name` that contains embedded spaces, you must enclose the entire `ABL-object-type` in quotes (""). Otherwise, quotes are optional.
Note: Do not place a class definition file in a directory whose name contains a period (.) character; ABL interprets the component after the period as another directory level and will therefore not find the referenced class definition file.

[ " " dotNET-object-type " " ]

A .NET object type, where dotNET-object-type consists of text elements with the following syntax:

Syntax

[ namespace . ] dotNET-object-name [ + inner-name ]

namespace

A period-separated list of text components that, along with dotNET-object-name, uniquely identify a .NET type. The components of namespace are defined according to .NET requirements. ABL does not support access to .NET types defined in the default namespace. In other words, you cannot access a .NET type that does not have a namespace defined for it.

However, with the presence of an appropriate USING statement, you can also specify a .NET object type using the dotNET-object-name without its qualifying namespace. For more information, see the notes for this reference entry.

dotNET-object-name

The name of a .NET class (including a structure or enumeration), delegate, interface, or other object type referenced within the .NET namespace specified by namespace.

inner-name

The name of a .NET nested (inner) type defined within the .NET type definition specified by namespace.dotNET-object-name. Thus, inner-name can represent the name of an:

– Inner class defined by the specified .NET class

– Inner enumeration defined by the specified .NET class

– Inner interface defined by the specified .NET interface

Caution: .NET languages normally separate the name of an inner type from the defining type name using a period (.). You must replace this period with a plus sign (+) to reference the inner type name in ABL.

If the name part of the dotNET-object-type contains any embedded spaces, square brackets ([ ]), or angle brackets (<>) you must enclose the entire dotNET-object-type in quotes (" "). Otherwise, quotes are optional.
Type-name syntax

For more information on defining object types in ABL, see the CLASS statement or the INTERFACE statement reference entry, depending on the type of class-based object.

EXTENT \[[ constant ]\]

EXTENT indicates that it is an array of the specified type and constant is an integer value that specifies the number of elements in the array. Without constant, the array is an indeterminate array type.

For more information on defining ABL data elements with primitive or object types, see the DEFINE PARAMETER statement, the DEFINE PROPERTY statement, the DEFINE TEMP-TABLE statement, the DEFINE VARIABLE statement, the DEFINE WORK-TABLE statement, or the Parameter definition syntax reference entry.

Examples

If your PROPATH is "C:/myfiles", and your class definition file name is "C:/myfiles/acme/myObjs/CustObjs.cls", then ABL requires package-name to be "acme.myObjs." and class-or-interface-name to be "CustObjs".

The .NET Button class is in the System.Windows.Forms namespace. Therefore, you reference its qualified (complete) type name like this:

The .NET ControlCollection class is an inner class of System.Windows.Forms.Control. Therefore, you reference its qualified type name like this:

System.Windows.Forms.Control+ControlCollection

The following code fragment defines object references to the .NET type, System.Drawing.Point, and to a one-dimensional .NET array of System.Drawing.Point elements:

```
DEFINE VARIABLE rPoint AS CLASS System.Drawing.Point NO-UNDO.
DEFINE VARIABLE rPointArray AS CLASS "System.Drawing.Point[]" NO-UNDO.
```

Notes

- Both elements of an ABL object type name (package-name and class-or-interface-name) must conform to the case sensitivity requirements of the operating system (e.g., UNIX or Windows). On a case-sensitive OS, only the first reference to the object type name must be case correct. ABL follows this initial letter case for all subsequent references to the type.

- You cannot specify Progress as the first component of package-name for any ABL user-defined class. For example, Progress.Inventory.UpdateInv is an invalid type name for a user-defined class and results in a compiler error.

- You must use a class type name (static type-name syntax) to qualify all references to the following static members of an ABL class:
  - All PUBLIC static members that you reference from outside the defining class context.
– All PUBLIC, PROTECTED, or PRIVATE static methods, properties, events or variable data members that you reference from inside the defining class context whose names are identical to a reserved keyword.

– PUBLIC or PROTECTED static methods that are overridden in the current class definition in order to call the specific method definition in a super class. If you do not use static type-name syntax to call an overridden static method, the method definition at the nearest point in the class hierarchy, starting with the current class, is called.

You must also use equivalent static type-name syntax to reference static members of a class whose names are identical to reserved keywords, as well as from inside the ABL class hierarchy, including when you call event methods on inherited static class events.

For more information on using static type-name syntax, see the appropriate reference entry for the static member: Class-based data member access, Class-based method call, or Class-based property access. Also, for information on calling event methods on a static event, see the “Class Events Reference” section on page 1953.

• ABL allows you to name an ABL class or interface using an ABL reserved keyword, such as Display or DISPLAY. For a list of ABL reserved keywords, see the “Keyword Index” section on page 1971. However, this is not a recommended coding practice, in part because ABL does not fully support the use of static type-name syntax for a class or interface name that is an ABL reserved keyword. This limitation is mitigated if the type name is a fully qualified type name that includes both the package-name and class name.

• Depending on the type definition, the context of the type reference, and the presence of an appropriate USING statement, you can use a qualified or an unqualified class or interface name to reference an ABL object type. A qualified type name is one that includes both a package-name and a class-or-interface-name. An unqualified type name is one that includes class-or-interface-name alone, without a package-name. All qualified type names must be fully qualified, using a complete package-name. ABL does not support partially qualified type names using a partial package-name specification. Without an appropriate USING statement, you can only specify an unqualified type name when the type is defined directly on PROPATH (not in a package). In this case, the unqualified type name is the complete type name for the object type.

Note: For classes with static members, Progress Software Corporation recommends that you either define the class in a package-name and always reference its static members using the fully qualified class type name, or use a naming convention that defines static members with unique names.

• Depending on the presence of an appropriate USING statement, you can use a qualified or unqualified type name to reference a .NET type. A qualified .NET type name is one that includes both a namespace and a dotNET-object-name. An unqualified .NET type name is one that includes dotNET-object-name alone, without its defined namespace. All qualified .NET type names must be fully qualified, using a complete namespace. ABL (unlike .NET languages) does not support partially qualified type names using a partial namespace specification. Without an appropriate USING statement, you cannot specify an unqualified .NET type name, because ABL does not support access to .NET types that are defined in the .NET default namespace.

• You can reference a .NET delegate type only in the context of a DEFINE EVENT statement.
When you specify the type name of a class or interface in its ABL type definition statement (CLASS or INTERFACE statement), and the class file where the type is defined resides in a package directory, you must specify the qualified type name (package-name.class-or-interface-name) for its definition, even with the presence of an appropriate USING statement. You can only specify an unqualified type name (class-or-interface-name alone) in its type definition statement when the class file defining the type resides directly on PROPATH (is not in a package directory).

ABL allows a locally scoped name (for example, a variable, temp-table, buffer name) to be identical to the name of an accessible class. If this is the case, the locally scoped name takes precedence over any static type-name reference to the unqualified class type name, causing a compiler error on any such reference to a static class member. To avoid this error, ensure that no locally scoped names have the same name as the class, and always either use fully qualified type-name syntax to reference the static class member or use naming conventions to guarantee uniqueness for static member names.

Because of the similarity between the syntax of object-type-name references and table buffer and field references (including similarities between syntax type-name references and field attribute references), ABL can encounter ambiguous references among them, resulting in compilation errors. To ensure that ABL always recognizes object-type-name references unambiguously, either define all object type names with at least three period (.) separators (in other words, at least three components in any package-name specification) or use naming conventions to guarantee that object-type-name references and database element references are unique. Otherwise, ABL recognizes all such references as object-type-name references.

For example, suppose that you have a user-defined class type in your PROPATH, Sports2000.Customer.Name, which defines a static property, Label. The reference in the following code fragment would then be ambiguous because ABL cannot distinguish between a reference to this static Label property and a reference to the LABEL attribute on the fill-in widget that is defined for the Name field in the Customer table of the Sports2000 database:

```abl
DEFINE VARIABLE cLabel AS CHARACTER NO-UNDO.
```

**Note:** The .NET class library does not list nested types as members (which they are) of the type that defines them. Instead, it lists each nested type definition immediately following the type that defines it. You can identify .NET nested types in this listing by the period (.) that separates the inner-name of the nested type name from the name of the .NET type that defines it. As shown in this syntax and examples, ABL uses a plus (+) instead of a period (.) to reference the inner-name of a nested type.

To compile ABL references to a .NET type, the type must be defined in either an automatically-loaded .NET assembly or in a .NET assembly that is listed in an OpenEdge® assembly references file named assemblies.xml. This file must be available
either in the working directory or in the directory specified by the Assemblies (-assemblies) startup parameter. You must also deploy this file at run time. For more information on working with assembly references files, see OpenEdge Development: GUI for .NET Programming. OpenEdge also loads the following assemblies automatically if they are not referenced in assemblies.xml:

- **Progress.NetUI.dll** — Assembly where all custom OpenEdge .NET classes and interfaces reside
- **Mscoree.dll** — Assembly where all core Microsoft .NET classes and interfaces reside
- **System.Windows.Forms.dll** — Assembly where all Microsoft form and control classes and interfaces reside
- **System.Drawing.dll** — Assembly where basic Microsoft graphics classes and interfaces reside

The point at which OpenEdge loads any .NET assemblies depends on your application (see the following note on loading the CLR).

- OpenEdge loads the .NET Common Language Runtime (CLR) and all required assemblies for access by ABL if any of the following conditions exists:
  - You use the Preload CLR (-preloadCLR) startup parameter to start the current ABL session, which causes the .NET CLR to load at session startup.
  - The ABL compiler encounters a reference to a qualified object type name, and either that type name matches (or results from a match) to a USING statement containing the FROM ASSEMBLY option or the type cannot be found on PROPATH (meaning that ABL assumes it is a .NET type). This reference can occur on any ABL statement where a type name is used, such as a DEFINE VARIABLE, CAST, static method call, and so on.

  **Note:** An unqualified type name that does not resolve to a qualified type name from a USING statement match is assumed to be the name of an ABL user-defined type, which does not cause the CLR to load.

  - At run tim, the ABL Virtual Machine (AVM) executes a statement using the NEW function (classes) for a .NET object.
  - At run tim, the AVM accesses a static .NET method, property, or data member.
  - At run tim, the AVM accesses the FIRST-FORM attribute or LAST-FORM attribute, or accesses the ACTIVE-FORM system reference.

- When you first reference a .NET type in a procedure or class file (compileable unit), ABL is always case-sensitive when using your reference to identify and search for the type definition. However, for names of .NET class members, including properties, data members, methods, and enumeration members, ABL is case insensitive.
Note: Microsoft recommends that .NET names never be distinguished by letter case, alone. However, if a .NET class does have two class members with names distinguished only by letter case, ABL finds only the first one defined in the class.

- For information on how ABL maps .NET types to ABL primitive types, see the Data types reference entry.

- When creating and accessing .NET arrays in ABL, you must use methods of the .NET System.Array type. ABL also supports automatic mappings between ABL and one-dimensional .NET arrays, allowing supported .NET and ABL arrays to be assigned to each other or passed to each other as routine parameters. For more information, see the Data types reference entry.

- Note that you can specify an ABL array of .NET array objects, which is equivalent to a two-dimensional array. The following example defines an ABL array with 10 elements, each of which can reference a one-dimensional .NET array of System.Drawing.Point objects:

```
DEFINE VARIABLE rPointArray AS CLASS "System.Drawing.Point[]"
EXTENT 10 NO-UNDO.
```

- You can also specify a constructed .NET generic type for dotNET-object-name. ABL supports references to a .NET generic type for all uses of .NET types except to specify a .NET class to inherit or a .NET interface to implement in an ABL class definition. For more information on constructing and using .NET generic types in ABL, see the Data types reference entry.

See also Class-based data member access, Class-based method call, Class-based property access, CLASS statement, Data types, DEFINE VARIABLE statement, INTERFACE statement, NEW function (classes), USING statement

**TYPE-OF function**

Verifies that the class instance to which the specified object reference points is an instance of the specified object type, inherits from the specified super class, or implements the specified interface. If the object reference points to an instance of the specified type, the function returns TRUE. Otherwise, it returns FALSE.

**Syntax**

```
TYPE-OF ( object-reference , object-type-name ).
```

*object-reference*

An object reference to a class instance.

*object-type-name*

Specifies the type name of a class, a super class, or an interface that might be defined, inherited from, or implemented (respectively) by the object referenced by *object-reference*. Specify the object type name using the syntax described in the
UNBOX function

Type-name syntax reference entry. With an appropriate USING statement, you can also specify an unqualified class or interface name alone.

See also Type-name syntax, USING statement

UNBOX function
(Windows only; GUI for .NET only)

Unboxes a .NET System.Object or array object and returns a corresponding ABL primitive or array type.

Syntax

```
UNBOX ( object-reference )
```

**object-reference**

Specifies an object reference to a boxed .NET primitive value (System.Object) or to a one-dimensional .NET array object. For a list of the .NET primitive types that a System.Object can box, see Table 23.

If `object-reference` points to a boxed .NET primitive value, the function returns a value of the ABL primitive type that implicitly maps to the boxed .NET type.

If `object-reference` points to a one-dimensional .NET array object, the function returns a copy of the elements contained by the .NET array as an ABL array. If these elements are .NET mapped object types, the returned ABL array contains elements of the corresponding ABL primitive type. Otherwise, the ABL array contains object reference elements of the actual object type contained by the input .NET array.

Example

The following code creates a .NET DataTable with a single DataRow containing two columns, an integer and a character string, and adds data to the two columns in that row. It then processes the data from the "CustNum" (System.Int32) column to get an indication if its value is even or odd and assigns the result to the ABL INTEGER variable iVal. The Item indexed property that is used to access the data has the data type System.Object. So, to use its value in an expression, you must use the UNBOX function to unbox the underlying .NET mapped data type of the System.Object value. In this case, the referenced System.Object represents a System.Int32 value:
Notes

- You must use the UNBOX function if you want to reference an appropriate System.Object property or method return value in an ABL primitive expression, such as when performing arithmetic operations together with compatible ABL variables, fields, or literal values. Invoke the UNBOX function directly in the expression, passing it the System.Object as input, where you would otherwise reference the System.Object itself.

- For any direct assignment of a .NET object or object array to a compatible ABL primitive value or array, use of the UNBOX function is optional, because ABL automatically unboxes the underlying .NET object or array object type to its matching ABL primitive or array type.

- If you have a variable or field defined as a compatible ABL array type that you provide as an argument to an OUTPUT parameter of a .NET method defined as a .NET array object, ABL automatically unboxes the .NET array object into the ABL array argument. This automatic unboxing does not occur for an ABL method, procedure, or user-defined function passing the same parameters. In this case, you can use a direct assignment from a compatible .NET array object argument or use the UNBOX function to explicitly do the necessary conversion.

See also

BOX function, Data types

UNDERLINE statement

Underlines a field or variable, using the next display line for the underline.

**Note:** Does not apply to SpeedScript programming.
UNDERLINE statement

Syntax

```
UNDERLINE [ STREAM stream | STREAM-HANDLE handle ]
    field ... [ frame-phrase ]
```

STREAM stream

Specifies the name of a stream. If you do not name a stream, the AVM uses the unnamed stream. See the DEFINE STREAM statement reference entry and the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces* for more information on streams.

STREAM-HANDLE handle

Specifies the handle to a stream. If handle it is not a valid handle to a stream, the AVM generates a run-time error. Note that stream handles are not valid for the unnamed streams. See the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces* for more information on streams and stream handles.

field

Represents the name of the field or variable you want to underline.

frame-phrase

Specifies the overall layout and processing properties of a frame. For more information on frame-phrase, see the Frame phrase reference entry.

Example

This procedure produces a report of Customer records, categorized by State. When the last Customer for a certain state has been displayed (determined by the LAST-OF function), the UNDERLINE statement underlines the State field.

```
r-under1.p
FOR EACH Customer NO-LOCK BREAK BY Customer.State WITH USE-TEXT:
END.
```

Notes

- Use The UNDERLINE statement to highlight fields or to underline accumulated values that you calculated using functions other than the automatic aggregate functions supplied with ABL.
- When determining the position within a DOWN frame, the DOWN statement and the UP statement count the line used by an underline.
- Even if the layout of a DOWN frame takes multiple screen lines, the underline takes just one line on the screen.
- For a 1 DOWN frame or single frame, the UNDERLINE does not appear. Instead, the AVM clears the frame.

See also

DEFINE STREAM statement, Frame phrase, Stream object handle
UNDO statement

Backs out all modifications to fields and variables made during the current iteration of a block, and indicates what action to take next.

Syntax

```
UNDO
  [ label1 ]
  [ , LEAVE [ label2 ]
  | , NEXT [ label2 ]
  | , RETRY [ label1 ]
  | , RETURN [ return-value | ERROR [ return-value | error-object-expression ] | NO-APPLY ]
  | , THROW error-object-expression
```

`label1`

The name of the block whose processing you want to undo. If you do not name a block with `label1`, UNDO undoes the processing of the closest transaction or subtransaction block. In determining the closest transaction or subtransaction block, the AVM disregards DO ON ENDKEY blocks that do not have the ON ERROR or TRANSACTION option.

`LEAVE label2`

Indicates that after undoing the processing of a block, the AVM leaves the block you name with `label2`. If you do not name a block with the LEAVE option, the AVM leaves the block that was undone. After leaving a block, the AVM continues on with any remaining processing in a routine.

`NEXT label2`

Indicates that after undoing the processing of a block, the AVM does the next iteration of the block you name with `label2`. If you do not name a block, the AVM does the next iteration of the block that was undone.

`RETRY label1`

Indicates that after undoing the processing of a block, the AVM repeats the same iteration of the block you name with `label1`. If you name a block with `label1`, it must be the name of the block that was undone.

`RETRY` is the default processing if you do not use LEAVE, NEXT, RETRY, or RETURN. When a block is retried, any frames scoped to that block are not advanced or cleared.

`RETURN ...`

Returns to the calling routine, or if there is no calling routine, returns to the OpenEdge Editor. The following table describes various RETURN cases:
You cannot specify ERROR within a user-interface trigger block or a destructor. You can specify the NO-APPLY option only within a user-interface trigger block.

**THROW error-object-expression**

The THROW directive stops the execution of the current block of ABL code, or the current iteration of an ABL iterating block, and raises the error type specified in `error-object-expression`. The value of `error-object-expression` is an error object.

In this example, the THROW directive creates an instance of `Progress.Lang.AppError` using one of the default object constructors:

```
UNDO, THROW NEW Progress.Lang.AppError("Can't find this customer", 550)
```
You can only THROW error objects, and an error object is an object derived from the built-in interface Progress.Lang.Error. It is a compile-time error to THROW an object that is not derived from Progress.Lang.Error.

When the THROW occurs, execution stops, and the specified error is raised. The error should then be handled by the NO-ERROR qualifier, a CATCH block, or by an explicit or implicit ON ERROR phrase.

The following notes describe restrictions on using UNDO, THROW:

- If the action on the UNDO statement is THROW, the UNDO cannot have a [label].
  To do so will result in a compile-time error.

- UNDO, THROW is not allowed in a CATCH block associated with the main block of an object destructor method. You cannot raise or RETURN an error from a destructor. To do so will result in a compile-time error. You can use UNDO, THROW within the code of the destructor itself. In this case, the statement will raise error in the destructor block and be caught by the ON ERROR directive of the destructor block (which can only be UNDO, LEAVE).

- UNDO, THROW is not allowed in a CATCH block of a user interface trigger. The ABL does not you to raise or RETURN error out of a user interface trigger. To do so will result in a compile-time error.

- The UNDO, THROW statement can itself raise error or THROW a Progress.Lang.SysError object if it fails. For example, if the statement cannot find the specified error object. In this case, the SysError will be trapped by the same block that would have trapped the successfully thrown error object.

Examples

The r-undo.p procedure prompts you for the initials of a sales representative. If the initials match those of an existing sales representative, the procedure displays that sales representative’s record. Otherwise, it prompts you to add another sales representative with the initials you supplied. If you enter no, the UNDO statement undoes the work you have done since the start of the REPEAT block and lets you enter another set of initials.

r-undo.p

```
DEFINE VARIABLE ans AS LOGICAL NO-UNDO.
REPEAT FOR SalesRep WITH ROW 7 1 COLUMN 1 DOWN CENTERED ON ENDKEY UNDO, LEAVE:
  FIND SalesRep USING SalesRep.SalesRep NO-ERROR.
  IF NOT AVAILABLE SalesRep THEN DO:
    ans = TRUE.
    MESSAGE "SalesRep record does not exist."
    MESSAGE "Do you want to add a SalesRep?" UPDATE ans.
    IF ans THEN DO:
      CREATE SalesRep.
      END.
      ELSE UNDO, RETRY.
    END.
  ELSE DISPLAY SalesRep.
END.
```

This example shows how the UNDO, THROW statement specifies and populates an error object, and how the CATCH block handles it:
r-undothrow1.p

```abl
FIND Customer 1000 NO-ERROR.
/* Raises error on current block (main block of .p); execution goes to CATCH
below */
IF ERROR-STATUS:ERROR THEN
    MESSAGE Customer.CustNum. /* This code does not execute if FIND fails */
    /* This CATCH is on the main block of r-undothrow1.p */
    CATCH eAppError AS Progress.Lang.AppError:
        MESSAGE eAppError:GetMessage(1) eAppError:GetMessageNum(1).
    END CATCH.
```

**Notes**

- You can also specify UNDO processing for a block by using the ON ERROR and ON ENDKEY phrases with a block statement.

- An UNDO statement that specifies a block that encompasses the current system transaction block has no effect on changes made prior to the start of the system transaction. This includes changes made to variables prior to the beginning of the system transaction.

- If nothing changes during a RETRY of a block, then the RETRY is treated as a NEXT or a LEAVE. This default action provides protection against infinite loops.

- For more information on the UNDO statement, see *OpenEdge Getting Started: ABL Essentials*.

**See also**

ON ENDKEY phrase, ON ERROR phrase, RETRY function, RETURN statement, ROUTINE-LEVEL ON ERROR UNDO, THROW statement

**UNIX statement**

*(UNIX only)*

Runs a program, UNIX command, or UNIX script, or starts a UNIX interactive shell to allow interactive processing of UNIX commands.

**Syntax**

```abl
UNIX
[SILENT]
[ command-token | VALUE ( expression ) ] ...
```

**SILENT**

After processing a UNIX statement, the AVM shell pauses and prompts you to press SPACEBAR to continue. You can use the SILENT option to eliminate this pause. Use this option only if you are sure that the UNIX program, command, or batch file does not generate any output to the screen.

```abl
command-token | VALUE ( expression )
```

One or more command (`command-token`) words and symbols that you want to pass the UNIX operating system to execute. The `VALUE` option generates the command tokens included in `expression`, a character string expression. The specified combination of
command-token and VALUE (expression) options can form any legal combination of commands and command options permitted by UNIX, including programs, built-in commands, and scripts. If you do not use any of these options, the UNIX statement invokes the UNIX shell and remains there until you press CTRL+D or the EOF character set by the UNIX stty command.

**Examples**

On UNIX, procedure r-unix.p starts a shell and in it runs the UNIX “ls” command. In Windows, this procedure starts a command processor and runs the DOS “dir” command in it:

```
r-unix.p
```

```
IF OPSYS = "UNIX" THEN UNIX ls.
ELSE IF OPSYS = "WIN32" THEN DOS dir.
ELSE DISPLAY OPSYS "is an unsupported operating system".
```

In r-unix.p, if you type an L, the AVM runs the DOS dir command or the UNIX ls command. If you enter a procedure name that is stored in the proc variable, the RUN statement then runs the procedure.

```
r-unx.p
```

```
DEFINE VARIABLE proc AS CHARACTER NO-UNDO FORMAT "x(40)".
REPEAT:
  DISPLAY "Enter L to list your files"
    WITH ROW 5 CENTERED FRAME a.
  SET proc LABEL "Enter a valid Procedure Name to run"
    WITH ROW 9 CENTERED FRAME b.
  IF proc = "L" THEN
    IF OPSYS = "UNIX" THEN UNIX ls.
    ELSE IF OPSYS = "WIN32" then DOS dir.
    ELSE display "Operating system" OPSYS "is not supported".
    ELSE DO:
      HIDE FRAME a.
      HIDE FRAME b.
      RUN VALUE(proc).
    END.
  END.
```

**Notes**

- If you are using Windows and you use the UNIX statement in a procedure, that procedure will compile. The procedure will run as long as flow of control does not pass through the UNIX statement.
- This command does not exit to UNIX and return. It creates a shell within ABL to execute the command. Thus, you cannot use the UNIX statement as a substitute for the QUIT statement.
- When you use the UNIX cp command as an ABL statement, ABL assumes that a period (.) indicates the end of the statement. This causes the cp command to display a message stating that it requires two arguments. For example, ABL uses the period as the end of the statement indicator:

```
UNIX cp usr/myfile.
```

To use the period as part of a UNIX command, enclose the command in quotation marks. For example:
UNLOAD statement

(Windows only)

Unloads a set of environment specifications from the current environment, which might be the registry or an initialization file.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```
UNLOAD environment [ NO-ERROR ]
```

**environment**

A character expression that evaluates to the name of an environment that a prior LOAD statement specified.

**NO-ERROR**

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.
- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.
- Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.
Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.
- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.
- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.
- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

Notes

- An application cannot UNLOAD a set of environment specifications until it terminates all windows that use those specifications.
- If you UNLOAD the current environment, the default environment becomes the current environment. To define a new current environment, use the USE statement.
- Use the UNLOAD statement to clean up memory in applications, such as the User Interface Builder, that build and run other applications.

See also

LOAD statement, USE statement

UNSUBSCRIBE statement

Cancels a subscription to an ABL named event. Specifically, the UNSUBSCRIBE statement cancels one or more subscriptions to one or more named events.

Note: ABL named events are completely different from the key function, mouse, widget, and direct manipulation events, which are described in the “Handle-based Object Events Reference” section on page 1827. They are also different from the class events described in the “Class Events Reference” section on page 1953.

Syntax

UNSUBSCRIBE [ PROCEDURE subscriber-handle ]
[ TO ] { event-name | ALL } [ IN publisher-handle ]
PROCEDURE subscriber-handle

A procedure handle representing the subscriber to a named event.

The PROCEDURE option lets one procedure cancel a subscription on behalf of another. For example, if you want procedure A to cancel a subscription on behalf of procedure B, set subscriber-handle to the procedure handle of B.

If the PROCEDURE option does not appear, the AVM assumes that the subscriber is THIS-PROCEDURE, the procedure that contains the UNSUBSCRIBE statement.

event-name

A quoted string or character expression representing the name of a named event.

ALL

Cancels all subscriptions.

IN publisher-handle

A procedure handle representing the publisher of a named event.

If the IN option appears, the AVM cancels subscriptions to named events published by publisher-handle-specifically, either all subscriptions (if the ALL option appears), or only subscriptions to event-name (if event-name appears).

If the IN option does not appear, the AVM cancels subscriptions regardless of the publisher-specifically, either all subscriptions (if the ALL option appears), or only subscriptions to event-name (if event-name appears).

Example

For an example, see the reference entry for the PUBLISH statement.

Notes

- When the AVM executes an UNSUBSCRIBE statement, it cancels a subscription when it finds a match. A match means that the SUBSCRIBE and UNSUBSCRIBE event names match, and that one of the following is true:

  - The subscription was created using SUBSCRIBE IN, cancelled using UNSUBSCRIBE IN, and the publisher and subscriber handles in the SUBSCRIBE and UNSUBSCRIBE statements match.

  - The subscription was created using SUBSCRIBE ANYWHERE, and cancelled using UNSUBSCRIBE without the IN option.

- The AVM executes the UNSUBSCRIBE statement with an implicit NO-ERROR option. That is, if the AVM cannot find a match, it does not report an error. To find out what errors, if any, occurred, use the ERROR-STATUS system handle.

- If you create a subscription using SUBSCRIBE ANYWHERE, you cannot cancel the subscription using UNSUBSCRIBE IN.

See also

PUBLISH statement, PUBLISHED-EVENTS attribute, SUBSCRIBE statement, Unsubscribe( ) event method
UP statement

Positions the cursor on a new line in a down or multi-line frame.

When the block specifying the down frame iterates, the AVM automatically advances one frame line. Use the UP statement if you want to move to a different display line at any time.

For more information on down frames, see the DOWN option of the Frame phrase.

**Note:** Does not apply to SpeedScript programming.

### Syntax

```
UP [ STREAM stream | STREAM-HANDLE handle ] [ expression ] [ frame-phrase ]
```

**STREAM stream**

Specifies the name of a stream. If you do not name a stream, the AVM uses the unnamed stream. See the DEFINE STREAM statement reference entry and the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces* for more information on streams.

**STREAM-HANDLE handle**

Specifies the handle to a stream. If handle it is not a valid handle to a stream, the AVM generates a run-time error. Note that stream handles are not valid for the unnamed streams. See the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces* for more information on streams and stream handles.

**expression**

Represents the number of occurrences of data in the frame that you want to move up. UP is the same as UP 1, except that nothing happens until the next data handling statement affects the screen. Several UP statements in a row with no intervening displays are treated like a single UP 1. UP 0 does nothing. If expression is negative, the result is the same as a DOWN expression.

**frame-phrase**

Specifies the overall layout and processing properties of a frame. For more information on frame-phrase, see the Frame phrase reference entry.

### Example

This procedure starts at the bottom of the screen and displays all the Customer database records. The default frame for the FOR EACH block is a down frame. The DISPLAY statement uses that frame. Therefore, the AVM automatically advances down the screen one line after each iteration. You must use an UP 2 rather than an UP 1 because there is an automatic DOWN 1 performed on the display frame at the end of each iteration of the FOR EACH block.

```
r-up.p

FOR EACH Customer:
  UP 2.
END.
```
Notes

- When a frame is a down frame, the AVM automatically advances to the next frame line on each iteration of the block that it is scoped to, whether or not you use the DOWN statement. If you do not want the AVM to do this automatic advancing, name the frame outside of the current block. For more information on frames, see *OpenEdge Getting Started: ABL Essentials*.

- When the AVM reaches the top frame line and then encounters an UP statement, it clears the frame and starts at the bottom line of the frame. However, if you use SCROLL, the AVM moves everything in the frame down one row.

See also

DEFINE STREAM statement, DOWN statement, Frame phrase, SCROLL statement, Stream object handle

**UPDATE statement**

Displays fields or variables, requests input, and then puts the input data in both the screen buffer and in the specified fields or variables.

The UPDATE statement is a combination of the following statements:

- **DISPLAY** — Moves the values of fields or variables into the screen buffer and displays them (#1 in the figure)

- **PROMPT-FOR** — Prompts the user for data and puts that data into the screen buffer (#2 in the figure)

- **ASSIGN** — Moves data from the screen buffer to the record buffer (#3 in the figure)

**Note:** Does not apply to SpeedScript programming.

**Data movement**

![Data movement diagram]

**Diagram Description:**
- **Database**
- **Record buffer**
- **Screen buffer**
- **User**

1. **Arrow from Database to Record buffer**
2. **Arrow from Screen buffer to User**
3. **Arrow from Record buffer to Screen buffer**
Syntax

```
UPDATE
  [ UNLESS-HIDDEN ]
  [ field [ format-phrase ] [ WHEN expression ]
  | TEXT ( field [ format-phrase ] ... )
  | field = expression
  | constant [ AT n | TO n ]
  | ^
  | SPACE [ ( n ) ]
  | SKIP [ ( n ) ]
  ]
...
  [ GO-ON ( key-label ... )]
  [ frame-phrase ]
  [ editing-phrase ]
  [ NO-ERROR ]
```

```
UPDATE record
  [ EXCEPT field ... ]
  [ frame-phrase ]
  [ NO-ERROR ]
```

**UNLESS-HIDDEN**

Restricts UPDATE to fields whose HIDDEN attribute is FALSE.

**field**

Represents the name of the field or variable whose value you want to display, change, and store in the screen and record buffers.

In array fields, array elements with constant subscripts are handled as any other field. Array fields with no subscripts are expanded as though you entered the implicit elements. See the DISPLAY statement reference entry for information on how array fields with expressions as subscripts are handled.

You can supply values for array elements in the UPDATE statement as follows:

```
UPDATE x[1] = "x".
```

This statement assigns the letter x to the first element of array x. If you do not include an array subscript, the AVM assigns the value to all elements of the array.

```
UPDATE X = "X".
```

This statement assigns the letter x to all elements of the array x.
**format-phrase**

Specifies one or more frame attributes for a field, variable, or expression. For more information on *format-phrase*, see the Format phrase reference entry.

**WHEN expression**

Updates the field only when *expression* has a value of TRUE. The *expression* is a field name, variable name, or expression whose value is logical.

**TEXT**

Defines a group of character fields or variables (including array elements) to use automatic word wrap. The TEXT option works only with character fields that are ABL default FILL-IN widgets (not specified with the FILL-IN NATIVE option). When you insert data in the middle of a TEXT field, the AVM wraps data that follows into the next TEXT field, if necessary. If you delete data from the middle of a TEXT field, the AVM wraps data that follows to the empty area. If you enter more characters than the format for the field allows, the AVM discards the extra characters. The character fields formats must be in the x(n) format. A blank in the first column of a line marks the beginning of a paragraph. Lines within a paragraph are treated as a group and will not wrap into other paragraphs.

Table 64 lists the keys you can use within a TEXT field and their actions.

**Table 64: Key actions in a TEXT() field**

<table>
<thead>
<tr>
<th>Key</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPEND-LINE</td>
<td>Combines the line the cursor is in with the next line.</td>
</tr>
<tr>
<td>BACK-TAB</td>
<td>Moves the cursor to the previous TEXT field.</td>
</tr>
<tr>
<td>BREAK-LINE</td>
<td>Breaks the current line into two lines beginning with the character the cursor is in.</td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Moves the cursor one position to the left and deletes the character at that position. If the cursor is at the beginning of a line, BACKSPACE moves the cursor to the end of the previous line.</td>
</tr>
<tr>
<td>CLEAR</td>
<td>Clears the current field and all fields in the TEXT group that follow.</td>
</tr>
<tr>
<td>DELETE-LINE</td>
<td>Deletes the line the cursor is in.</td>
</tr>
<tr>
<td>NEW-LINE</td>
<td>Inserts a blank line below the line the cursor is in.</td>
</tr>
<tr>
<td>RECALL</td>
<td>Clears fields in the TEXT group and returns initial data values for the group.</td>
</tr>
<tr>
<td>RETURN</td>
<td>In overstrike mode, moves to the next field in the TEXT group on the screen. In insert mode, the line breaks at the cursor and the cursor is positioned at the beginning of the new line.</td>
</tr>
<tr>
<td>TAB</td>
<td>Moves to the field after the TEXT group on the screen. If there is no other field, the cursor moves to the beginning of the TEXT group.</td>
</tr>
</tbody>
</table>
In this procedure, the s-com field is a TEXT field. Run the procedure and enter text in the field to see how the TEXT option works:

```
r-text.p
DEFINE VARIABLE s-com AS CHARACTER NO-UNDO FORMAT "x(40)" EXTENT 5.
FORM
"Shipped :" order.ship-date AT 13 SKIP
"Misc Info :" order.instructions AT 13 SKIP(1)
"Order Comments :" s-com AT 1
WITH FRAME o-com CENTERED NO-LABELS TITLE "Shipping Information".
FOR EACH Customer NO-LOCK, EACH Order OF Customer:
  DISPLAY Customer.CustNum Customer.Name Order.OrderNum Order.OrderDate
  Order.PromiseDate WITH FRAME order-hdr CENTERED.
  UPDATE Order.ShipDate Order.Instructions TEXT(s-com) WITH FRAME o-com.
  s-com = ".
END.
```

**field = expression**

Indicates that the value of field is determined by evaluating the expression rather than having it entered on the screen or from a file. In effect, an assignment statement is embedded in the UPDATE statement.

**constant AT n**

Represents a constant value that you want to display in the frame. The n is the column in which you want to start the display.

**constant TO n**

Represents a constant value that you want to display in the frame. The n is the column in which you want to end the display.

```
^  
```

Tells the AVM to ignore an input field when input is being read from a file. Also, the following statement reads a line from an input file and ignore that line:

```
UPDATE
```

**SPACE \[ ( n ) \]**

Identifies the number (n) of blank spaces to insert after the expression displays. The n can be 0. If the number of spaces you specify is more than the spaces left on the current line of the frame, the AVM starts a new line and discards any extra spaces. If you do not use this option or do not use n, the AVM inserts one space between items in the frame.

**SKIP \[ ( n ) \]**

Identifies the number (n) of blank lines to insert after the expression is displayed. The n can be 0. If you do not use this option, the AVM does not skip a line between expressions unless they do not fit on one line. If you use the SKIP option, but do not specify n or if n is 0, the AVM starts a new line unless it is already at the beginning of a new line.
GO-ON (keylabel . . .)

Tells the AVM to take the GO action when the user presses any of the keys listed. You list keys in addition to keys that perform the GO action by default or because of ON statements. For example, if you want the AVM to execute the GO action when the user presses F1, use the statement GO-ON(F1). If you list more than one key, separate them with spaces, not commas.

Note that the GO-ON option is valid if you specify a list of fields in the UPDATE statement, but is invalid if you specify a record.

frame-phrase

Specifies the layout and processing properties of a frame. For more information on frame-phrase, see the Frame phrase reference entry.

ingoing-phrase

Supported only for backward compatibility.

Identifies processing to take place as each keystroke is entered. This is the syntax for editing-phrase:

[ LABEL : ] EDITING : statement . . . END

For more information on editing-phrase, see the EDITING phrase reference entry.

NO-ERROR

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.
- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.
- Use ERROR-STATUS:GET-MESSAGE(message-num) to retrieve a particular message, where message-num is 1 for the first message.
If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

**record**

Specifies the name of a record buffer. All of the fields in the record are processed as if you updated each of them individually.

To update a record in a table defined for multiple databases, you must qualify the record’s table name with the database name. See the Record phrase reference entry for more information.

**EXCEPT field**

Affects all fields except those fields listed in the EXCEPT phrase; they are omitted from the update list.

**Examples**

The following procedure lets you update the Name, Address, City, State, and Country for each Customer record in the database:

```plaintext
r-updat2.p

FOR EACH Customer:
END.
```

The `r-updat2.p` procedure reads each Customer record and lets you update the Name and CreditLimit fields. The VALIDATE option on the first UPDATE statement ensures that you enter a CreditLimit value that is less than 500000. The HELP option displays a message to that effect.
The second FOR EACH block reads every Order belonging to the Customer, displays the OrderNum field, and lets you update the PromiseDate and ShipDate fields. The VALIDATE option ensures that you enter a ship date value that is after today’s date.

This procedure requests a Customer number and then lets you update information for that Customer record. The frame phrase WITH 1 COLUMN 1 DOWN tells the AVM to display the fields in a single column on the screen (rather than in a row across the screen) and to display only one Customer record on the screen at a time.

**Notes**

- If any *field* is a field in a database record, the UPDATE statement upgrades the record lock condition to EXCLUSIVE-LOCK before updating the record.

- If any *field* is part of a record retrieved with a field list, the UPDATE statement rereads the complete record before updating it. If any *field* is not part of the field list (or related fields) fetched with the record, or if *record* includes such unfetched fields, the AVM raises the ERROR condition before the UPDATE statement accepts input. This is because the UPDATE attempts to display the fields before it rereads the record.

- If an error occurs during UPDATE statement input (for example, the user enters a duplicate index value for a unique index), the AVM retries the data entry part of the statement and does not do the error processing associated with the block that contains the statement.

- The UPDATE statement is **not** equivalent to a combination of the DISPLAY and SET statements.

The previous procedure is approximately equivalent to the following procedure:
If an error occurs during an UPDATE statement, the statement is retried until the error is corrected. If this happens during a SET statement, an entire block is retried.

- If you receive input from a device other than the terminal, and the number of characters read by the UPDATE statement for a particular field or variable exceeds the display format for that field or variable, the AVM returns an error. However, if you are setting a logical field that has a y/n format and the data file contains a value of YES or NO, the AVM converts that value to “y” or “n”.

- If you use a single qualified identifier with the UPDATE statement, the compiler first interprets the reference as dbname.tablename. If the compiler cannot resolve the reference as dbname.tablename, it tries to resolve it as tablename.fieldname.

- When updating fields, you must use table names that are different from field names to avoid ambiguous references. See the Record phrase reference entry for more information.

- The UPDATE statement causes ASSIGN and WRITE events to occur and all related database ASSIGN and WRITE triggers to execute. The ASSIGN triggers execute before the WRITE triggers and after the field is actually updated. The WRITE triggers only execute if the ASSIGN triggers do not return an error. If an ASSIGN trigger fails, the database update is undone. This means that all database changes are backed out. If the UPDATE statement occurs within a transaction, any changes to variables, worktable fields, and temp-table fields are also undone unless the variable or field is defined with the NO-UNDO option. Likewise, if a WRITE trigger fails, the UPDATE statement is undone.

- In Progress Version 7 and above, when you execute UPDATE with a specific or implied GO-ON(keylabel) from a called program, the AVM generates an error message (4123). This is due to an incompatibility in focus. The workaround is to add a VIEW FRAME statement after the call to the subprocedure such that the VIEW FRAME is the first statement executed on return from the called procedure.

See also  ASSIGN statement, DISPLAY statement, EDITING phrase, Format phrase, Frame phrase, PROMPT-FOR statement

USE statement
(Windows only)

Specifies environment defaults that apply to subsequent windows that the application creates. The defaults might reside in the registry or in an initialization file. The defaults can involve colors, fonts, environment variables, etc. You must specify a default in a LOAD statement before you specify it in a USE statement.
Note: Does not apply to SpeedScript programming.

Syntax

USE environment [ NO-ERROR ]

```
environment
```

A CHARACTER expression that evaluates to the name of a current environment. If `environment` is non-null, it must have appeared in a prior LOAD statement. If `environment` is the null string (""), the default environment becomes the current environment.

NO-ERROR

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.

- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block without a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.

- Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where `message-num` is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the
error is not suppressed, but handled with the default error processing for that block type.

- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

**Example**

This procedure loads two files, env1.ini and env2.ini, each of which contains a font definition for font0. The program displays a character string in the ABL default window using the definition for font0 from env1.ini. It then creates a new window and displays the same character string using the definition for font0 from env2.ini. Note that the procedure creates the window after the USE statement.

**r-use.p**

```abl
DEFINE VARIABLE w1 AS CHARACTER NO-UNDO VIEW-AS TEXT FONT 0
  FORMAT "x(34)" INITIAL "This is font 0 in the first window".
DEFINE VARIABLE w2 AS CHARACTER NO-UNDO VIEW-AS TEXT FONT 0
  FORMAT "x(35)" INITIAL "This is font 0 in the second window".
DEFINE VARIABLE new_win AS HANDLE NO-UNDO.
LOAD "env1".
LOAD "env2".
USE "env1".
DISPLAY w1 WITH NO-LABELS WITH FRAME a.
PAUSE.
USE "env2".
CREATE WINDOW new_win.
CURRENT-WINDOW = new_win.
DISPLAY w2 in WINDOW new_win WITH NO-LABELS WITH FRAME b.
PAUSE.
DELETE WIDGET new_win.
```

This procedure depends on the existence of files named env1.ini and env2.ini, each of which contains a font definition for font0. If you run this procedure in your environment, you must create these files.

**Notes**

- The USE statement does not change the DefaultFont or the DefaultFixedFont settings. It uses only the information in the [fonts] and [colors] sections of the new current environment’s initialization file.

- Use this statement with applications (such as the User Interface Builder) that build and run other applications using a unique set of environment specifications.

- An application must use this statement after the LOAD statement and before a new window is created to make the loaded set of environment specifications apply to the new window.
• Subsequent PUT-KEY-VALUE and GET-KEY-VALUE statements apply to the environment made available by the USE statement.

See also GET-KEY-VALUE statement, LOAD statement, PUT-KEY-VALUE statement

USERID function

Returns a character string representing the user ID of the current user.

Syntax

```
USERID [(logical-dbname)]
```

`logical-dbname`

The logical name of the database from which you want to retrieve the user ID. The logical database name must be a character string enclosed in quotes, or a character expression. If you do not specify this argument, the Compiler inserts the name of the database that is connected when the procedure is compiled. If you omit this argument and more than one database is connected, ABL returns a compiler error.

Example

This one-line procedure displays the current user ID for the database with the DICTDB alias:

```
r-userid.p
```

```
DISPLAY USERID("DICTDB") LABEL "You are logged in as" WITH SIDE-LABELS.
```

Notes

• Use the Userid (-U) parameter together with the Password (-P) parameter. The AVM checks the _User table for the user ID supplied with the -U parameter. When it finds that user ID, it compares the password supplied with the -P parameter with the password in the _User table. If the two passwords match, the AVM assigns that user ID to the ABL session.

• When using the USERID function, ABL returns a compiler error under the following conditions:
  – There is no database connected
  – You omit the logical-dbname argument and more than one database is currently connected

• When specifying the logical-dbname argument, you must provide the name of the logical database, not the physical database.

• Every user who enters ABL is given an initial user ID. Table 65 shows how ABL determines a user’s initial user ID on UNIX.
Table 65: Determining a UNIX user ID

<table>
<thead>
<tr>
<th>Are there records in the _User table?</th>
<th>Are the -U and -P startup options supplied?</th>
<th>User ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>YES</td>
<td>Error: -U and -P not allowed unless there are entries in the _User table.</td>
</tr>
<tr>
<td>NO</td>
<td>NO</td>
<td>UNIX user ID.</td>
</tr>
<tr>
<td>YES</td>
<td>NO</td>
<td>”” (blank user ID).</td>
</tr>
<tr>
<td>YES</td>
<td>YES</td>
<td>If the -U userid and -P password match those in the _User table, use that user ID. Otherwise, do not assign a user ID.</td>
</tr>
</tbody>
</table>

Table 66 shows how ABL determines a user’s initial user ID in Windows.

Table 66: Determining a Windows user ID

<table>
<thead>
<tr>
<th>Are there records in the _User table?</th>
<th>Are the -U and -P startup options supplied?</th>
<th>User ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO</td>
<td>YES</td>
<td>Error: -U and -P not allowed unless there are entries in the _User table.</td>
</tr>
<tr>
<td>NO</td>
<td>NO</td>
<td>”” (blank user ID) or operating system user ID if available.</td>
</tr>
<tr>
<td>YES</td>
<td>NO</td>
<td>”” (blank user ID).</td>
</tr>
<tr>
<td>YES</td>
<td>YES</td>
<td>If the -U userid and -P password match those in the _User table, use that user ID. Otherwise, do not assign a user ID.</td>
</tr>
</tbody>
</table>

- After ABL starts running, you can use the SETUSERID function to change the current user ID.
- ABL user IDs are case sensitive.
- See *OpenEdge Development: Programming Interfaces* and *OpenEdge Data Management: Database Administration* for more information on security.

See also CONNECT statement, SETUSERID function
USING statement

Allows you to reference a single specified ABL or .NET object type, or reference all the types in an ABL package or .NET namespace, using their unqualified type names.

Syntax

```plaintext
USING
  \{ object-type-name | \{ package-name | namespace \} .* \}
  [ FROM \{ ASSEMBLY | PROPATH \} ]
```

`object-type-name`

Specifies the qualified type name of a single ABL class or interface, or of a single .NET class, structure, interface, or enumeration. This type name must be the fully qualified type name (including the package or namespace) of an ABL or .NET class or interface type (as described in the Type-name syntax reference entry).

Use this option to identify a single ABL class or interface defined in a package, or a single .NET class, structure, interface, or enumeration defined in a namespace, that you want to reference by its unqualified type name.

```plaintext
\{ package-name | namespace \} .*
```

Specifies an ABL `package-name` that includes ABL classes or interfaces that you want to reference, or a .NET `namespace` that includes .NET classes (including structures and enumerations) or interfaces that you want to reference, where an unqualified class, interface, structure, or enumeration name can replace `'*` to form a valid fully qualified type name.

Use this option to identify all the ABL classes or interfaces defined in a package, or all the .NET classes, structures, interfaces, or enumerations defined in a namespace, for reference by their unqualified type names.

```plaintext
[ FROM \{ ASSEMBLY | PROPATH \} ]
```

Optionally identifies where to locate a given type definition whose type is being referenced using this statement. This identification permits the ABL compiler to focus its search for the type definition depending on whether the USING statement specifies an ABL package-based type or a .NET namespace-based type. When you specify the FROM ASSEMBLY option, ABL assumes that the type is a .NET type and uses the list of .NET assemblies defined in the assembly identification file to search for the type definition. When you specify the FROM PROPATH option, ABL assumes that the type is an ABL type and uses PROPATH to search for the type definition. If you do not specify a FROM option, the search for a type definition first uses PROPATH, then uses the specified list of .NET assemblies. In most cases, the use of an appropriate FROM option improves compile-time performance.

Examples

You can use either one of the following code fragments to reference the class `Acme.BusObjs.Customer` using its unqualified or fully qualified class name:
The ControlCollection class is an inner class of the .NET class System.Windows.Forms.Control. Therefore, you can reference these class types by their unqualified type names like this:

```
USING Acme.BusObjs.*.
DEFINE VARIABLE CustObj AS CLASS Customer.
```

```
USING Acme.BusObjs.Customer.*.
DEFINE VARIABLE CustObj AS CLASS Customer.
```

**Notes**

- When a type name is referenced at compile time, ABL uses the specified USING statements to help validate that the type exists in a specified package or loaded assembly.

- This statement must appear before any other compileable statement (except other USING statements or the ROUTINE-LEVEL ON ERROR UNDO, THROW statement) in a procedure (.p or .w) or class definition (.cls) file. The scope of the statement is the file in which it appears.

- This statement has no effect on the object-type-name that defines the name of a user-defined type in a CLASS or INTERFACE statement. In a CLASS or INTERFACE statement, you must always specify the user-defined type that it defines using the fully qualified object-type-name.

- For both ABL and .NET object types, you can only reference class names for classes, interface names for interfaces (and so on) that are defined in the specified ABL package or .NET namespace. For example, you cannot reference partially qualified class names for classes in packages that are further defined under the specified package. To reference the class names of classes in other packages, even those that appear to be subpackages, you must specify an additional USING statement for each package. For example, given the following class file:

```
C:\Classes\Inventory\Shipping.cls
```

If you specify the USING statement in this code fragment, the class references in the following statements are invalid:

```
USING Classes.*.
DEFINE VARIABLE c1Ref AS Inventory.Shipping. /* Invalid */
c1Ref = NEW Inventory.Shipping(). /* Invalid */
```
The following code fragment is correct:

```abl
USING Classes.Inventory.*.

DEFINE VARIABLE c1Ref AS Shipping.
c1Ref = NEWShipping().

/* 1 */ USING System.Windows.Forms.*.
/* Button is resolved by the first USING statement */
/* 2 */ USING "System.Collections.Generic.List<"Button">".
/* 3 */ USING System.Collections.ObjectModel.*.
/* List and Button are resolved by the first two USING statements */
DEFINE VARIABLE ButtonList AS CLASS "List<Button>" NO-UNDO.
/* "Collection<INTEGER>" is resolved by the third USING statement */
DEFINE VARIABLE intColl AS CLASS "Collection<INTEGER>" NO-UNDO.
/* However, this line does not compile */
DEFINE VARIABLE stringList AS CLASS "List<CHARACTER>" NO-UNDO.
```

- You can also reference the fully qualified type names of any object types identified by this statement. You must sometimes do this to avoid ambiguous class or interface name references.

- When you reference a constructed .NET generic type name with the presence of appropriate USING statements, you can also specify the type parameters in its name, as well as the generic type name, itself, using unqualified type name references. This also works to resolve unqualified type-name references to the type parameters specified in the generic object-type-name of successive USING statements. In addition, ABL resolves unqualified type-name references to all the constructed generic types that can be defined for a given namespace specified in a USING statement. For example:

```abl
/* 1 */ USING System.Windows.Forms.*.
/* Button is resolved by the first USING statement */
/* 2 */ USING "System.Collections.Generic.List<"Button">".
/* 3 */ USING System.Collections.ObjectModel.*.
/* List and Button are resolved by the first two USING statements */
DEFINE VARIABLE ButtonList AS CLASS "List<Button>" NO-UNDO.
/* "Collection<INTEGER>" is resolved by the third USING statement */
DEFINE VARIABLE intColl AS CLASS "Collection<INTEGER>" NO-UNDO.
/* However, this line does not compile */
DEFINE VARIABLE stringList AS CLASS "List<CHARACTER>" NO-UNDO.
```

Note that unlike the previous DEFINE statement, the final DEFINE statement does not compile, because there is no USING statement specified to resolve references to all possible constructions of the defined open generic type, in this case, System.Collections.Generic.List<T>. Also in this example, Button is a class in the System.Windows.Forms namespace and Collection<T> is a generic class in the System.Collections.ObjectModel namespace. For more information on referencing .NET generic types in ABL, see the Data types reference entry.

- ABL does not validate the definition of type names, packages, or namespaces during USING statement compilation. When ABL later encounters an unqualified object type name following the compilation of all USING statements, it validates this type name against each available object-type-name, package-name, and namespace specified by these USING statements to identify and verify the type definition.

- During procedure or class definition file compilation, ABL resolves all unqualified type name references according to the following algorithm:

  a) ABL examines the USING statements in order and, for each statement that specifies a object-type-name, compares the unqualified name with the last node of the object-type-name. If the names are equal, ABL considers this a match and
continues compilation with the current USING statement according to its specified FROM option:

- If FROM ASSEMBLY is specified, ABL searches for `object-type-name` in the loaded assemblies.

- If FROM PROPATH is specified, ABL checks if `object-type-name` specifies a built-in class or interface type, and if not, ABL searches for a corresponding class file according to the `object-type-name` package relative to PROPATH.

- If no FROM option is specified, ABL checks if `object-type-name` specifies built-in class or interface type, and if not, ABL first searches for a corresponding class file according to the `object-type-name` package relative to PROPATH, then searches for `object-type-name` in the loaded assemblies.

b) If ABL has not matched the unqualified type name with a `object-type-name` specified in a USING statement, ABL again examines the USING statements in order. For each USING statement that contains a `package-name.*` or `namespace.*`, ABL replaces the “*” with the unqualified name, creating a `object-type-name`. ABL then continues compilation with the current USING statement according to its FROM option:

- If FROM ASSEMBLY is specified, ABL searches for `object-type-name` in the loaded assemblies.

- If FROM PROPATH is specified, ABL checks if `object-type-name` specifies a built-in class or interface type, and if not, ABL searches for a corresponding class file according to the `object-type-name` package relative to PROPATH.

- If no FROM option is specified, ABL checks if `object-type-name` specifies built-in class or interface type, and if not, ABL first searches for a corresponding class file according to the `object-type-name` package relative to PROPATH, then searches for `object-type-name` in the loaded assemblies.

c) If ABL does not identify a qualified type name from any `object-type-name` derived from a USING statement, it searches for the unqualified type name reference as a complete ABL type name (defined without a `package-name`). Thus, ABL searches for an ABL class file with a filename equal to the unqualified type name directly on PROPATH.

If none of these searches identify a valid type definition, ABL generates a compiler error that the type cannot be found.

See also CLASS statement, INTERFACE statement, Type-name syntax

---

VALID-EVENT function

Verifies whether a specified event is valid for a specified widget. For each type of widget, only certain events are valid. The function returns a value (TRUE/FALSE).

**Note:** Does not apply to SpeedScript programming.
VALID-HANDLE function

Verifies that a handle is valid.

**Syntax**

```
VALID-HANDLE ( handle )
```

handle

An expression that evaluates to a value of type HANDLE. If the handle represents an object that is currently valid, VALID-HANDLE returns TRUE. If the handle is no longer valid (if, for example, some procedure deleted the object), the function returns FALSE.

**Example**

In the following example, the user creates a window dynamically. The WINDOW-CLOSE trigger uses the VALID-HANDLE function to determine whether the window has been created.

---

**Note:** Does not apply to SpeedScript programming.

---

**See also**

LAST-EVENT system handle, LIST-EVENTS function, LIST-QUERY-ATTRS function, LIST-SET-ATTRS function, LIST-WIDGETS function
In the example, the VALID-HANDLE function returns a TRUE value only if the window has been created (that is, mywin does not have the Unknown value (?) and the window has not been deleted. Therefore, the DELETE WIDGET statement executes only if mywin is a valid handle.

**Notes**

- A handle becomes invalid if the associated widget or procedure is deleted or is out of scope.
- This function is useful when walking through a list of widgets or persistent procedures using the PREV-SIBLING or NEXT-SIBLING attributes.
- **VALID-HANDLE(handle:PREV-SIBLING)** is FALSE when you reach the first handle in the list. **VALID-HANDLE(handle:NEXT-SIBLING)** is FALSE when you reach the last handle in the list.
- If a handle is valid, it can still point to an obsolete object. That is, ABL can recycle a previously used handle value to reference a new object instance, leaving previously set handles with the same value pointing to older objects. So you can recognize that seemingly identical handles are actually handle copies that point to different objects, ABL supports the UNIQUE-ID attribute on some types of object handles. For more information, see the UNIQUE-ID attribute reference entry.
- The VALID-HANDLE function supports handles to AppServers, proxy persistent procedures, remote persistent procedures, and COM objects. For more information on AppServers, see *OpenEdge Application Server: Developing AppServer Applications*. For more information on COM objects, see *OpenEdge Development: Programming Interfaces*.

**See also**

CREATE SERVER statement, HANDLE function
**VALID-OBJECT function**

Verifies that an object reference points to a valid ABL or .NET object instance. If the object reference represents an object that is currently valid, the function returns TRUE. If the object reference is no longer valid (for example, it was garbage collected or explicitly deleted), the function returns FALSE.

**Syntax**

```
VALID-OBJECT ( object-reference )
```

*object-reference*

An object reference defined for an ABL or .NET object type. For more information, see the [Class-based object reference](#) reference entry.

**See also**

DELETE OBJECT statement

---

**VALIDATE statement**

Verifies that a record complies with mandatory field and unique index definitions.

**Syntax**

```
VALIDATE record [ NO-ERROR ]
```

*record*

The name of the record you want to validate.

To validate a record in a table defined for multiple databases, you must qualify the record’s table name with the database name. See the [Record phrase](#) reference entry for more information.

**NO-ERROR**

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not done and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be done, depending on the order the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM raised the ERROR condition.
- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM generated error messages. ABL handle methods used in a block **without** a CATCH end block treat errors as warnings and do not raise ERROR, do not set the ERROR-STATUS:ERROR attribute, but do add messages to the
VALIDATE statement

ERROR-STATUS system handle. Therefore, this test is the better test for code using handle methods without CATCH end blocks. ABL handle methods used in a block with a CATCH end block raise ERROR and add messages to the error object generated by the AVM. In this case, the AVM does not update the ERROR-STATUS system handle.

- Use ERROR-STATUS:GET-MESSAGE( message-num ) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, then the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

Example

This procedure prompts for an item number. If an Item with that number is not available, the procedure creates a new Item record and lets you supply some Item information. The VALIDATE statement checks the data you enter against the index and mandatory field criteria for the Item record.

r-valid.p

```plaintext
REPEAT FOR Item:
PROMPT-FOR Item.ItemNum.
FIND Item USING Item.ItemNum NO-ERROR.
IF NOT AVAILABLE Item THEN DO:
    CREATE Item.
    ASSIGN Item.ItemNum.
    UPDATE Item.ItemName Item.Price.
    VALIDATE Item.
END.
ELSE
    DISPLAY Item.ItemName Item.Price.
END.
```
Notes

- Because validation is done automatically, you rarely have to use the VALIDATE statement. The AVM automatically validates a record when a record in the record buffer is replaced by another, a record’s scope iterates or ends, the innermost iterating subtransaction block that creates a record iterates, or a transaction ends.

- The AVM automatically validates mandatory fields when those fields are modified.

- If the validation fails on a newly-created record, VALIDATE raises the ERROR condition.

- The AVM performs validation when it leaves a field.

- For complex validations, it might be easier to use the IF...THEN...ELSE statement instead of the VALIDATE statement.

- You cannot use the VALIDATE statement to test fields that are referenced in SQL statements, since validation is not performed for these fields.

- If a field or table has been modified, the VALIDATE statement causes WRITE events and all related WRITE triggers to execute.

See also

IF...THEN...ELSE statement

VIEW statement

Displays a widget (sets its VISIBLE attribute to TRUE).

Note: Does not apply to SpeedScript programming.

Syntax

```
VIEW [ STREAM stream ] [ STREAM-HANDLE handle ] [ widget-phrase ] [ IN WINDOW window ]
```

STREAM stream

Specifies the name of a stream. If you do not name a stream, the AVM uses the unnamed stream.

STREAM-HANDLE handle

Specifies the handle to a stream. If handle it is not a valid handle to a stream, the AVM generates a run-time error. Note that stream handles are not valid for the unnamed streams. See the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces* for more information on streams and stream handles.

widget-phrase

Specifies the widget you want to view. You can view windows, frames, and field-level widgets. You cannot view menus. If you do not use this option, VIEW sets the VISIBLE attribute for the default frame for the current block.
IN WINDOW window

Specifies the window in which to view the widget.

Example

The r-view2.p procedure displays information on a sales representative and then displays all the Customers belonging to that sales representative. Each new sales representative is displayed on a new page. In addition, if the information for a sales representative takes up more than one page, a separate FORM statement describes a continuation header for that sales representative. The VIEW statement for the PAGE-TOP frame hdr2, activates the header for subsequent page breaks.

r-view2.p

```r
OUTPUT TO slsrep PAGED PAGE-SIZE 10.
FOR EACH SalesRep NO-LOCK:
    PAGE.
    FORM HEADER "Sales rep report" "Page" AT 60 PAGE-NUMBER FORMAT ">>>9".
        WITH NO-LABELS.
    FORM HEADER "Sales rep report" SalesRep.SalesRep "(continued)"
        "Page" AT 60 PAGE-NUMBER FORMAT ">>>9" SKIP(1)
        WITH FRAME hdr2 PAGE-TOP.
    VIEW FRAME hdr2.
    FOR EACH Customer OF SalesRep NO-LOCK:
            Customer.State.
    END.
END.
```

Notes

- If the widget is already visible, the VIEW statement has no effect.
- Viewing a widget does not, by itself, show any of its data. To view data in a widget, you must use a data display statement (such as DISPLAY) or assign the data directly to the widget’s SCREEN-VALUE attribute.
- When you view a window, its frames and their descendant widgets are not displayed, unless you explicitly view or display them.
- When you view a widget, the AVM displays that widget unless its parent window or an ancestor window has its HIDDEN attribute set to TRUE.
- When you view a widget that has its HIDDEN attribute set to TRUE, the AVM sets the widget’s HIDDEN attribute to FALSE.
- When you view a widget contained by a window that is invisible (VISIBLE attribute is FALSE), that widget and the containing window is displayed unless the containing window’s HIDDEN attribute is set to TRUE.
- When you view a widget contained by one or more ancestor frames that are invisible, the VISIBLE attribute is set to TRUE and the HIDDEN attribute is set to FALSE for both the viewed widget and all its ancestor frames. However, if the containing window or an ancestor window has its HIDDEN attribute set to TRUE, neither the viewed widget nor its ancestor frames are displayed.
• When you view a frame, that frame and all widgets contained within it are displayed except those widgets whose HIDDEN attributes are set to TRUE.

• When you view a window, the AVM displays that window and any ancestor windows only if no ancestor window has its HIDDEN attribute set to TRUE. If the AVM displays the window, it also views any descendant windows down to, but not including, the first descendent window that has its HIDDEN attribute set to TRUE.

• If you are displaying a root frame and there is not enough room in the window for the new root frame to display, the AVM removes other root frames, starting from the bottom of the window, until there is room for the new root frame.

• In the case of a PAGE-TOP or PAGE-BOTTOM frame, the VIEW statement activates the frame for display at the beginning or end of each page.

See also DEFINE STREAM statement, HIDE statement, Widget phrase, Stream object handle

VIEW-AS phrase

Defines a compile-time defined (static) widget to represent a field or variable on the screen.

Note: Does not apply to SpeedScript programming.

Syntax

```plaintext
VIEW-AS
{  combo-box-phrase
   |  editor-phrase
   |  FILL-IN
      [  NATIVE ]
      [  size-phrase ]
      [  TOOLTIP tooltip ]
   |  radio-set-phrase
   |  selection-list-phrase
   |  slider-phrase
   |  TEXT
      [  size-phrase ]
      [  TOOLTIP tooltip ]
   |  TOGGLE-BOX
      [  size-phrase ]
      [  TOOLTIP tooltip ]
 }
```

Use the following syntax to specify the type of widget to use for displaying values in a browse column:

```plaintext
VIEW-AS combo-box-phrase | TOGGLE-BOX
```
**combo-box-phrase**

Specifies that a field or variable is viewed as a combo box widget. You can use a combo box to represent a value of any data type. This is the syntax for *combo-box-phrase*:

**Syntax**

```
VIEW-AS COMBO-BOX
    [ LIST-ITEMS item-list ]
    [ LIST-ITEM-PAIRS item-pair-list ]
    [ INNER-LINES lines ]
    [ size-phrase ]
    [ SORT ]
    [ TOOLTIP tooltip ]
    [ SIMPLE | DROP-DOWN | DROP-DOWN-LIST ]
    [ MAX-CHARS characters ]
    [ AUTO-COMPLETION [ UNIQUE-MATCH ] ]
```

Use the following syntax to specify a combo-box widget for displaying values in a browse column:

**Syntax**

```
COMBO-BOX
    [ LIST-ITEMS item-list ]
    [ LIST-ITEM-PAIRS item-pair-list ]
    [ INNER-LINES lines ]
    [ DROP-DOWN | DROP-DOWN-LIST ]
    [ MAX-CHARS characters ]
    [ AUTO-COMPLETION [ UNIQUE-MATCH ] ]
```

For more information, see the COMBO-BOX phrase reference entry.

**editor-phrase**

Specifies that a CHARACTER or LONGCHAR field or variable is viewed as a text editor widget. A text editor widget supports cut, paste, word-wrap, and auto-indent features. This is the syntax for *editor-phrase*:

**Syntax**

```
EDITOR
    { size-phrase
        | INNER-CHARS char INNER-LINES lines
    }
    [ BUFFER-CHARS chars ]
    [ BUFFER-LINES lines ]
    [ LARGE ]
    [ MAX-CHARS characters ]
    [ NO-BOX ]
    [ NO-WORD-WRAP ]
    [ SCROLLBAR-HORIZONTAL ]
    [ SCROLLBAR-VERTICAL ]
    [ TOOLTIP tooltip ]
```
For more information, see the EDITOR phrase reference entry.

FILL-IN [ NATIVE ] [ size-phrase ]

Specifies that the field or variable is viewed as a fill-in widget. In a fill-in field, the literal value of the field or variable is displayed. On update, the user types the literal value into the fill-in field.

You can specify FILL-IN for any CHARACTER, INT64, INTEGER, DECIMAL, DATE, DATETIME, DATETIME-TZ, or LOGICAL value (with or without extents). FILL-IN is the default representation for those values.

Note that Windows allows a user to transfer focus to the fill-in field by pressing ALT and one of the letters in the label. For more information on specifying a label using the LABEL option, see the Format phrase reference entry.

If you specify NATIVE, then the field behaves like a native fill-in field under the current user interface. A non-NATIVE field behaves like a default ABL fill-in field under any interface. Native fill-in fields provide better consistency with other applications in graphical environments, but do not support some ABL constructs such as the UPDATE statement with the TEXT option or the CHOOSE statement.

When a non-NATIVE (ABL) fill-in is disabled, the border disappears, but the text does not gray out. When a NATIVE fill-in is disabled, the text grays out.

Like the other static widgets that can be defined using the VIEW-AS phrase, you can specify ToolTips for the fill-in widget using the TOOLTIP option.

radio-set-phrase

Specifies that the field or variable is viewed as a radio set widget. A radio button set is a series of buttons, of which only one can be TRUE at a time. When the user sets one of the buttons to TRUE, the others are set to FALSE. You can specify a radio-set-phrase for any group of CHARACTER, INT64, INTEGER, DECIMAL, DATE, or LOGICAL values (with or without extents). This is the syntax for radio-set-phrase:

Syntax

```
RADIO-SET
[ HORIZONTAL [ EXPAND ] ] | VERTICAL ]
[size-phrase ]
RADIO-BUTTONS label , value [ , label , value ... ]
[ TOOLTIP tooltip ]
```

**Note:** If two or more buttons of a radio set use the same label, the AVM uses only the value of the first button.

For more information, see the RADIO-SET phrase reference entry.

selection-list-phrase

Specifies that the field or variable is viewed as a selection list widget. You can only specify the selection-list-phrase for a character-string value. A selection list is a scrollable list
of CHARACTER values. If the field is enabled for input, the user can select one or more values from the list. This is the syntax for selection-list-phrase:

**Syntax**

```
SELECTION-LIST
[ SINGLE | MULTIPLE ]
[ NO-DRAG ]
[ LIST-ITEMS item-list ]
[ SCROLLBAR-HORIZONTAL ]
[ SCROLLBAR-VERTICAL ]
{ size-phrase | INNER-CHARS cols INNER-LINES rows }
[ SORT ]
[ TOOLTIP tooltip ]
```

For more information, see the SELECTION-LIST phrase reference entry.

**slider-phrase**

Specifies that the field or variable is viewed as a slider. Specify the slider-phrase for an integer value only. A slider is a graphical representation of a numeric range. It is composed of a rectangular area that contains a trackbar. You can change the current value within a defined range by moving the pointer that resides on the trackbar. This is the syntax for slider-phrase:

**Syntax**

```
VIEW-AS SLIDER
MAX-VALUE max-value MIN-VALUE min-value
[ HORIZONTAL | VERTICAL ]
[ NO-CURRENT-VALUE ]
[ LARGE-TO-SMALL ]
[ TIC-MARKS
{ NONE | TOP | BOTTOM | LEFT | RIGHT | BOTH }
[ FREQUENCY n ]
]
[ TOOLTIP tooltip ]
{ size-phrase }
```

For more information, see the SLIDER phrase reference entry.

**TEXT [ size-phrase ]**

Specifies that the field or variable is viewed as read-only text. In a graphical environment, a text field takes up less space on the screen than a native fill-in field.

You can specify TEXT for any CHARACTER, INT64, INTEGER, DECIMAL, DATE, or LOGICAL value (with or without extents).

**TOGGLE-BOX [ size-phrase ]**

Specifies that the field or variable is viewed as a toggle box widget. A toggle box is a small box that is either marked or not marked to indicate a TRUE or FALSE value, respectively.
You can specify TOGGLE-BOX for any LOGICAL value, or any calculated value whose expression evaluates to a LOGICAL value.

Note that Windows allows a user to select a toggle-box item by pressing ALT and one of the letters in the side label. For more information on specifying a label using the LABEL option, see the Format phrase reference entry.

For toggle-box browse columns, the toggle-box always appears whether it is enabled or not. A solid outline appears to indicate that a cell in a toggle-box column currently has focus. The toggle-box is always centered within the column. You cannot specify size-phrase for toggle-box browse columns.

TOOLTIP tooltip

Allows you to define a help text message for a toggle box. The AVM automatically displays this text when the user pauses the mouse over the toggle-box.

You can add or change the TOOLTIP option at any time. If TOOLTIP is set to "" or the Unknown value (?), then the ToolTip is removed. No ToolTip is the default. The TOOLTIP option is supported in Windows only.

**Example**

The following procedure defines a character variable and views it in succession as a text widget, a fill-in widget, an editor widget, and finally as a text widget again. The procedure shows that you can represent a character variable in several ways, as long as each representation appears in a separate frame.

```
r-viewsas.p

DEFINE VARIABLE test AS CHARACTER NO-UNDO INITIAL "Now is the time"
   FORMAT "x(30)".

DISPLAY test VIEW-AS TEXT LABEL "Labels cannot be changed"
   WITH FRAME a SIDE-LABELS.
PAUSE.

UPDATE test VIEW-AS FILL-IN LABEL "But fillins can, please enter a new value"
   WITH FRAME b SIDE-LABELS.

UPDATE test VIEW-AS EDITOR INNER-CHARS 16 INNER-LINES 2 MAX-CHARS 70
   LABEL "As can editors, please enter a new value:",
   WITH FRAME c.

DISPLAY test VIEW-AS TEXT FORMAT "x(70)" LABEL "The final value is:"
   WITH FRAME d.
```

For additional examples, see the COMBO-BOX phrase, EDITOR phrase, RADIO-SET phrase, SELECTION-LIST phrase, and SLIDER phrase reference entries.

**Notes**

- To create a static widget, you must define a static frame that contains the widget. Each frame you define that contains the widget creates an additional instance of that widget for the underlying field or variable. The handle for a static widget is not available until the widget is created.

- You can also use the VIEW-AS option in the Frame phrase and MESSAGE statement to indicate a dialog box and alert box, respectively.

- In Windows, if no font is specified for a fill-in field, ABL uses two default fonts:
WAIT-FOR statement (ABL only)

- A fixed font for date fields, numeric fields, and character fields that contain fill characters (such as the parentheses surrounding the area code of a telephone number).

- A proportional font for character fields that do not contain fill characters.

The AVM looks for these fonts in the current environment, which may be the registry (Windows only) or an initialization file. If the current environment does not define these fonts, the AVM uses the system default fixed and proportional fonts. For more information on environments, see *OpenEdge Deployment: Managing ABL Applications*.

See also  COMBO-BOX phrase, EDITOR phrase, RADIO-SET phrase, SELECTION-LIST phrase, SIZE phrase, SLIDER phrase

WAIT-FOR statement (ABL only)

This WAIT-FOR statement instructs the AVM to stop executing the current block until a specific ABL event occurs. The AVM continues to respond to all other incoming events and execute any associated triggers or event procedures while in this wait state.

**Note:** ABL supports a separate version of the WAIT-FOR statement (.NET WAIT-FOR) that blocks for .NET, as well as ABL, events. For more information, see the WAIT-FOR statement (.NET and ABL) reference entry.

**Syntax**

```
WAIT-FOR event-list OF widget-list
[ OR event-list OF widget-list ] ...
[ FOCUS widget ]
[ PAUSE n ]
```

```
WAIT-FOR "WEB-NOTIFY" OF DEFAULT-WINDOW
[ PAUSE n ]
[ EXCLUSIVE-WEB-USER ]
```

**event-list**

A space or comma-separated list of user-interface events and other ABL events to wait for.

An event can be any event described in the “Handle-based Object Events Reference” section on page 1827.

**widget-list**

A space- or comma-separated list of widgets with which the event is associated. For more information on referencing widgets, see the Widget phrase reference entry.
FOCUS widget

Specifies the widget that initially receives input focus when the WAIT-FOR statement is executed. The value widget must be a valid reference to a widget (a widget name or handle) that is currently displayed and enabled.

PAUSE n

Specifies a time-out interval for the WAIT-FOR statement. The value n can be any numeric expression. If a period of n seconds elapses between events, the WAIT-FOR automatically terminates.

Examples

This procedure defines two buttons, defines triggers for them, and enables them. The procedure then waits for the user to close the current window. The initial focus is placed on the button labeled MORE. The user can then choose buttons continuously until closing the window or exiting with the END-ERROR key.

r-wait.p

```abl
DEFINE BUTTON more-button LABEL "MORE".
DEFINE BUTTON next-button LABEL "NEXT".
FORM Customer.CustNum Customer.Name more-button next-button
   WITH FRAME brief.
FORM Customer EXCEPT Customer.CustNum Customer.Name
   WITH FRAME full.
ON CHOOSE OF more-button
   DISPLAY Customer EXCEPT Customer.CustNum Customer.Name WITH FRAME full.
ON CHOOSE OF next-button DO:
   HIDE FRAME full.
   FIND NEXT Customer NO-LOCK NO-ERROR.
   IF AVAILABLE Customer THEN
     DISPLAY Customer.CustNum Customer.Name WITH FRAME brief.
   END.
FIND FIRST Customer NO-LOCK.
DISPLAY Customer.CustNum Customer.Name WITH FRAME brief.
ENABLE more-button next-button WITH FRAME brief.
WAIT-FOR WINDOW-CLOSE OF CURRENT-WINDOW FOCUS more-button.
```

If the user closes the current window then execution continues after the WAIT-FOR statement. In this case, the procedure ends because there are no more statements.

The following procedure uses the PAUSE option of the WAIT-FOR statement so that you automatically jump ahead to the next record if the user does not perform any action within three seconds after the customer information is displayed:
In this example, the code for finding the next Customer has been moved to an internal procedure. The WAIT-FOR statement has been placed inside a DO loop. The loop iterates when the user chooses the NEXT button or three seconds elapse. (If the user closes the window, the QUIT statement is executed and the loop does not iterate.) On each iteration, if the variable jump-ahead is TRUE, then the next-cust procedure is run to find and display the next Customer. If the user chooses the MORE button for a Customer, jump-ahead is set to FALSE. This prevents the procedure from automatically jumping ahead to the next Customer. Instead, the user can spend time examining the data. To move ahead to the next Customer, the user must explicitly choose the NEXT button. At that point, jump-ahead is reset to TRUE.

**Notes**

- Any widget associated with an event must be enabled before you wait on it.

- In general, do not use an UPDATE statement in an application that executes a WAIT-FOR statement. One exception is updating fields in a dialog box.

- In general, if you nest two WAIT-FOR statements in a single ABL application (where the nested WAIT-FOR executes in a trigger), you must ensure that your application satisfies the nested WAIT-FOR first. The event that satisfies the outer WAIT-FOR statement should be the terminating event for your application.
• In general, when a modal dialog box is active, the event-list can reference only events supported by the active dialog box and the widgets it contains. There are two exceptions:
  – You can specify an event on a procedure handle as long as widget-list specifies only a single procedure handle.
  – You can specify the PROCEDURE-COMPLETE event on an asynchronous request handle.

• In batch mode (running with the -b startup parameter), the WAIT-FOR statement supports only the following events:
  – PROCEDURE-COMPLETE
  – READ-RESPONSE
  – CONNECT
  – Developer events (U1 to U10, and CLOSE)

• The PROCEDURE-COMPLETE event occurs for an asynchronous request handle when the current ABL session receives the response message from the AppServer that executed the request. When the WAIT-FOR statement executes, it processes any PROCEDURE-COMPLETE event that has occurred but has not yet been processed.

• PROCEDURE-COMPLETE events from a single AppServer connection are processed in the order that the associated asynchronous requests were originally generated. To ensure that all pending PROCEDURE-COMPLETE events are handled by a single WAIT-FOR statement, specify a single PROCEDURE-COMPLETE event for the last asynchronous request handle generated before the WAIT-FOR statement.

• To process a PROCEDURE-COMPLETE event for a particular asynchronous request handle, the AVM:
  – Decrements the ASYNC-REQUEST-COUNT attribute for the server referenced by SERVER attribute for the asynchronous request handle.
  – Decrements the ASYNC-REQUEST-COUNT attribute for a persistent procedure, if the PERSISTENT-PROCEDURE attribute of the asynchronous request handle refers to a valid persistent procedure.
  – Sets the COMPLETE attribute for the asynchronous request handle to TRUE.
  – Sets the STOP, QUIT, and ERROR attributes for the asynchronous request handle appropriately as indicated by the response message from the AppServer.
  – Sets the return value for the RETURN-VALUE function, if a return value was returned by the AppServer.
  – Stores any error information returned from the AppServer in the ERROR-STATUS system handle.
  – Attempts to execute the event procedure specified by the EVENT-PROCEDURE and the EVENT-PROCEDURE-CONTEXT attributes for the asynchronous request handle, if EVENT-PROCEDURE is not the empty string (""").
– Sets each INPUT parameter for the event procedure to the Unknown value (?) or, if the parameter is a TEMP-TABLE, the TEMP-TABLE remains unchanged, if the response message indicates that the remote request finished with a STOP, ERROR, or QUIT condition.

– Sets the INPUT parameter values for the event procedure to the OUTPUT and INPUT-OUTPUT parameter values returned by the remote procedure, if the response message indicates that the remote request completed successfully.

– Displays an error message, if a specified event procedure fails to execute for any reason.

– Raises any unhandled STOP condition, ERROR condition, or QUIT condition in the context of the WAIT-FOR statement, if the event procedure completes execution with that condition.

These are possible causes for failing to execute the event procedure for a PROCEDURE-COMPLETE event. All of these failures raise a STOP condition in the context of the WAIT-FOR statement:

– The procedure handle referenced by the EVENT-PROCEDURE-CONTEXT attribute is no longer valid.

– The internal procedure specified by the EVENT-PROCEDURE attribute cannot be found.

– The parameters to the internal procedure specified by the EVENT-PROCEDURE attribute are not all INPUT parameters.

– The parameter signature of the internal procedure specified by the EVENT-PROCEDURE attribute does not match the output parameters returned in the response message for the asynchronous request.

For SpeedScript, the WAIT-FOR statement instructs WebSpeed to stop executing the current block until the WEB-NOTIFY event occurs. The WEB-NOTIFY event is intended for internal use only, it does not apply to SpeedScript programming.

See also DISABLE statement, ENABLE statement, ON statement, Trigger phrase, WAIT-FOR statement (.NET and ABL), Widget phrase

WAIT-FOR statement (.NET and ABL) (Windows only; GUI for .NET only)

This WAIT-FOR statement instructs the AVM to stop executing the current block and remain in a wait state (blocking) until a .NET method that it calls returns. The AVM continues to respond to all incoming ABL events (see the WAIT-FOR statement (ABL only) reference entry) as well as .NET events, and it executes any associated triggers, event procedures, or .NET event handlers while in this wait state.

Note: ABL supports a separate version of the WAIT-FOR statement (ABL WAIT-FOR) that blocks only for ABL events. For more information, see the WAIT-FOR statement (ABL only) reference entry.
**WAIT-FOR statement (.NET and ABL)**

**Syntax**

```plaintext
WAIT-FOR { object-reference | type-name } : method-name ( [ parameters ] )
[ SET return-value ]
```

**object-reference**

A reference to an object that generally inherits from the .NET class `System.Windows.Forms.Form` or `System.Windows.Forms.CommonDialog`. OpenEdge provides a particular subclass of `System.Windows.Forms.Form`—the `Progress.Windows.Form` class—which you can use to create .NET forms in an ABL session that co-exist more naturally with ABL windows.

**type-name**

The type name of a .NET class that provides a static blocking method, most commonly `System.Windows.Forms.Application`. With an appropriate USING statement, you can also specify the type by its unqualified class name (`Application`).

**method-name**

**parameters**

Parameters for the method specified by `method-name`.

**SET return-value**

Provides the return value from the method, `method-name()`, which is set when the WAIT-FOR statement completes execution. The `return-value` can be a variable, property, or field that has the same data type as the `method-name()` return value, typically `System.Windows.Forms.DialogResult`.

To use this option, `method-name()` must be a non-VOID method. If you specify this option for a VOID method, such as `System.Windows.Forms.Application:Run()`, ABL raises a compile-time error.

For more information on .NET input-blocking methods that you can call in the WAIT-FOR statement, see the notes of this reference entry.

**Example**

The ABL-derived .NET class, `r-WaitForms`, inherits the `Progress.Windows.Form` class to implement a non-modal .NET form. When you try to close the displayed form, a dialog box appears that prompts if you want the form to complete closing or not. If you choose to complete closing, the form closes. If you choose to cancel the closing, the form remains displayed, and you can try to close the form, again.
When you instantiate r-WaitForms, it initializes and subscribes a handler (the Form_Closing( ) method) to the FormClosing event of the form. You can then display the form by calling the DoWait( ) method on the r-WaitForms instance. This method executes the WAIT-FOR statement, which calls the .NET input-blocking method System.Windows.Forms.Application:Run( ). (For more information on this method, see the notes.) When you try to close the displayed form, this causes the non-modal form to publish its FormClosing event, which executes the Form_Closing( ) method to handle the event.

rDialog:Dispose( ). /* Dispose modal form object */
END METHOD. /* Form_Closing */

END CLASS.

r-WaitForms.cls (2 of 2)
The Form_Closing( ) method passes INPUT parameters from .NET for the FormClosing event. One of these parameters is a System.Windows.Forms.FormClosingEventArgs object, which contains a Cancel property whose setting allows the event handler to either complete the FormClosing event or interrupt and cancel the FormClosing event. To determine how to set this property, the event handler instantiates, initializes, and displays another Progress.Windows.Form class (rDialog) as a modal dialog box.

The dialog box contains two buttons, rOKButton and rCancelButton, whose DialogResult properties are set to the System.Windows.Forms.DialogResult enumeration values OK and Cancel, respectively. The event handler displays rDialog as a modal form by executing the WAIT-FOR statement, which calls the modal input-blocking method System.Windows.Forms.Form:ShowDialog( ). (For more information on this method, see the notes.)

When you click one of the two dialog buttons, this causes the dialog box to close and the ShowDialog( ) method to return. This automatically sets the DialogResult property on rDialog to the value of the DialogResult property on the button that you have clicked and also returns the same property value as the value of ShowDialog( ), which the WAIT-FOR statement assigns to the variable, enDialogResult. The event handler then uses the static AreEqual( ) method on the Progress.Util.EnumHelper class to test the value of enDialogResult and set the e:Cancel property to either complete the FormClosing event or cancel the FormClosing event and leave the non-modal form open for further input. The Dispose( ) method call at the end of the event handler is required to allow the modal form object to be garbage collected (see the notes).

**Note:** The calls to System.Windows.Forms.MessageBox:Show( ) display a message box similar to the ABL MESSAGE statement with the VIEW-AS ALERT-BOX option.

To instantiate r-WaitForms and display the non-modal form, you can thus run a procedure with code like this:

```plaintext
DEFINE VARIABLE rWaitForms AS CLASS r-WaitForms NO-UNDO.

rWaitForms = NEW r-WaitForms( ).
rWaitForms:DoWait( ).
```

**Notes**
- If you use any .NET forms in an ABL session, you can execute only one .NET WAIT-FOR statement that processes events for all .NET non-modal forms and their controls. This statement must be the first WAIT-FOR statement for processing non-modal events in your application. Following this statement, from event handlers and trigger blocks, you can execute multiple input-blocking statements to process any modal .NET form or ABL dialog box. ABL events for non-modal windows and their child widgets, or for non-GUI ABL features, such as asynchronous remote procedure calls and socket operations, all work in the context of this single non-modal .NET WAIT-FOR statement.

**Caution:** Using stacked input-blocking statements other than for dialog boxes is not recommended. If you do so, you must take special care to ensure that any WAIT-FOR statements that you simultaneously execute to process non-modal events complete their execution in reverse order of invocation. Otherwise, your application will have unpredictable behavior.
To block on any number of non-modal .NET forms (and ABL windows), you must use a WAIT-FOR statement that executes the System.Windows.Forms.Application:Run() input-blocking method (as shown for the example class, r-WaitForms):

**Syntax**

```csharp
```

You can specify `form-object-ref` as an object reference to a single .NET non-modal form object, on which the WAIT-FOR statement blocks, displays, and waits to close. If you specify `form-object-ref`, the statement also displays any additional non-modal forms that you have previously initialized by setting their Visible properties to TRUE or by invoking their Show() methods. However, .NET automatically displays `form-object-ref`, itself, without having to set its Visible property or run its Show() method. You can also use triggers, event procedures, and .NET event handlers to create and display additional non-modal .NET forms (or ABL windows) after the WAIT-FOR statement blocks for events.

The conditions for unblocking this WAIT-FOR statement differ, depending on whether you specify `form-object-ref`. However, whatever conditions unblock the WAIT-FOR statement also automatically close any open .NET forms. This is different from ABL windows, which you must explicitly open and close using ABL statements or widget attributes without regard to the execution of a WAIT-FOR statement.

With `form-object-ref`, the WAIT-FOR statement unblocks and continues execution with the following statement if one of the following actions occurs:

- Your application explicitly calls the `form-object-ref:Close()` method, which automatically calls the Dispose() method to garbage collect the form.

- The user clicks the form Close (X) button in the upper right corner of the `form-object-ref` form, and you do not cancel the action in a handler for the FormClosing event, as in the example. This action also automatically calls the `form-object-ref:Close()` method.

When you use any of these techniques to unblock the WAIT-FOR statement, all currently displayed non-modal forms close, in addition to the form specified by `form-object-ref`, and including any non-modal .NET forms that were created and displayed after the WAIT-FOR statement blocked.

**Caution:** If you are executing the READKEY statement within a trigger or event handler while blocking on a `form-object-ref`, and the user clicks the form Close (X) button, the ABL application shuts down unconditionally. For example, the following READKEY loop can cause this shutdown to occur:

```csharp
DO WHILE LASTKEY != KEYCODE("F3"):
  READKEY.
  IF LASTKEY = KEYCODE("F3") THEN RETURN.
END.
```

This shutdown occurs because .NET generates a WM_QUIT message in response to clicking the Close (X) button that READKEY interprets (by design) as a message to shut down the application.
Caution: You might have a problem displaying message boxes after invoking `Application:Exit()` or `Application:ExitThread()`. One way this can happen: if you use any two of the techniques for unblocking the WAIT-FOR, such as by calling `Close()`, then calling `Application:Exit()`, any subsequent executions of the MESSAGE statement with the VIEW-AS ALERT-BOX option or any subsequent calls to `System.Windows.Forms.MessageBox:Show()` might not display the specified message box and the user will hear a beep sound instead.

If you do not specify `form-object-ref`, the statement displays and blocks for input on any non-modal forms that you have previously initialized by setting their `Visible` properties to TRUE or by invoking their `Show()` methods. Without `form-object-ref`, you also do not need to have a .NET form instantiated before you execute the WAIT-FOR statement. Without any non-modal .NET form created, this statement processes ABL events until you create and initialize your first .NET non-modal form for display in an associated event handler or trigger, at which point the same WAIT-FOR statement processes both .NET and ABL events.

Also, if you do not specify `form-object-ref`, the WAIT-FOR statement unblocks and continues execution with the following statement only when you invoke the `System.Windows.Forms.Application:Exit()` method at some point in the ABL session. This method closes all non-modal .NET forms that are currently open before unblocking the WAIT-FOR statement. Note that using this technique, you must be sure to create and initialize at least one .NET form or ABL window (non-modal or modal) so there are active components to work with during the input-blocking state. Otherwise, the blocking WAIT-FOR statement blocks indefinitely or until the user presses `CTRL+BREAK`.

Note: When working with any displayed non-modal form, except the form specified by `form-object-ref`, the user (using the Close (X) button) or the application (using the `Close()` method) can close the form. However, this does not by itself unblock the blocking WAIT-FOR statement. If you want the WAIT-FOR to unblock other than by closing the form specified by `form-object-ref`, your application must call `Application:Exit()`.

- To block on a .NET modal dialog box, you must use a WAIT-FOR statement that executes the `ShowDialog()` input-blocking method on the specified form object (as shown for `rDialog` in the example class, `r-WaitForms.cls`):

**Syntax**

```plaintext
WAIT-FOR dialog-object-ref:ShowDialog ( [ parent-form ] )
```

This causes the WAIT-FOR statement to display the form specified by the `dialog-object-ref` object reference, and block for input on that form as a dialog box. You can also specify the object reference of a form (parent-form) that becomes the parent of the dialog box referenced by `dialog-object-ref`. (This allows the .NET dialog box to display centered over the parent form.)

Note that by convention, every .NET class that can implement a modal dialog box has a `ShowDialog()` method, such as `System.Windows.Forms.Form` and `System.Windows.Forms.CommonDialog`, as well as classes that derive from them, like...
System.Windows.Forms.OpenFileDialog. Therefore, this syntax for the WAIT-FOR statement allows you to open all these different types of dialog boxes.

**Note:** The System.Windows.Forms.MessageBox class does not work this way. Instead, it is similar to the MESSAGE statement with the VIEW-AS ALERT-BOX option, which handles its own input without events. Similarly, you can only open a MessageBox by invoking its static Show( ) method outside of a WAIT-FOR statement.

With dialog-object-ref:ShowDialog( ), the WAIT-FOR statement unblocks and continues execution with the following statement if one of the following actions occurs:

- The user clicks the dialog box Close (X) button in the upper right corner of the dialog box.
- You set the dialog-object-ref:DialogResult property (if the form class supports it) to a valid System.Windows.Forms.DialogResult enumeration value.
- You call the dialog-object-ref:Close( ) method. Note that calling this method also automatically calls the Dispose( ) method on the form, making the form object available for garbage collection.

For any of these actions, the FormClosing and FormClosed events are also published on dialog-object-ref, and you can handle the FormClosing event in order to prevent the form from being closed by cancelling the action, as shown in the example.

**Caution:** Unlike for non-modal forms, when the user clicks the Close (X) button on a dialog box, or when you set the value of the dialog-object-ref:DialogResult property, the .NET Framework does not automatically call the Close( ) method on dialog-object-ref and therefore does not also call the Dispose( ) method. Instead, .NET hides the form so it can be shown again without creating a new instance of the dialog box. Because of this behavior, when the form is no longer needed by your application, you must call the dialog-object-ref:Dispose( ) method to enable garbage collection for the form and all the .NET controls that it contains.

If the form contains any ABL-derived controls (including any ABL-derived control containers, such as user controls), those controls will also not be garbage collected until you call Dispose( ), because the form itself is still holding a reference to them. Thus, calling Dispose( ) on the modal form also causes Dispose( ) to be called on these ABL-derived controls, which enables them for garbage collection, again, as long as there are no other references to them in the ABL session.

At this point, you can check the user response to the dialog box. Note that ShowDialog( ) returns a DialogResult (enumeration) value with the result of the dialog box. You can access this value using the SET option (as shown in the r-WaitForms.cls example) or by checking the dialog-object-ref:DialogResult property (if the form object is still available and the class supports it).

**Note:** Not all .NET form classes provide a public DialogResult property—for example, System.Windows.Forms.FileDialog. For a form that does not provide this property, you can handle dialog box results in the following ways: 1) by using the SET option to return the form’s ShowDialog( ) method value, 2) by using event handlers subscribed to the events that the form provides, for example, the FileOk
or HelpRequest event, or 3) by testing the values of properties that might otherwise be set depending on input to the dialog box, such as the FileName property of the System.Windows.Forms OpenFileDialog object.

.NET does not set the dialog-object-ref: DialogResult property automatically except in two cases:

- The user clicks the dialog box Close (X) button in the upper right corner, which sets the property to the DialogResult: Cancel enumeration value.

- The user clicks a button (or any control that implements the System.Windows.Forms.IButtonControl interface) contained by the dialog box whose DialogResult property you have set with a valid DialogResult enumeration value. In this case, .NET automatically sets the dialog-object-ref: DialogResult property to the value of the button property.

Otherwise, your application must set the value of dialog-object-ref: DialogResult directly, typically in an event handler. Note that if you want .NET to automatically set the dialog-object-ref: DialogResult property from a button DialogResult property, your application must initialize the DialogResult value for the button property before the user clicks a given button.

- You can detect that a specific form is closing by handling its FormClosing event; you can detect that a specific form has already closed by handling its FormClosed event. However, note that the Closed event does not fire for non-modal .NET forms that you close by calling Application: Exit( ) and that are not specified by the form-object-ref parameter passed to the Application: Run( ) method.

Caution: Do not delete the ABL object reference to the object (sender) that publishes a FormClosing event from within its FormClosing event handler. This causes the FormClosing event to be published a second time. If you need to delete the sender for an event that is associated with closing a form before the AVM garbage collects it, execute the DELETE OBJECT statement for the sender within a handler for its FormClosed event.

Note: .NET supports a Closing and Closed event on forms. However, use the FormClosing and FormClosed events, instead, because they work better.

- If you specify a non-blocking method in a WAIT-FOR statement, the method executes and the WAIT-FOR immediately returns, resuming execution with the next available statement. ABL does not prevent this. However, the WAIT-FOR statement, in this case, works no differently than invoking the method as a statement by itself.

Note: Progress Software Corporation recommends that you do not invoke non-blocking methods using the WAIT-FOR statement.

- The one WAIT-FOR statement that you execute for non-modal .NET forms after setting their Visible properties to TRUE or by invoking their Show( ) methods, must call the Application: Run( ) method to make the forms visible and usable. If you execute any other form of the WAIT-FOR statement after making non-modal .NET forms visible, such as one that blocks for an ABL event (even a developer event, such as U1 OF
THIS-PROCEDURE), the ABL virtual machine (AVM) raises STOP on this WAIT-FOR statement.

- You cannot set the Visible property or call the Show( ) method on a modal .NET form before executing a WAIT-FOR statement on the ShowDialog( ) method. If you execute a WAIT-FOR statement that calls the ShowDialog( ) method on a modal .NET form that you have previously made visible, .NET raises a run-time exception.

- Once you execute a non-modal WAIT-FOR statement that calls the Application:Run( ) method, the statement goes into a wait state that allows any event handlers or triggers to run in response to all types of ABL-supported events, including .NET events, ABL UI events, and ABL non-UI events (such as socket events). In the associated event handlers or triggers, you can then create and display additional .NET non-modal forms (by setting their Visible properties or invoking their Show( ) methods) or ABL non-modal windows (for example, by setting their VISIBLE attributes to TRUE, executing DISPLAY statements, or executing a VIEW statement), and the existing WAIT-FOR statement processes events associated with these new non-modal .NET forms or ABL windows in addition to any other events it is already processing. To open modal dialog boxes (.NET or ABL) from an event handler or trigger, you must execute an additional WAIT-FOR statement for each dialog box that you open. Each such WAIT-FOR statement then blocks until its associated modal dialog box is closed, allowing the event handler or trigger that invoked the statement to resume execution.

- .NET does not support blocking for multiple non-modal forms simultaneously at more than one point in an application. If you attempt to execute more than one non-modal WAIT-FOR statement that calls Application:Run( ) by invoking a second such WAIT-FOR statement in an event handler or trigger, .NET raises an exception, which in turn raises STOP on this second WAIT-FOR statement.

**Caution:** After you execute an additional WAIT-FOR statement that calls Application:Run( ), even if you trap the STOP condition with ON STOP, .NET does not allow another call to Application:Run( ) in the same session. You must exit the ABL session and fix the application to avoid such simultaneous calls to Application:Run( ).

- You must execute a separate WAIT-FOR statement for each modal .NET dialog box or ABL dialog box that you open. The modal nature of each dialog box guarantees that the corresponding WAIT-FOR statements unblock and resume execution with the statements that follow them in order of the most recently opened dialog box. However, while blocking on any .NET or ABL modal dialog box, you cannot then execute a non-modal WAIT-FOR statement calling Application:Run( ), even if no previous non-modal WAIT-FOR statement is still in a wait state. Attempting to call a non-modal WAIT-FOR statement while any modal .NET dialog box or ABL dialog box is open raises a run-time error.

- If you add non-modal .NET forms to an existing ABL application that already contains WAIT-FOR statements to process non-modal ABL GUI and non-GUI events, replace these WAIT-FOR statements (except those that block on ABL modal dialog boxes) with a single WAIT-FOR statement that calls Application:Run( ). In order to have an active .NET form in your application, you must execute your latest (and usually only) WAIT-FOR statement in the format that calls a .NET input-blocking method (for example, waiting on Application:Run( )) so that it is in effect to process .NET events. This allows the application to handle the same ABL events after adding .NET forms that it handled before you added the .NET forms.
You cannot use the APPLY statement to force a WAIT-FOR statement that is blocking on .NET forms to unblock and continue execution with the statement following the WAIT-FOR statement. Instead, call the appropriate .NET method (for example, Close() or Application:Exit()) to unblock the WAIT-FOR statement and continue with the next statement.

To handle a particular .NET event while the WAIT-FOR statement that processes the event is executing, you must subscribe a .NET event handler to the specified event using the Subscribe() event method before the event is raised. For more information on event methods and event handlers for .NET events, see the “Class Events Reference” section on page 1953.

If an ABL handler for a .NET event raises an unhandled error condition or throws an error object out of the handler, the AVM does not throw a .NET Exception back to the .NET Common Language Runtime (CLR), but displays a message to the default output device and continues blocking for events.

You cannot invoke the non-modal .NET System.Windows.Forms.Application:Run() method or the .NET ShowDialog() method used to display a modal dialog box in any ABL context other than in a WAIT-FOR statement. Any attempt to do so raises a run-time error.

See also Type-name syntax, USING statement, WAIT-FOR statement (ABL only)

**WEEKDAY function**

Evaluates a date expression and returns the day of the week as an INTEGER value from 1 (Sunday) to 7 (Saturday) for that date.

**Syntax**

```plaintext
WEEKDAY ( date )
```

```plaintext
WEEKDAY ( datetime-expression )
```

date

A date expression for which you want the day of the week.

datetime-expression

An expression that evaluates to a DATETIME or DATETIME-TZ. The WEEKDAY function returns the weekday of the date part of the DATETIME or DATETIME-TZ value.

**Example**

This procedure tells you the day of the week that you were born and how many days old you are:
r-wkday.p

```plaintext
DEFINE VARIABLE birth-date AS DATE NO-UNDO
  LABEL "Birth Date".
DEFINE VARIABLE daynum AS INTEGER NO-UNDO.
DEFINE VARIABLE daylist AS CHARACTER NO-UNDO FORMAT "x(9)"
  INITIAL "Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday".
DEFINE VARIABLE dayname AS CHARACTER NO-UNDO
  LABEL "Day You Were Born".
DEFINE VARIABLE daysold AS INTEGER NO-UNDO
  LABEL "Days Since You Were Born".

REPEAT:
  SET birth-date.
  ASSIGN
daynum = WEEKDAY(birth-date)
dayname = ENTRY(daynum, daylist)
daysold = TODAY - birth-date.

  DISPLAY dayname daysold.
END.
```

### WIDGET-HANDLE function

This function is supported only for backward compatibility. Use the HANDLE function instead.

Converts a string representation of a handle to a valid handle.

#### Syntax

```plaintext
WIDGET-HANDLE ( handle-string )
```

**Caution:** Use this function only to convert a handle previously stored as a string value back to a valid handle. If you convert an arbitrary string to handle using this function and then reference the new handle, a system error will occur. If you use the VALID-HANDLE function to validate a handle generated from an arbitrary string value, a system error will occur.

**handle-string**
A string representation of a handle. Since handles are integer values, the string must contain only numeric characters.

### Widget phrase

References a widget in a statement. The Widget phrase is used in the APPLY, ON, and WAIT-FOR statements.
Note: Does not apply to SpeedScript programming.

Syntax

```
{   FRAME frame
|   [ FIELD ] field [ IN FRAME frame ]
|   column [ IN BROWSE browse ]
|   { MENU | SUB-MENU } menu
|   MENU-ITEM menu-item [ IN MENU menu ]
|   handle
|   system-handle
}
```

FRAME frame

Specifies a frame widget. The frame parameter must be the name of an existing frame.

[FIELD] field [ IN FRAME frame ]

Specifies a field. The FIELD keyword is optional. The field parameter must be the name of an existing field-level widget: a fill-in, editor, text, slider, toggle box, radio set, selection list, combo box, button, image, rectangle, or browse. Use the IN FRAME option to qualify the widget, if necessary.

column [ IN BROWSE browse ]

Specifies a column or cell in a browse widget. Use the IN BROWSE option to qualify the widget, if necessary. For more information on when you can reference browse columns and cells, see the DEFINE BROWSE statement reference entry.

{ MENU | SUB-MENU } menu

Specifies a menu or submenu. The menu parameter must be the name of an existing menu. The menu can be a pop-up menu, pull-down menu, or menu bar. Within the widget phrase, ABL does not distinguish between MENU and SUB-MENU.

MENU-ITEM menu-item [ IN MENU menu ]

Specifies an menu item within a menu. The menu item parameter must be the name of an existing menu item. Use the IN MENU option to qualify the menu item, if necessary.

handle

Variable or field that specifies a valid widget, procedure, or system handle.

system-handle

Specifies a built-in system handle. The system handle parameter must be one of the built-in system handles listed in Table 67.
<table>
<thead>
<tr>
<th>System handle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTIVE-WINDOW</td>
<td>A handle to the ABL window that has most recently received input focus during the session.</td>
</tr>
<tr>
<td>CLIPBOARD</td>
<td>A handle to the system clipboard.</td>
</tr>
<tr>
<td>COLOR-TABLE</td>
<td>A handle to information on the current color table.</td>
</tr>
<tr>
<td>COMPILER</td>
<td>A handle to information on the most recently executed COMPILE statement.</td>
</tr>
<tr>
<td>CURRENT-WINDOW</td>
<td>A settable handle to the default window for the ABL session.1,2</td>
</tr>
<tr>
<td>DEBUGGER</td>
<td>A handle to the Application Debugger.</td>
</tr>
<tr>
<td>DEFAULT-WINDOW</td>
<td>A handle to the static window created by the AVM for the session. Every session has one static window.1</td>
</tr>
<tr>
<td>ERROR-STATUS</td>
<td>A handle to information on the last statement executed with the NO-ERROR option.</td>
</tr>
<tr>
<td>FILE-INFO</td>
<td>A handle to information on an operating system file.</td>
</tr>
<tr>
<td>FOCUS</td>
<td>A handle to the field-level widget that currently has keyboard focus (that is, the current field).</td>
</tr>
<tr>
<td>FONT-TABLE</td>
<td>A handle to information on the current font table.</td>
</tr>
<tr>
<td>LAST-EVENT</td>
<td>A handle to the last event received by the program.</td>
</tr>
<tr>
<td>RCODE-INFO</td>
<td>A handle to information on an ABL r-code file.</td>
</tr>
<tr>
<td>SELF</td>
<td>A handle for the widget associated with the currently executing user-interface trigger.</td>
</tr>
<tr>
<td>SESSION</td>
<td>A handle to information on the current ABL session.</td>
</tr>
<tr>
<td>SOURCE-PROCEDURE</td>
<td>A handle to the procedure file that contains the original invocation (RUN statement or function invocation) of the current internal procedure or user-defined function.</td>
</tr>
</tbody>
</table>
A working directory is the default operating system directory where an ABL session reads or writes most data files (such as text and XML files) that are specified with a relative pathname. An ABL session can have one active working directory at a time that is the current working directory. In OpenEdge, the current working directory can be one of the following:

- When you run an ABL session that is started directly from a shortcut in the OpenEdge program group in Windows, such as the OpenEdge Desktop, the current working directory is the working directory that you specified during OpenEdge installation (C:\OpenEdge\WRK by default).
- When you run an ABL session (OpenEdge AVM) from within OpenEdge Architect, the current working directory is the working directory you specified for the project you are currently working in.
- When you start an ABL client directly from the command line, for example, by running the OpenEdge pro or mpro command in the OpenEdge Proenv command window, the current working directory is the active working directory at the point you run the command.

Notes
- The current working directory is distinct and different from PROPATH. PROPATH is an environment variable that specifies one or more directories that an ABL session searches in order to locate and execute ABL code in any procedure file, include file, class definition file, or r-code file that you specify with a relative pathname.
• The ABL session does not search the current working directory for data files that you access in order to load the contents of an editor widget. Instead, if you pass a relative pathname to the INSERT-FILE( ) method or the READ-FILE( ) method, the ABL session searches PROPATH to locate and read the file into the associated editor widget. This is an exception to how ABL generally handles access to data files specified with a relative pathname.

See also  PROPATH function, PROPATH statement

---

**YEAR function**

Evaluates a date expression and returns the year value of that date, including the century, as an INTEGER value.

**Syntax**

```
YEAR ( date )
```

```
YEAR ( datetime-expression )
```

date

A date expression for which you want to determine the year.

datetime-expression

An expression that evaluates to a DATETIME or DATETIME-TZ. The YEAR function returns the year of the date part of the DATETIME or DATETIME-TZ value.

**Example**

This procedure uses the YEAR function to determine if an Order date is in this century or the next, and then uses a different display format for each:

```
DEFINE VARIABLE outfmt AS CHARACTER NO-UNDO.
DEFINE VARIABLE orddate AS CHARACTER NO-UNDO
LABEL "Order Date" FORMAT "x(10)".

FOR EACH Order NO-LOCK:
ASSIGN
   orddate = STRING(Order.OrderDate, outfmt).
DISPLAY Order.OrderNum orddate Order.Terms.
END.
```

See also  ADD-INTERVAL function, DATE function, DATE-FORMAT attribute, DATETIME function, DATETIME-TZ function, DAY function, ETIME function, INTERVAL function, ISO-DATE function, MONTH function, MTIME function, NOW function, TIME function, TIME-SOURCE attribute, TIMEZONE function, TODAY function, YEAR-OFFSET attribute
Widget Reference

This section contains reference entries that describe the ABL widgets. Widgets are handle-based objects that provide visual representations of data and other elements of a user interface.

Like all handle-based objects, widgets support attributes and methods to access and manipulate widget state and behavior. Widgets also support events to which an application can respond to interact with the state and behavior of each widget. For more information on the attributes and methods listed for each widget, see the “Handle Attributes and Methods Reference” section on page 1271. For more information on the events listed for each widget, see the “Handle-based Object Events Reference” section on page 1827. For information on non-visual handle-based objects, see the “Handle Reference” section on page 1189.

You may consider a user-interface widget to be supported for all interfaces and on all operating systems unless otherwise indicated in the reference entry. These user-interface widgets do not apply to SpeedScript programming.

Because widgets are not realized in batch mode, you cannot use any method or attribute that requires the widget to be realized in batch mode.

Note: Of the common attributes listed for the following widgets, BGCOLOR, FGCOLOR, FONT, MOVABLE, RESIZABLE, and SELECTABLE apply only to graphical interfaces; DCOLOR and PFCOLOR apply only to character interfaces. In character interfaces, all attributes and methods that reference pixels (for example HEIGHT-PIXELS) use a system default pixel value for the equivalent value in characters.

The following descriptions refer to both compile-time and run-time behavior, features that the language generally supports and determines at compile time and actions directed by using these features at run time. When describing compile-time features or actions, this section references ABL or the ABL compiler. When describing ABL-directed actions taken at run time, this section references the ABL Virtual Machine (AVM).
A browse widget lets you see data and select records from all the records associated with a database query. You can define a static browse widget with the `DEFINE BROWSE` statement or a dynamic browse widget with the `CREATE BROWSE` statement. A browse can be either a read-only tool for browsing through records, or it can be an editing tool for updating records, depending on the options you specify.

You can move and resize the browse and its components. Specifically, in graphical interfaces, you can move and resize the browse, move and change the width of the browse-column, and change the height of the browse-row. You can do all this through direct manipulation (by pointing, clicking, and dragging) and through ABL.

You can also use the mouse wheel to scroll the browse widget horizontally and vertically in Windows. When you rotate the mouse wheel up and down, the browse scrolls vertically up and down. When you rotate the mouse wheel up and down while holding down the `CTRL` key, the browse scrolls horizontally left and right. You can specify the number of rows the browse scrolls up and down per click of the mouse wheel on the Wheel tab in the Windows Mouse Properties dialog box (accessed through the Windows Control Panel).

The following figure shows a read-only browse widget:

![Read-only browse widget](image1)

The following figure shows an updateable browse. Note the inline editing capability in the focused row:

![Updateable browse](image2)
**Accessing browse attributes and methods**

When accessing browse attributes and methods, it is important to understand the scope of each attribute and method. An attribute or method can apply to:

- The browse widget as a whole.
- A single browse column. In this case, any attribute or method that applies to a browse column, applies to:
  - All cells in the browse column (that is, all cells of the given column for all rows of the browse)
  - Any type of browse column (fill-in, combo-box, or toggle-box), except where noted
- A single browse cell. In this case, the attribute or method applies to only the given cell at the intersection of the referenced column and the focused row.
- Both the browse as a whole and a column or cell. For example, in the same trigger, you could change the background color of the whole browse to blue and the background color of the current cell to yellow.

When accessing attributes and methods that apply to a browse widget as a whole, you must reference the browse widget using its name or handle, as shown in the following syntax examples:

```/* For a static browse */
browse-name:attribute-or-method-name IN FRAME frame-name
/* For a dynamic or static browse */
browse-handle:attribute-or-method-name```

The IN FRAME qualifier is only necessary for a static browse to avoid ambiguity.

When accessing attributes and methods that apply to a browse column or cell, you must reference the browse column or cell using the browse column’s name or handle, as shown in the following syntax examples:

```/* For a static browse column */
column-name:attribute-or-method-name IN BROWSE browse-name
/* For a dynamic or static browse column */
column-handle:attribute-or-method-name```

The IN BROWSE qualifier is only necessary for a static browse to avoid ambiguity, but it is good programming practice to always include it, especially when you reference the same field as a separate widget type.

To access attributes and methods for a specific browse cell, you must be sure that a row is selected. You typically access browse cell attributes and methods in a ROW-DISPLAY trigger.

For more information about accessing widget attributes and methods, see the “Handle Attributes and Methods Reference” section on page 1271.

**Attributes**

The following table lists all the attributes for the browse widget and their scope:
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Applies to</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOW-COLUMN-SEARCHING attribute</td>
<td>Browse</td>
</tr>
<tr>
<td>AUTO-COMPLETION attribute</td>
<td>Column</td>
</tr>
<tr>
<td>AUTO-RESIZE attribute</td>
<td>Column</td>
</tr>
<tr>
<td>AUTO-RETURN attribute</td>
<td>Column</td>
</tr>
<tr>
<td>AUTO-VALIDATE attribute</td>
<td>Browse</td>
</tr>
<tr>
<td>AUTO-ZAP attribute^2</td>
<td>Cell</td>
</tr>
<tr>
<td>BGCOLOR attribute</td>
<td>Browse, Column, Cell</td>
</tr>
<tr>
<td>BUFFER-FIELD attribute</td>
<td>Column</td>
</tr>
<tr>
<td>COLUMN attribute</td>
<td>Browse, Column</td>
</tr>
<tr>

<td>Browse</td>
</tr>
<tr>
<td>VALIDATE( ) method</td>
<td>Browse, Column</td>
</tr>
</tbody>
</table>

1. This method applies only to combo-box browse columns.
2. This method applies only to fill-in and combo-box browse columns.
A button widget represents a push button on the screen. The button can contain a textual label or it can have images associated with its pressed and unpressed states. You can define a static button with the `DEFINE BUTTON` statement. You can create dynamic buttons with the `CREATE widget` statement. This figure shows three buttons:

<table>
<thead>
<tr>
<th>Event</th>
<th>Applies to</th>

1153
COMBO-BOX widget

A combo box is a field-level widget that combines the functionality of a fill-in field, radio set, and selection list into one fill-in and drop down list. You can set up a static combo box widget with the VIEW-AS phrase. You can create a dynamic combo box with the CREATE widget statement. The following figure shows a combo box:

<table>
<thead>
<tr>
<th>Rep.</th>
<th>HXM</th>
</tr>
</thead>
<tbody>
<tr>
<td>RBB</td>
<td></td>
</tr>
<tr>
<td>DKP</td>
<td></td>
</tr>
<tr>
<td>DOS</td>
<td></td>
</tr>
<tr>
<td>GPE</td>
<td></td>
</tr>
<tr>
<td>HXM</td>
<td></td>
</tr>
<tr>
<td>JAL</td>
<td></td>
</tr>
<tr>
<td>KIK</td>
<td></td>
</tr>
<tr>
<td>RDR</td>
<td></td>
</tr>
<tr>
<td>SLS</td>
<td></td>
</tr>
</tbody>
</table>

</tbody>
</table>
A control-frame is a field-level widget that holds an ActiveX control that you select for your application from the OpenEdge AppBuilder. A control-frame is always created dynamically.

A control-frame has no visualization.

The AVM instantiates two separate but related objects when you create a control-frame:

- A control-frame widget
- A control-frame COM object

The widget itself provides a connection between the ActiveX control and the ABL user interface. When the widget is realized, the AVM creates a COM object that provides the real ActiveX control container support. Thus, the control-frame widget provides widget attributes and methods to manage the ABL side of the interface, while the control-frame COM object provides COM object properties and methods to gain access to the control itself.

When you insert an ActiveX control into your application, the AppBuilder creates a control-frame with the `CREATE widget statement` and specifies a default name (NAME attribute value) for the widget. The AppBuilder creates a design-time instance of the ActiveX control based on the control you select in the AppBuilder, making its design-time properties available to the AppBuilder. When you save your application, the AppBuilder saves the design-time instance in a separate file (with .wrx extension) for use at run time.

At run time, your application accesses the control indirectly through the control-frame widget. First, you use the COM-HANDLE attribute to return a component handle to the control-frame COM object. Second, you use this handle to access properties and methods of the control-frame COM object, which provide access to the ActiveX control itself.

Notes

- You must use the AppBuilder to incorporate one or more ActiveX control instances into an ABL application. The AppBuilder, operating in design mode, provides the facilities to set design-time properties for ActiveX controls.

- After incorporating ActiveX controls into an application with the AppBuilder, the resulting window file, when compiled and executed, interacts with the ActiveX controls at run time.

- To access a loaded ActiveX control at run time, use the control-frame COM-HANDLE attribute to get a handle to the control-frame COM object. To return a handle to the control, use the design-time name of the ActiveX control as a property of the control-frame COM object. For example:

```plaintext
/* Control Frame widget */
DEFINE VARIABLE hCFwid AS HANDLE NO-UNDO.
/* Control Frame COM Object */
DEFINE VARIABLE hCFcom AS COM-HANDLE NO-UNDO.
/* ActiveX Control */
DEFINE VARIABLE hDateSpin AS COM-HANDLE NO-UNDO.

/* Control-frame created with handle hCFwid and loaded with ActiveX control named DateSpin. */
ASSIGN
  hCFcom = hCFwid:COM-HANDLE
  hDateSpin = hCFcom:DateSpin.
```

As an alternative, use the COM object Controls property to return a handle to a control collection. Use the control collection Item(1) method call to return the handle to the ActiveX control. (This control collection object provides support for searching multiple ActiveX controls in a control-frame, available in a future release of OpenEdge.)
• You can use a single ActiveX control more than once in a single window file. Each time
you insert the control, the AppBuilder creates a separate control-frame for it with a unique
NAME attribute value.

• Some control-frame widget attributes correspond to control-frame COM object properties
so that setting one sets the other. You must directly set and read all ActiveX control
run-time properties using a handle (also a COM-HANDLE value) to the control.

• To trap control-frame events, use the ON statement, as with any ABL widget. To trap
events for the associated ActiveX control, you must use ActiveX control (OCX) event
procedures. Also, to “apply” an ActiveX control event from ABL, run the event procedure
directly, like any ABL internal procedure. The APPLY statement has no effect on ActiveX
controls. For more information, see the reference entries for the PROCEDURE statement
and RUN statement.

• ABL control-frame events are mutually exclusive with associated ActiveX control events.
That is, only one event handler, either an ON trigger or an event procedure, fires for a
single event.

See also CREATE widget statement, The chapter on ActiveX control container support in OpenEdge
Development: Programming Interfaces

DIALOG-BOX widget

A dialog box is a special type of frame that is displayed in its own window. A dialog box differs
from a window in two major respects:

• It has a system window ventilator, but has no affordances for minimizing or maximizing.

• While a dialog box has input focus, your application cannot perform any other processing
until you complete the input or otherwise close the dialog box. That is, it is modal.

You can specify that a frame be displayed as a dialog box by using the VIEW-AS phrase. You
can create a dynamic dialog box with the CREATE widget statement.

A dialog box can contain a frame family acting as the root frame. However a dialog box cannot
be a child of another frame or dialog box; it can only be parented by a window.

The following example dialog box contains:

• Two fill-ins

• One radio set

• One toggle box

• Five buttons

Note

Generally, your application must wait to complete dialog box input before continuing with other processing. However, the WAIT-FOR statement for the procedure can also respond to an event for a procedure handle as long as the widget in the WAIT-FOR statement widget list is a procedure handle.

</table>

See also CREATE widget statement, VIEW-AS phrase

FIELD-GROUP widget

A field group is the hidden parent of field-level widgets and child frames owned by a parent frame or dialog box. Thus, field groups are the actual children of frames and dialog boxes. A frame contains the following field groups:

- A background field group (which includes the frame header)
- For a one-down frame or dialog box: a single data field group containing field-level widgets and child frames
- For a multiple-down frame: one data field group for each data iteration in the frame

A field group has no visible representation. You cannot explicitly define or create field groups. They are generated automatically when frames are defined or created.

Attributes

<table>
<thead>
<tr>
<th>COLUMN attribute</th>
<th>DYNAMIC attribute</th>
<th>FIRST-CHILD attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST-TAB-ITEM attribute</td>
<td>FOREGROUND attribute</td>

</tbody>
</table>

Note: For a field group, all of these attributes are read-only except for PRIVATE-DATA and SENSITIVE.

Methods

| GET-TAB-ITEM( ) method | – |
FILL-IN widget

A fill-in widget is the simplest form of data representation. Within a fill-in, the field value is displayed as a string of characters that you can edit. A fill-in is the default representation for data. You can explicitly set up a static fill-in with the VIEW-AS phrase. You can create a dynamic fill-in with the CREATE widget statement.

Note: The default sizing of fill-ins occurs only when you use the default font. When you explicitly specify a font, the AVM uses the average width of that font.

1. This method also applies to fill-in browse columns.
A frame is a display area within a window that can group together (contain) a set of field-level widgets and child frames. In addition to default frames set up by ABL, you can set up static frames with the Frame phrase or DEFINE FRAME statement. You can create a dynamic one-down frame with the CREATE widget statement.

Related field-level widgets and child frames are actually parented by a single field group widget, which is owned, in turn, by the parenting frame. You parent static field-level widgets to a static frame using a DEFINE FRAME, FORM, or FRAME I/O statement. You parent dynamic field-level widgets to any frame by setting the FRAME attribute of each field-level widget to the handle of the parent frame. You can parent frame widgets to any frame by setting the FRAME attribute of each child frame to the handle of its parent frame.

Frames in a parent and child relationship form a frame family, which is a hierarchy of parent and child frames ultimately parented by a window. The top parent frame that is parented by the window is the root frame of the frame family.

The following figure shows a frame family with four frames, including three child frames titled Contact Information, Account Information, and PREVIOUS/NEXT:

¹ Windows only. This event occurs only in dynamic data exchange (DDE) conversations. This event is supported only for backward compatibility. Use the Component Object Model (COM) instead. For more information, see the chapter on DDE in OpenEdge Development: Programming Interfaces.

Notes

- Field-level widgets and child frames are not directly parented by a parent frame. They are parented by field groups that are owned by the parent frame. Thus, you can also parent a child frame by setting the child frame’s PARENT attribute to the handle of a field group in the parent frame.

To access all the field-level widgets and child frames owned by a frame, you must first use the frame’s FIRST-CHILD or LAST-CHILD attribute to find a field group within the frame. You can then use the field group’s NEXT-SIBLING or PREV-SIBLING attribute to find other field groups in the frame. You can use the field group’s FIRST-CHILD or LAST-CHILD attribute to find a field-level widget or child frame within the field group. You can then use the field-level widget’s or child frame’s NEXT-SIBLING or PREV-SIBLING attribute to find other field-level widgets and child frames within the frame.

- Child frames do not inherit the attributes of a parent frame.

- When any of a frame’s field-level widgets or child frames are viewed using the DISPLAY or ENABLE statement, the parent frame also becomes visible unless its HIDDEN attribute
or the HIDDEN attribute of an ancestor widget is TRUE. However, explicitly setting the VISIBLE attribute to TRUE (using the VIEW statement) for a child frame or field-level widget makes all ancestor frames visible, unless the parent or an ancestor window has its HIDDEN attribute set to TRUE.

- Child frames participate in the tab order along with any field-level widgets in the same parent frame. This means that the tab orders of all field-level widgets within a child frame is placed as a group within the tab order of the siblings of that child frame. Thus, tabbing proceeds between the field-level widgets of a root frame and the field-level widgets of all descendant frames. However, tabbing is not supported between sibling root frames (frames parented by a window).

- You specify the position of a child frame relative to the display area of the parent frame. You must specify the position so that the upper left corner of the child frame lies within the display region of the parent frame. Otherwise at run time, when the procedure tries to realize the frame, the AVM raises the ERROR condition.

- When you apply a NEXT-FRAME or PREV-FRAME navigation key function to a field-level widget, focus changes from the current frame family to the next or previous frame family (respectively) parented by the same window. That is, these key functions change focus between root frames, not between descendant frames.

- In character interfaces, the SCROLL-MODE function key is available for a frame only if the SCROLLABLE attribute of the frame is TRUE. Scroll mode allows you to use the CURSOR-RIGHT and CURSOR-LEFT keys to scroll the frame horizontally. The SCROLL-MODE function key toggles scroll mode on and off for a frame that has focus.

See also CREATE widget statement, DIALOG-BOX widget, DEFINE FRAME statement, Frame phrase

**IMAGE widget**

*(Graphical interfaces only)*

An image is a graphic taken from an operating system file. It can be used by itself or within a button. You can define a static image with the DEFINE IMAGE statement, and create a dynamic image with the CREATE widget statement. You can specify an image for a button using the DEFINE BUTTON statement or the button methods for loading images.

See also CREATE widget statement, DIALOG-BOX widget, DEFINE FRAME statement, Frame phrase
A literal widget is the label for a static field. If a field has a side label, you can find the handle of a literal widget by reading the field’s SIDE-LABEL-HANDLE attribute. If the field has a column label, you can find the handle of the literal by examining the children of the frame’s background field group. You cannot create a literal widget dynamically.

**LITERAL widget**

A literal widget is the label for a static field. If a field has a side label, you can find the handle of a literal widget by reading the field’s SIDE-LABEL-HANDLE attribute. If the field has a column label, you can find the handle of the literal by examining the children of the frame’s background field group. You cannot create a literal widget dynamically.
### Methods

<table>
<thead>
<tr>
<th>FRAME-ROW attribute</th>
<th>FRAME-X attribute</th>
<th>FRAME-Y attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>HANDLE attribute</td>
<td>HEIGHT-CHARS attribute</td>
<td>HEIGHT-PIXELS attribute</td>
</tr>
<tr>
<td>HIDDEN attribute</td>
<td>HTML-CHARSET attribute</td>
<td>INPUT-VALUE attribute</td>
</tr>
<tr>
<td>INSTANTIATING-PROCEDURE attribute</td>
<td>MANUAL-HIGHLIGHT attribute</td>
<td>MOVABLE attribute</td>
</tr>
<tr>
<td>NAME attribute</td>
<td>NEXT-SIBLING attribute</td>
<td>PARENT attribute</td>
</tr>
<tr>
<td>PREV-SIBLING attribute</td>
<td>PRIVATE-DATA attribute</td>
<td>RESIZABLE attribute</td>
</tr>
<tr>
<td>ROW attribute</td>
<td>SCREEN-VALUE attribute</td>
<td>SELECTABLE attribute</td>
</tr>
<tr>
<td>SELECTED attribute</td>
<td>SENSITIVE attribute</td>
<td>TYPE attribute</td>
</tr>
<tr>
<td>VISIBLE attribute</td>
<td>WIDTH-CHARS attribute</td>
<td>WIDTH-PIXELS attribute</td>
</tr>
<tr>
<td>WINDOW attribute</td>
<td>X attribute</td>
<td>Y attribute</td>
</tr>
</tbody>
</table>

### Events

The literal widget does not support any events.

### MENU widget

A menu can be a menu bar or a pop-up menu. Menu bars contain sub-menus (specifically, pull-down menus) and in some environments menu items. Pop-up menus contain menu items and sub-menus. You can define a static menu with the DEFINE MENU statement. You can create a dynamic menu with the CREATE widget statement.

The following is a menu bar:

<table>
<thead>
<tr>
<th>File</th>
<th>Edit</th>
<th>Search</th>
<th>Buffer</th>
<th>Compile</th>
<th>Tools</th>
<th>Options</th>
<th>Help</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Find…</td>
<td>Ctrl+F</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Find Next</td>
<td>F9</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Find Previous</td>
<td>Shift+F9</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Replace…</td>
<td>Ctrl+R</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Goto Line…</td>
<td>Ctrl+G</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following is a pop-up menu:
Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Menu-Item Attributes</th>
<th>Developer events</th>
<th>Supported only when the POPUP-ONLY attribute is set to TRUE and the menu is set as a popup for some other widget.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCOLOR</td>
<td>dynamic</td>
<td>MENU-DROP</td>
<td></td>
</tr>
<tr>
<td>HANDLE</td>
<td>HTML-CHARSET</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LAST-CHILD</td>
<td>NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PFCOLOR</td>
<td>POPUP-ONLY</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SENSITIVE</td>
<td>TITLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TYPE</td>
<td>VISIBLE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: Color and font attributes for a menu are ignored in Windows.

Methods

The MENU widget does not support any methods.

Events

See also

CREATE widget statement, DEFINE MENU statement

MENU-ITEM widget

A menu item is an item within a menu or submenu. A menu item can be a rule, a space, or a normal menu item. A normal menu item can be a command or a toggle-box item. Most menu item attributes and all menu item events apply only to normal menu items. You can set up a static menu item within a DEFINE MENU statement or DEFINE SUB-MENU statement. You can create a dynamic menu item with the CREATE widget statement.

The following is a menu containing four menu items:
RADIO-SET widget

Attributes

<table>
<thead>
<tr>
<th>ACCELERATOR attribute</th>
<th>CHECKED attribute</th>
<th>DCOLOR attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>DYNAMIC attribute</td>

</tr>
<tr>
<td>SENSITIVE attribute</td>
<td>SUBTYPE attribute</td>
<td>TOGGLE-BOX attribute</td>
</tr>
<tr>
<td>TYPE attribute</td>
<td>VISIBLE attribute</td>
<td>WINDOW attribute</td>
</tr>
</tbody>
</table>

Note: Color and font attributes for a menu item are ignored in Windows.

Methods

The MENU-ITEM widget does not support any methods.

Events

<table>
<thead>
<tr>
<th>Developer events</th>
<th>CHOOSE (except for toggle-box items)</th>
<th>VALUE-CHANGED (for toggle-box items only)</th>
</tr>
</thead>
</table>

CREATE widget statement, DEFINE MENU statement, DEFINE SUB-MENU statement

RADIO-SET widget

A radio set is a group of values of which only one can be set at any time. You can define a static radio set by using the VIEW-AS phrase with any LOGICAL, CHARACTER, INTEGER, INT64, DECIMAL, or DATE value. You can create a dynamic radio set with the CREATE widget statement. For example:

- Unpaid
- Partially Paid
- Paid in Full

SHADOW-WINDOW widget
(Windows only; GUI for .NET only)

A shadow window widget is a window associated with a .NET form that allows .NET forms and ABL windows to have parenting relationships to each other. A shadow window has no visible representation. It exists solely to support a .NET form and its relationship to ABL windows in an ABL session.

You cannot explicitly create or delete a shadow window. The ABL virtual machine (AVM) automatically creates an associated shadow window when you instantiate a .NET form from the OpenEdge .NET Progress.Windows.Form class, and it automatically deletes the associated shadow window when you delete an instance Progress.Windows.Form.

Attributes

| PARENT attribute |

Methods
The SHADOW-WINDOW widget does not support any methods.

Events
The SHADOW-WINDOW widget does not support any events.

Notes
• To obtain the shadow window handle of a .NET form, read the ProWinHandle property of the associated Progress.Windows.Form instance.

• To parent an ABL window to a .NET form, assign the shadow window handle of the .NET form to the PARENT attribute of the ABL window.

• To parent a .NET form to an ABL window, assign the handle of the ABL window to the PARENT attribute of the shadow window.

• Shadow windows have no NEXT-SIBLING attribute or PREV-SIBLING attribute and therefore do not appear on the session window chain.

• ABL does not create shadow windows for .NET forms that you instantiate from the System.Windows.Forms.Form class. Progress Software Corporation recommends that you always instantiate such forms from Progress.Windows.Form.

See also
Progress.Windows.Form class, ProWinHandle property, WINDOW widget

SLIDER widget

The slider widget represents an integer value as a point on a sliding scale. You can use the VIEW-AS phrase to set up a static slider. You can use the CREATE widget statement to create a dynamic slider. For example:

```
10
```

[Diagram of slider]

</tr>
</tbody>
</table>

### Events

- Default keyboard events
- Developer events
- General direct manipulation events
- Mouse events
Notes

- Only a value of the INTEGER or INT64 data type can be viewed as a slider. If using INT64, the value must remain within the -2147483648 to +2147483647 range.

- In character interfaces, a slider widget has a minimum width that is dependent on the specified maximum value (MAX-VALUE attribute). The minimum height for a slider widget in a character interface is 2 character units. You can specify a value as low as 1.5 character units for the height of a slider in a character interface; however, ABL rounds the value up to 2 character units.

See also CREATE widget statement, VIEW-AS phrase

SUB-MENU widget

A submenu can be a pull-down menu within a menu bar, or a submenu within a pull-down menu or pop-up menu. You can define a static submenu with the DEFINE SUB-MENU statement. You can use the CREATE widget statement to create a dynamic submenu. For example:

Attributes

<table>
<thead>
<tr>
<th>BGCOLOR attribute</th>
<th>DCOLOR attribute</th>
<th>DYNAMIC attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>FGCOLOR attribute</td>
<td>FIRST-CHILD attribute</td>
<td>FONT attribute</td>
</tr>
<tr>
<td>HANDLE attribute</td>
<td>HTML-CHARSET attribute</td>
<td>INSTANTIATING-PROCEDURE attribute</td>
</tr>
<tr>
<td>LABEL attribute</td>
<td>LAST-CHILD attribute</td>
<td>NAME attribute</td>
</tr>
<tr>
<td>NEXT-SIBLING attribute</td>
<td>PARENT attribute</td>
<td>PFCOLOR attribute</td>
</tr>
<tr>
<td>PREV-SIBLING attribute</td>
<td>PRIVATE-DATA attribute</td>
<td>SENSITIVE attribute</td>
</tr>
<tr>
<td>TYPE attribute</td>
<td>VISIBLE attribute</td>
<td>WINDOW attribute</td>
</tr>
</tbody>
</table>

Note: Color and font attributes for a submenu are ignored in Windows.

Methods

The SUB-MENU widget does not support any methods.
TEXT widget

Events

CREATE widget statement, VIEW-AS phrase
**WINDOW widget**

A window is a rectangular area on the screen that can contain frame widgets, parent dialog boxes, and parent other windows. It is surrounded by a standard border and affordances provided by your window system to manipulate the window’s size, location, and appearance on the screen.

The AVM automatically creates one default window for each session. You can create additional dynamic windows with the CREATE widget statement. Each additional window can be parented by the window system, creating siblings (the default) or by another window, creating child and parent window relationships. You create a parent and child relationship between two windows by setting the PARENT attribute of one (the child) to the handle of the other (the parent).

Windows in a parent and child relationship form a window family, which is a hierarchy of parent and child windows ultimately parented by the window system. The top parent window that is parented by the window system is the root window of the window family.

The following figure shows a window family consisting of a root window and its child window:

![Window Family Diagram](image)

**Methods**

- `END-FILE-DROP()` method
- `GET-DROPPED-FILE()` method
- `GET-SELECTED-WIDGET()` method
- `LOAD-ICON()` method
- `LOAD-MOUSE-POINTER()` method
- `LOAD-SMALL-ICON()` method
- `MOVE-TO-BOTTOM()` method
- `MOVE-TO-TOP()` method
In character user interfaces, you can have only one window (the default window).

Certain manipulations of a parent window have a default effect on its child windows and their descendants. You cannot modify the following effects:

- Iconifying a window (triggered by a WINDOW-MINIMIZED event or by setting the WINDOW-STATE attribute to WINDOW-MINIMIZED) causes any of its descendant windows that are not already iconified to be hidden. Any child windows that are already iconified remain iconified along with their parents. Restoring the parent window (triggered by a WINDOW-RESTORED event) causes all of its descendant windows to receive a WINDOW-RESTORED event, restoring them to their visual state prior to the parent window being minimized.

- When a window receives a WINDOW-MINIMIZED event, all of its descendant windows receive WINDOW-MINIMIZED events. When a window receives a WINDOW-RESTORED event, all of its descendant windows receive WINDOW-RESTORED events.

- Applying a WINDOW-CLOSE event to a window causes all of its descendant windows to receive a PARENT-WINDOW-CLOSE event. However, any ancestor windows remain unaffected.

A WINDOW-MINIMIZED or WINDOW-RESTORED event applied to a child window has no effect on its parent or ancestor windows.

Resizing or changing the position of a window has no effect on the size or position of any descendants or ancestors of that window.

The following attributes have the Unknown value (?) until the window is realized:

- FULL-HEIGHT-CHARS attribute
- FULL-HEIGHT-PIXELS attribute
- FULL-WIDTH-CHARS attribute
- FULL-WIDTH-PIXELS attribute

If you embed the window in an OpenEdge .NET form, by setting the form’s EmbeddedWindow property to the ABL window handle, some attributes and methods of the window are either ignored or change function. For more information, see the EmbeddedWindow property reference entry.

See also CREATE widget statement, DIALOG-BOX widget
Handle Reference

This section contains reference entries that describe the ABL handle-based objects (other than widgets). Handle-based objects represent built-in object types in ABL that you can reference using object handles.

These objects include widgets, which encapsulate user interface capabilities, and other object types that provide access to a variety of ABL session capabilities. Object handles are essentially addresses that provide access to handle-based objects in memory. These handles allow you to access attributes and methods that ABL defines for each object that you can use to interact with an object’s state and behavior.

Note: Handle-based objects are conceptually analogous to but different from class-based objects. The types and capabilities of handle-based objects are defined entirely by ABL. However class-based objects represent instances of classes whose capabilities you can define as user-defined data types. For more information on class-based objects, see the CLASS statement reference entry.

You can define static or create dynamic instances of many handle-based object types using appropriate DEFINE and CREATE statements. You can reference a static instance by the defined object name or its handle, and you can reference a dynamic instance only by its handle. ABL also automatically creates instances of certain other handle-based object types in various ways, including system objects that you can access using an appropriate keyword-defined system handle.

Thus, ABL makes object handles available in two ways:

- Directly, as system handle values. A system handle is an ABL keyword that evaluates to an object handle whose object type is implied by the keyword. For example, the CURRENT-WINDOW system handle is a handle to a particular window widget. To access the attributes and methods of a system handle, you can use the keyword directly, or you can assign the keyword value to a HANDLE variable and use the variable to reference the attributes and methods:
Indirectly, as values output from various CREATE and other ABL statements, including other handle attributes and methods. You can access the attributes and methods of any object by assigning its handle to a HANDLE variable, which can hold handle values of any type. You can then use this variable to reference the attributes and methods of the object:

```abla
DEFINE VARIABLE hHandle AS HANDLE NO-UNDO.

hHandle = THIS-PROCEDURE.       /* Procedure object handle */
DISPLAY THIS-PROCEDURE:GET-SIGNATURE("").  /* Displays the same */
DISPLAY hHandle:GET-SIGNATURE("").  /* Signature as this statement. */
```

The reference entries throughout this section include both system handles and handles for object types not necessarily referenced using system handles. Each system handle is listed by its keyword (all upper case, for example: SESSION system handle), and each handle for other object types is listed by its object type (upper and lower case, for example: Server object handle).

Each entry lists the attributes and methods supported by the handle or refers you to a more general entry with the same list. For example, the attributes and methods of the CURRENT-WINDOW system handle appear under the WINDOW widget entry. Widgets share a common set of user interface capabilities as well as capabilities unique to each widget type. For a list of the attributes and methods supported by each widget, see the “Widget Reference” section on page 1143.

For more information on how to use the list attributes and methods for all handle-based object types, see the “Handle Attributes and Methods Reference” section on page 1271, which includes a complete reference entry for each attribute and method.

**Note:** You may consider an object handle to be supported for all interfaces, on all operating systems, and for SpeedScript unless otherwise indicated in the reference entry.

The following descriptions refer to both compile-time and run-time behavior, features that the language generally supports and determines at compile time and actions directed by using these features at run time. When describing compile-time features or actions, this section references ABL or the ABL compiler. When describing ABL-directed actions taken at run time, this section references the ABL Virtual Machine (AVM).

### ACTIVE-WINDOW system handle

A handle to the last ABL application window to receive an ENTRY event. You cannot set the ACTIVE-WINDOW handle, but you can read and write values for the attributes of the ACTIVE-WINDOW.
Asynchronous request object handle

Maintains the status of an asynchronous request running on an AppServer or Web service.

Syntax

```
async-request-handle [ : attribute ]
```

**async-request-handle**

A handle variable that references an asynchronous request object. This object is instantiated when you execute an asynchronous remote procedure using the RUN statement specified with the ASYNCHRONOUS option. You can get the handle value by doing one of the following:

- Use the ASYNCHRONOUS SET option on the same RUN statement that instantiates the asynchronous request.

- Reference the LAST-ASYNC-REQUEST attribute on the server handle for the AppServer where the request is running. To ensure that you are referencing a specific request, you must reference the attribute after the associated RUN statement executes and before you instantiate another asynchronous request on the same AppServer connection.

- You can also locate the asynchronous request handle by walking the chain between the FIRST-ASYNC-REQUEST and LAST-ASYNC-REQUEST attributes of the

**Notes**

- In a character interface, the ACTIVE-WINDOW, CURRENT-WINDOW, and DEFAULT-WINDOW handles return the handle of the static window for the current ABL session.

- The initial value of the ACTIVE-WINDOW handle is the CURRENT-WINDOW handle.

- The ACTIVE-WINDOW handle monitors the active window in the ABL session only. It does not monitor the active window for the window system. Accessing a non-ABL window does not affect the state of the ACTIVE-WINDOW handle.

- You can enable or disable the current window by changing ACTIVE-WINDOW:SENSITIVE.

- You can set the menu bar for the active window by assigning the handle of a menu bar to ACTIVE-WINDOW:MENUBAR.

**See also**

CURRENT-WINDOW system handle, DEFAULT-WINDOW system handle

**Syntax**

```
ACTIVE-WINDOW [ : attribute ]
```

**attribute**

An attribute of the ACTIVE-WINDOW.

**Attributes**

The ACTIVE-WINDOW handle has all the attributes of a window widget.

**Notes**

- In a character interface, the ACTIVE-WINDOW, CURRENT-WINDOW, and DEFAULT-WINDOW handles return the handle of the static window for the current ABL session.

- The initial value of the ACTIVE-WINDOW handle is the CURRENT-WINDOW handle.

- The ACTIVE-WINDOW handle monitors the active window in the ABL session only. It does not monitor the active window for the window system. Accessing a non-ABL window does not affect the state of the ACTIVE-WINDOW handle.

- You can enable or disable the current window by changing ACTIVE-WINDOW:SENSITIVE.

- You can set the menu bar for the active window by assigning the handle of a menu bar to ACTIVE-WINDOW:MENUBAR.

**See also**

CURRENT-WINDOW system handle, DEFAULT-WINDOW system handle
associated server handle. Search on the PROCEDURE-NAME attribute of each request handle to identify the specific request.

**attribute**

An attribute of the asynchronous request handle.

</tbody>
</table>

**Events**

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCEDURE-COMPLETE</td>
<td>–</td>
</tr>
</tbody>
</table>

**Notes**

- When the AppServer completes and returns the results of the asynchronous request associated with this handle, the client application that executed the request receives the PROCEDURE-COMPLETE event. This event triggers execution of the associated event procedure (if specified) in the context of an I/O blocking statement, such as the WAIT-FOR statement, UPDATE statement, or a PROCESS EVENTS statement.

- You can access this handle anywhere in the client application that executes the associated request. However, it is especially useful for reference in the event procedure for the asynchronous request. In the associated event procedure, you can access this handle as the value of the SELF system handle.

- For more information on asynchronous requests, the PROCEDURE-COMPLETE event, and asynchronous request handles, see *OpenEdge Application Server: Developing AppServer Applications*.

---

**AUDIT-CONTROL system handle**

A handle to the audit control settings for managing application auditing context and events for the current ABL session.

**Syntax**

AUDIT-CONTROL [ :attribute | :method ]
attribute

An attribute of the AUDIT-CONTROL system handle.

method

A method of the AUDIT-CONTROL system handle.

AUDIT-CONTROL system handle, AUDIT-ENABLED function, Client-principal object handle, SECURITY-POLICY system handle
Buffer object handle

A handle to a buffer object, corresponding to an underlying ABL buffer, which can be static or dynamic. An example of a static underlying buffer is one you define at compile time by using the DEFINE BUFFER statement, or by implicitly referencing a table in an ABL construct such as "Customer.CustNum". An example of a dynamic underlying buffer is one you create at run time with the CREATE BUFFER statement.

Syntax

```
buffer-handle [ :attribute | :method ]
```

**buffer-handle**

An item of type HANDLE representing a handle to a buffer object.

**attribute**

An attribute of the buffer object.

**method**

A method of the buffer object.

Buffer-field object handle

A handle to a buffer-field object. Buffer-field objects let you examine and modify the fields of a record. They also let you examine the schema properties of the field.

Syntax

```
buffer-field-handle [ :attribute ]
```

**buffer-field-handle**

A handle to a buffer-field object.

**attribute**

An attribute of the buffer-field object.
Call object handle

Buffer object handle, Query object handle

Call object handle

A handle to a call object allows you to do the following dynamically:

- Invoke an external procedure, internal procedure, or user-defined function
- Invoke a Windows DLL routine or Unix shared library routine
- Get or set an object handle attribute
- Run an object handle method

Syntax

```
call-object-handle [ :attribute | :method ]
```

call-object-handle

The handle to a call object.

attribute

An attribute of the call object.
**Call object handle**

*method*

A method of the call object. The methods let you set parameters, reset attributes to their default values, and invoke the call object.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASYNCHRONOUS</td>
<td>ASYNC-REQUEST-HANDLE</td>
</tr>
<tr>
<td>CALL-TYPE</td>

<tr>
<td>NUM-PARAMETERS</td>
<td>ORDINAL</td>
</tr>
<tr>
<td>RETURN-VALUE</td>
<td>RETURN-VALUE-DATA-TYPE</td>
</tr>
<tr>
<td>SERVER</td>
<td>TYPE</td>
</tr>
</tbody>
</table>

**Methods**

- CLEAR() method (Handle)
- INVOKE() method (Handle)
- SET-PARAMETER() method (Handle)

**Examples**

The following fragment dynamically invokes an external procedure non-persistently:

```plaintext
DEFINE VARIABLE hCall AS HANDLE NO-UNDO.
CREATE CALL hCall.

/* Invoke hello.p non-persistently */
hCall:CALL-NAME = "hello.p".
hCall:NUM-PARAMETERS = 1.
hCall:SET-PARAMETER(1, "CHARACTER", "INPUT", "HELLO WORLD").
hCall:INVOKE.

/* Clean up */
DELETE OBJECT hCall.
```

The following fragment dynamically invokes an external procedure persistently, then dynamically invokes one of its internal procedures:
The following fragment uses a single call object handle multiple times:

```plaintext
DEFINE VARIABLE hCall AS HANDLE NO-UNDO.
CREATE CALL hCall.
/* Invoke persis.p persistently */
hCall:CALL-NAME = "persis.p".
hCall:PERSISTENT = TRUE.
/* IN-HANDLE automatically set to the handle of the persistent procedure */
hCall:INVOKE.
/* Invoke internal-persis-proc in persis.p */
hCall:CALL-NAME = "internal-persis-proc".
hCall:NUM-PARAMETERS = 1.
hCall:SET-PARAMETER(1, "INTEGER", "INPUT", 333).
hCall:INVOKE.
/* Clean up */
DELETE PROCEDURE hCall:IN-HANDLE.
DELETE OBJECT hCall.
```

The following fragment gets an attribute:

```plaintext
DEFINE VARIABLE hCall AS HANDLE NO-UNDO.
CREATE CALL hCall.
/* Invoke hello.p non-persistently */
ASSIGN
  hCall:CALL-NAME = "hello.p"
  hCall:NUM-PARAMETERS = 1.
hCall:SET-PARAMETER(1, "CHARACTER", "INPUT", "HELLO WORLD").
hCall:INVOKE.
/* Reset the call object handle */
hCall:CLEAR.
/* Invoke persis.p persistently */
ASSIGN
  hCall:CALL-NAME = "persis.p"
  hCall:PERSISTENT = TRUE.
/* IN-HANDLE automatically set to the handle of the persistent procedure */
hCall:INVOKE.
/* Invoke internal-persis-proc in persis.p */
ASSIGN
  hCall:CALL-NAME = "internal-persis-proc"
  hCall:NUM-PARAMETERS = 1.
hCall:SET-PARAMETER(1, "INTEGER", "INPUT", 333).
hCall:INVOKE.
/* Clean up */
DELETE PROCEDURE hCall:IN-HANDLE.
DELETE OBJECT hCall.
```
/* Get title of frame */
ASSIGN
  hCall:IN-HANDLE = myframe_handle
  hCall:CALL-TYPE = GET-ATTR-CALL-TYPE
  hCall:CALL-NAME = "TITLE".

hCall:INVOKE.
Mytitle = hCall:RETURN-VALUE.

The following fragment sets an attribute:

/* Set SESSION:NUMERIC-FORMAT to "european" */
ASSIGN
  hCall:IN-HANDLE = "session"
  hCall:CALL-TYPE = SET-ATTR-CALL-TYPE
  hCall:CALL-NAME = "numeric-format"
  hCall:NUM-PARAMETERS = 1.

  hCall:SET-PARAMETER( 1, "CHAR", "INPUT", "european").
  hCall:INVOKE.

The following fragment drives the call object's INVOKE( ) method from a TEMP-TABLE:

/* Suppose hRuntt is a temp-table that has one record with the following fields:
parm_1
parm_2
...
parm_n
run-name
nparms
datatypes, extent nparms
iOmodes, extent nparms */
DEFINE INPUT PARAMETER TABLE-HANDLE hRuntt.
DEFINE VARIABLE hDtypes AS HANDLE NO-UNDO.
DEFINE VARIABLE hIOmodes AS HANDLE NO-UNDO.
DEFINE VARIABLE hCall AS HANDLE NO-UNDO.
DEFINE VARIABLE ix AS INTEGER NO-UNDO.

ASSIGN
  hDtypes = hRuntt:BUFFER-FIELD("datatypes")
  hIOmodes = hRuntt:BUFFER-FIELD("iOmodes").

hRuntt:FIND-FIRST.

CREATE CALL hCall.

ASSIGN
  hCall:CALL-NAME = hRuntt:BUFFER-FIELD("run-name"):BUFFER-VALUE
  hCall:NUM-PARAMETERS = hRuntt:BUFFER-FIELD("nparms"):BUFFER-VALUE.

FOR ix = 1 to hCall:NUM-PARAMETERS.
  hCall:SET-PARAMETER(ix, hDtypes:BUFFER-VALUE(ix),
END.

hCall:INVOKE.
DELETE OBJECT hCall.

/* If there are output parms, get values from hRuntt:BUFFER-FIELD(ix) */
The following fragment implements an ABL function, `sleep`, which causes the AVM to sleep for a specified number of milliseconds:

```
FUNCTION sleep RETURNS INTEGER (INPUT msecs AS INTEGER):
    DEFINE VARIABLE cFunction AS CHARACTER NO-UNDO INITIAL "sleep".
    DEFINE VARIABLE cLibrary  AS CHARACTER NO-UNDO INITIAL "libc.so.1".
    DEFINE VARIABLE hCall  AS HANDLE NO-UNDO.

    CREATE CALL hCall.
    ASSIGN
        cLibrary = "kernel32.dll" WHEN OPSYS = "WIN32"
        cFunction = "Sleep" WHEN OPSYS = "WIN32"
        hCall:CALL-NAME = cFunction
        hCall:LIBRARY  = cLibrary
        hCall:CALL-TYPE  = DLL-CALL-TYPE
        hCall:NUM-PARAMETERS = 1.

        hCall:SET-PARAMETER(1, "LONG", "INPUT", msecs).
    hCall:INVOKE( ).
    DELETE OBJECT hCall.
    RETURN msecs.
END FUNCTION.
```

Note that the code checks to determine on which OS it is running, and invokes the appropriate Windows DLL or UNIX shared library.

**Notes**

- Invoking logic dynamically requires many more lines of code and is less efficient than invoking it statically. You typically use the call object when you cannot use the RUN statement, the DYNAMIC-FUNCTION() function, or `widget:attribute` or `widget:method` syntax, as in the following situations:

  - To invoke an internal or external procedure whose **calling sequence** (number of parameters and the data type of each) is unknown at compile time.

  **Note:** If only the **name** of the procedure is unknown at compile time, use the RUN statement with the VALUE option—and avoid the call object altogether.

  - To invoke a function whose calling sequence is unknown at compile time.

  **Note:** If only the **name** of the function is unknown at compile time, use the DYNAMIC-FUNCTION() function—and avoid the call object altogether.

  - To reference a widget attribute or method whose name is unknown at compile time.

  - To invoke a Windows DLL routine or Unix shared library routine when:

    - The number of parameters and their data type is only known at run time
    - The routine exists in both a Windows DLL and a Unix shared library
    - The routine has a variable number of parameters

If you already know the name of the attribute or procedure, you know its syntax, since the name implies certain syntax. And if you know the syntax, you know the calling sequence, since the syntax defines the calling sequence. And if you know the calling sequence, you
can use \textit{widget:attribute} or \textit{widget:method} syntax—and avoid the call object altogether.

- To create a call object, use the following syntax:

  \textbf{Syntax}

  \begin{verbatim}
  CREATE object-handle [ IN widget-pool ]
  \end{verbatim}

  For example:

  \begin{verbatim}
  CREATE CALL hCall.
  \end{verbatim}

  \textbf{Note:} Unlike most ABL objects, the call object, by default, goes into the SESSION widget pool, not into the closest unnamed widget pool.

- To delete a call object, use the following syntax:

  \textbf{Syntax}

  \begin{verbatim}
  DELETE OBJECT handle.
  \end{verbatim}

  For example:

  \begin{verbatim}
  DELETE OBJECT hCall.
  \end{verbatim}

  Since the call object, by default, goes into the SESSION widget pool, not into the closest unnamed widget pool, to delete a call object created when the IN widget-pool option is not used, use the \texttt{DELETE object handle} syntax explicitly.

  \textbf{See also} \hspace{5em} \texttt{RUN statement}

\section*{Client-principal object handle}

A handle to a Client-principal object. Each Client-principal object instance contains information specific to one user login session. This login session may be used as an application or database user identity from an authentication domain registered in a trusted authentication domain registry. You create an instance of a Client-principal object at run time using the \texttt{CREATE CLIENT-PRINCIPAL} statement.

\textbf{Note:} You use a Client-principal object with the \texttt{SET-CLIENT( )} method or \texttt{SET-DB-CLIENT} function to set the user identity for an ABL session or OpenEdge database. You can have only one active Client-principal object set as the current user at any one point in time for a session or database connection.
Client-principal object handle

Syntax

```
client-principal-handle [ :attribute | :method ]
```

`client-principal-handle`

A variable of type HANDLE that references a Client-principal object.

`attribute`

An attribute of the Client-principal object handle.

`method`

A method of the Client-principal object handle.

AUDIT-CONTROL system handle, AUDIT-POLICY system handle, CREATE CLIENT-PRINCIPAL statement, SECURITY-POLICY system handle, SET-CLIENT( ) method, SETUSERID function, SET-DB-CLIENT function
A handle to the system clipboard widget. The CLIPBOARD handle allows you to implement interactions that allow the user to transfer data between ABL field-level widgets, or between ABL field-level widgets and the widgets of other applications running on the system. ABL can interpret the data read from or written to the system clipboard widget as a single item or as a group of multiple items. These data transfers are typically invoked as cut, copy, and paste operations.

### Syntax

```plaintext
CLIPBOARD [ :attribute ]
```

**attribute**

An attribute of the clipboard widget.

### Examples

The following code fragment implements cut, copy, and paste operations for the EM_Cut, EM_Copy, and EM_Paste items on the EditMenu menu. It uses the FOCUS handle to reference the widget that has the current input focus.

Note that the fragment tests the widget type of the FOCUS widget in two instances: once when EditMenu is opened during the MENU-DROP event to determine what clipboard operations are valid for the widget, and once again when a clipboard operation is chosen from the menu to determine how the operation is executed for the widget. During the MENU-DROP event, if a particular operation is valid for the FOCUS widget the menu item for that operation is enabled. Otherwise, it is disabled.

During the CHOOSE event for an enabled menu item, the fragment executes the corresponding clipboard operation in a way that accounts for the unique features of the FOCUS widget. For example, the copy operation (EM_Copy) copies the selected text from an editor widget, copies the label text from a radio set item, and copies a composed true or false message for a toggle box. Your own implementation of these operations for the same widgets can be quite different.

For a complete description of this example, see the chapter on the system clipboard in *OpenEdge Development: Programming Interfaces*. 
DEFINE VARIABLE tStat AS LOGICAL NO-UNDO.

... ON MENU-DROP OF MENU EditMenu DO:
   IF FOCUS:TYPE = "EDITOR" THEN DO:
      MENU-ITEM EM_Cut:SENSITIVE IN MENU EditMenu =
         IF LENGTH(FOCUS:SELECTION-TEXT) > 0 THEN TRUE ELSE FALSE.
      MENU-ITEM Em_Copy:SENSITIVE IN MENU EditMenu =
         IF LENGTH(FOCUS:SELECTION-TEXT) > 0 THEN TRUE ELSE FALSE.
      MENU-ITEM EM_Paste:SENSITIVE IN MENU EditMenu =
         IF CLIPBOARD:NUM-FORMATS > 0 THEN TRUE ELSE FALSE.
   END.
   ELSE IF FOCUS:TYPE = "RADIO-SET" OR
      FOCUS:TYPE = "SELECTION-LIST" OR
      FOCUS:TYPE = "SLIDER" OR
      FOCUS:TYPE = "TOGGLE-BOX" THEN DO:
         MENU-ITEM EM_Cut:SENSITIVE IN MENU EditMenu = FALSE.
         MENU-ITEM Em_Copy:SENSITIVE IN MENU EditMenu = TRUE.
         MENU-ITEM EM_Paste:SENSITIVE IN MENU EditMenu = FALSE.
   END.
   ELSE IF FOCUS:TYPE = "FILL-IN" THEN DO:
      MENU-ITEM EM_Cut:SENSITIVE IN MENU EditMenu =
         IF LENGTH(FOCUS:SCREEN-VALUE) > 0 THEN TRUE ELSE FALSE.
      MENU-ITEM Em_Copy:SENSITIVE IN MENU EditMenu =
         IF LENGTH(FOCUS:SCREEN-VALUE) > 0 THEN TRUE ELSE FALSE.
      MENU-ITEM EM_Paste:SENSITIVE IN MENU EditMenu =
         IF CLIPBOARD:NUM-FORMATS > 0 THEN TRUE ELSE FALSE.
   END.
   ELSE DO:
      MENU-ITEM EM_Cut:SENSITIVE IN MENU EditMenu = FALSE.
      MENU-ITEM Em_Copy:SENSITIVE IN MENU EditMenu = FALSE.
      MENU-ITEM EM_Paste:SENSITIVE IN MENU EditMenu = FALSE.
   END.
END. /* ON MENU-DROP IN EditMenu */
The following r-clpmul.p procedure demonstrates interaction with the clipboard using multiple items. The procedure copies out four rows of five numbers to the clipboard. It first displays the clipboard data as a single item, and then as a list of multiple items.

As a further demonstration of how the CLIPBOARD handle works with multiple items, try the following experiment:

1. Run the procedure, and at the pause, paste the result into an edit tool in your window system, such as Notepad in Windows.

2. You may have to select and copy text in the edit tool to activate the system clipboard before running the procedure.

3. Modify the text in the edit tool, leaving at least one tab or newline character, and copy it back to the clipboard from the edit tool.

4. Respond to the pause in the procedure to see how the modified clipboard data is displayed.
In character mode environments where there is no system clipboard, ABL supports CLIPBOARD handle operations within a single ABL application. You can cut and paste among fields in one ABL application, but not between one ABL application and another ABL or non-ABL application.

In graphical window systems, ABL supports CLIPBOARD handle operations using the system clipboard. This allows data transfers among ABL and non-ABL applications as well as within a single ABL application.

The AVAILABLE-FORMATS attribute returns a comma-separated string containing the names of the available formats for the data stored in the clipboard. ABL currently supports two formats:

- **PRO_TEXT** — Specifies the standard text format on your system (CF_TEXT in Windows).
- **PRO_MULTIPLE** — Specifies that the data in the clipboard contains tab or newline characters, and thus can be read as multiple items.

The ITEMS-PER-ROW attribute specifies how the AVM writes multiple items to the clipboard. Set the MULTIPLE attribute to TRUE before specifying ITEMS-PER-ROW. Then when you set ITEMS-PER-ROW to any integer value \( n \) greater than 1, the AVM terminates every \( n \)th value you assign to the VALUE attribute with a newline character and

```
/* Copy rows of integer items to the clipboard, display the clipboard value. */
ASSIGN
   CLIPBOARD:_MULTIPLE = TRUE
   CLIPBOARD:ITEMS-PER-ROW = 5.
REPEAT ix = 1 TO 20:
   CLIPBOARD:VALUE = STRING(ix).
END.
ASSIGN
   CLIPBOARD:_MULTIPLE = FALSE
   ClipBuffer = CLIPBOARD:VALUE.
ENABLE ClipBuffer WITH FRAME A.
DISPLAY SPACE(1) ClipBuffer LABEL "Clipboard Data" WITH FRAME A.
PAUSE.

/* Display each item of the clipboard value. */
ASSIGN
   CLIPBOARD:MULTIPLE = TRUE
   ClipItem = "".
REPEAT WHILE ClipItem <> ?:
   ClipItem = CLIPBOARD:VALUE.
   IF ClipItem <> ? THEN
      DISPLAY SPACE(1) ClipItem FORMAT "x(16)" LABEL "Clipboard Item"
      WITH DOWN FRAME B.
   END.
   CLIPBOARD:MULTIPLE = FALSE.
```
terminates all other values with a tab character. This formats the output in the clipboard into newline-terminated rows of \( n \) items separated by tabs. The default value for the ITEMS-PER-ROW attribute is 1.

During a MULTIPLE write, you can set and reset ITEMS-PER-ROW at any time until you set the MULTIPLE attribute to FALSE. When you set the MULTIPLE attribute to FALSE, the AVM uses the current value of ITEMS-PER-ROW to format and flush the data to the clipboard, and resets the ITEMS-PER-ROW attribute to 1.

The value of ITEMS-PER-ROW has no effect when reading data from the clipboard.

- The MULTIPLE attribute specifies whether the AVM reads data from, and writes data to, the clipboard as a single item or as multiple items.

When you set MULTIPLE to FALSE, the AVM treats all data in the clipboard as a single item. Thus, any character string you assign to the VALUE attribute replaces all data in the clipboard, and whenever you read the VALUE attribute it returns all the data in the clipboard.

When you set MULTIPLE to TRUE, the AVM treats the data in the clipboard as multiple items separated by tab or newline characters.

When you set the MULTIPLE attribute to TRUE and write values to the clipboard (assign values to the VALUE attribute), the AVM stores the values in a buffer until you set MULTIPLE to FALSE. At this time the AVM assigns the values to the clipboard separated from each other by tab or newline characters according to the value of the ITEMS-PER-ROW attribute. Note that the clipboard data itself does not change until you set MULTIPLE to FALSE. When you do set MULTIPLE to FALSE, all data previously in the clipboard is replaced by the items you have written.

When you set the MULTIPLE attribute to TRUE and read values from the clipboard (assign values from the VALUE attribute), each read returns the next item in the clipboard (starting with the first one). After all items have been read, the VALUE attribute returns the Unknown value (\(?\)). Setting the MULTIPLE attribute to FALSE and then to TRUE restarts the item pointer to read the first item of data in the clipboard.

Until you (or another application) write data to the clipboard, changing the value of the MULTIPLE attribute itself has no effect on clipboard contents. It only affects the way you can access the clipboard for reading and writing.

The default value for the MULTIPLE attribute is FALSE.

- The NUM-FORMATS attribute returns the number of formats available to read data from the clipboard. If no data is in the clipboard, the value is 0. If data is in the clipboard, the value is 1 (for PRO_TEXT) unless there are tab or newline characters in the data, in which case the value is 2 (for both PRO_TEXT and PRO_MULTIPLE).

- The VALUE attribute accesses the data in the clipboard. Reading the VALUE attribute has no effect on the clipboard contents. However, the exact value read or written depends on the setting of the MULTIPLE attribute.

When the MULTIPLE attribute is FALSE, reading the VALUE attribute returns the current value in the clipboard as a single item. If there is no data in the clipboard, the VALUE attribute returns the Unknown value (?). Writing to the VALUE attribute immediately changes the current value in the clipboard to the value that is written.
When the MULTIPLE attribute is TRUE, reading the VALUE attribute either references one of the multiple data items in the clipboard, or references the Unknown value (?) if all items have been read or there is no data in the clipboard. Writing to the VALUE attribute buffers each assignment and replaces the current data in the clipboard with the multiple values assigned when the MULTIPLE attribute is set to FALSE. See the previous description of the MULTIPLE attribute for more information.

**Note:** Windows provides clipboard storage for a maximum of 64K of data.

Assigning the Unknown value (?) to the VALUE attribute has no effect. To write a null item or clear the system clipboard when writing a single item, assign the null string (""") to the VALUE attribute.

- To cut or copy an ABL data item to the clipboard, set the CLIPBOARD:VALUE attribute to the value of the appropriate field or variable. A cut or copy operation replaces all data in the clipboard with the data from the specified ABL field or variable.

- To paste data from the clipboard to an ABL data item, assign the value of the CLIPBOARD:VALUE attribute to the appropriate the field or variable. If there is no data in the clipboard, a paste operation assigns the Unknown value (?) to the data item.

- To implement clipboard operations, use the FOCUS system handle, which identifies the ABL field-level widget that has the current input focus. Depending on the type of widget (for example, EDITOR or RADIO-ITEM) and its input state, you use one of several possible widget attributes as the source or destination for the data. For example, when working with selected text in an editor widget, use the SELECTION-TEXT attribute to cut or copy and the REPLACE-SELECTION-TEXT method to paste, but when working with the value of the entire editor field, use the SCREEN-VALUE attribute for all operations.

- Do not interrupt an ABL clipboard operation with input blocking statements like UPDATE or WAIT-FOR. In general, make any ABL clipboard cut, copy, or paste operation with the CLIPBOARD handle a one-step operation. Any interruption gives the user an opportunity to access and modify the clipboard from outside ABL, in the middle of the ABL clipboard operation.

- Windows provides default clipboard operations through control keys, whether or not you implement them with the CLIPBOARD handle. These operations are available in editor and fill-in widgets, and are completely compatible with CLIPBOARD handle operations. They are single-item operations without any interaction with the MULTIPLE attribute. They also can occur in the middle of an ABL clipboard operation, if it is interrupted. (See the previous bullet on interrupting ABL clipboard operations.) The operations and control keys to activate them include:
  - **Cut** — `CTRL+X` and `SHIFT+DEL`
  - **Copy** — `CTRL+C` and `CTRL+INS`
  - **Paste** — `CTRL+V` and `SHIFT+INS`

- The TYPE attribute returns the widget type, PSEUDO-WIDGET.
• For more information on implementing clipboard operations with the CLIPBOARD handle, see *OpenEdge Development: Programming Interfaces*.

FOCUS system handle

---

**CODEBASE-LOCATOR system handle**  
(Windows only; Graphical interfaces only)

A handle to the CODEBASE-LOCATOR object. A CODEBASE-LOCATOR object specifies the location and authentication information for a client application’s codebase (that is, an application’s files) stored on an AppServer or a web server. This object allows the WebClient to access application files for download. It also allows WebClient and the client application to share authentication information.

**Note:** Does not apply to SpeedScript programming.

### Syntax

```
CODEBASE-LOCATOR [ :attribute ]
```

**attribute**

Specifies an attribute of the CODEBASE-LOCATOR handle.

### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Attribute</th>
<th>Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPSERVER-INFO</td>
<td>APPSERVER-PASSWORD</td>
<td>APPSERVER-USERID</td>
</tr>
<tr>
<td>END-USER-PROMPT</td>
<td>HANDLE</td>
<td>INSTANTIATING-PROCEDURE</td>
</tr>
<tr>
<td>KEEP-CONNECTION-OPEN</td>
<td>KEEP-SECURITY-CACHE</td>
<td>LOCATOR-TYPE</td>
</tr>
<tr>
<td>NECESSARY-PROMPT</td>
<td>NEEDS-PROMPT</td>
<td>PERSISTENT-CACHE-DISABLED</td>
</tr>
<tr>
<td>SERVER</td>
<td>TYPE</td>
<td>URL</td>
</tr>
<tr>
<td>URL-PASSWORD</td>
<td>URL-USERID</td>
<td></td>
</tr>
</tbody>
</table>

### Notes

• The CODEBASE-LOCATOR handle applies only to WebClient.

• The following attributes represent the security cache: APPSERVER-INFO, APPSERVER-PASSWORD, APPSERVER-USERID, URL-PASSWORD, URL-USERID, and KEEP-SECURITY-CACHE. These attributes are readable and writable.

• WebClient sets the following read-only attributes based on values stored in the application configuration (.ProwcApp) file: END-USER-PROMPT, KEEP-CONNECTION-OPEN, LOCATOR-TYPE, NECESSARY-PROMPT, NECESSARY-PROMPT, PERSISTENT-CACHE-DISABLED, and URL.
• Valid URL protocols depend on the LOCATOR-TYPE. If LOCATOR-TYPE is "AppServer", valid URL protocols include: HTTP, HTTPS, and AppServer. If LOCATOR-TYPE is "InternetServer", valid URL protocols include: HTTP, HTTPS, and FILE.

• The TYPE attribute returns the widget type, PSEUDO-WIDGET.

See also CONNECT( ) method (AppServer)

COLOR-TABLE system handle
(Windows only; Graphical interfaces only)

A handle to the current color table.

Note: Does not apply to SpeedScript programming.

Syntax

```
COLOR-TABLE [ :attribute | :method ]
```

attribute

An attribute of the COLOR-TABLE handle.

method

A method of the COLOR-TABLE handle.

Attributes

<table>
<thead>
<tr>
<th>HANDLE attribute</th>
<th>INSTANTIATING-PROCE DURE attribute</th>
<th>NUM-ENTRIES attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE attribute</td>
<td>--</td>
<td>--</td>
</tr>
</tbody>
</table>

Methods

<table>
<thead>
<tr>
<th>GET-BLUE-VALUE( ) method</th>
<th>GET-DYNAMIC( ) method</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET-GREEN-VALUE( ) method</td>
<td>GET-RED-VALUE( ) method</td>
</tr>
<tr>
<td>GET-RGB-VALUE( ) method</td>
<td>SET-BLUE-VALUE( ) method</td>
</tr>
<tr>
<td>SET-DYNAMIC( ) method</td>
<td>SET-GREEN-VALUE( ) method</td>
</tr>
<tr>
<td>SET-RED-VALUE( ) method</td>
<td>SET-RGB-VALUE( ) method</td>
</tr>
</tbody>
</table>

Example

This procedure sets the number of entries in the color table, makes color ix + 1 dynamic, then sets the red, green, and blue values for this entry:
1212

Note:
In this procedure, you can replace the SET-RED-VALUE(), SET-GREEN-VALUE(), and SET-BLUE-VALUE() methods with the SET-RGB-VALUE() method as follows:
COLOR-TABLE:SET-RGB-VALUE(ix, RGB-VALUE(red, green, blue)).

Notes

- The current color table is the color table in the startup environment or the environment most recently specified in a USE statement.

- To determine the number of entries in the color table, access the NUM-ENTRIES attribute. For character interfaces, the value of this attribute is zero.

- To change the number of entries in the color table, modify the NUM-ENTRIES attribute.

- To let users modify color table entries at run time, display the System Color dialog box by coding the SYSTEM-DIALOG COLOR statement.

- To specify a red, green, or blue value for a dynamic color, supply an integer expression that returns a value between 0 and 255 inclusive.

- To save a color definition from the color table to the current environment, use the PUT-KEY-VALUE statement. To retrieve a color definition from the current environment, use the GET-KEY-VALUE statement.

- The value of COLOR-TABLE:TYPE is “PSEUDO-WIDGET.”

- The SET-RGB-VALUE() and GET-RGB-VALUE() methods can be used as an alternative to specifying each individual red, green, and blue color value with the individual SET-RED-VALUE(), SET-GREEN-VALUE(), SET-BLUE-VALUE() methods, and GET-RED-VALUE(), GET-GREEN-VALUE(), and GET-BLUE-VALUE() methods, respectively.

- The SET-RGB-VALUE() and GET-RGB-VALUE() methods to set or retrieve colors are primarily used for Active X controls.
• The index is zero based. For example, the statement \texttt{COLOR-TABLE:GET-BLUE-VALUE(2)} returns the color of the 3rd entry.

\textbf{See also} \texttt{GET-KEY-VALUE} statement, \texttt{PUT-KEY-VALUE} statement, \texttt{SYSTEM-DIALOG COLOR} statement, \texttt{USE} statement

\section*{COM-SELF system handle (Windows only)}

A component handle to the ActiveX object (ActiveX control or ActiveX automation object) that generated the event being handled by the currently executing ActiveX event procedure.

\textbf{Note:} Does not apply to SpeedScript programming.

\section*{Syntax}

\begin{verbatim}
COM-SELF [ :0CX-property-reference | :0CX-method-reference ]
\end{verbatim}

\textit{0CX-property-reference | 0CX-method-reference}

A reference to a valid property or method associated with the ActiveX control.

\section*{Example}

The following code fragment displays the name and position of the ActiveX control that generates a Click event:

\begin{verbatim}
PROCEDURE ANYWHERE.Click:
  MESSAGE "Clicked control" COM-SELF:Name "at X-position" COM-SELF:Left
  "and Y-position" COM-SELF:Top VIEW-AS ALERT-BOX.
END PROCEDURE.
\end{verbatim}

\section*{Notes}

• Unlike ABL widget handles that have the HANDLE data type, the component handle returned by COM-SELF has the COM-HANDLE data type.

• You can reference the COM-SELF handle only within an ActiveX control (OCX) event procedure.

• The syntax for referencing ActiveX control properties and methods extends the syntax for referencing widget attributes and methods. For more information, see the “Handle Attributes and Methods Reference” section on page 1271.

\textbf{See also} \texttt{PROCEDURE} statement, \texttt{SELF} system handle

\section*{COMPILER system handle}

A handle to information on a preceding COMPILE statement.
COMPILER system handle

Syntax

```
COMPILER [ :attribute ]
```

attribute

Specifies an attribute of the COMPILER system handle.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>CLASS-TYPE attribute</th>
<th>ERROR attribute</th>
<th>ERROR-COLUMN attribute</th>
<th>ERROR-ROW attribute</th>
<th>FILE-NAME attribute</th>
<th>FILE-OFFSET attribute</th>
<th>HANDLE attribute</th>
<th>INSTANTIATING-PROCEDURE attribute</th>
<th>MULTI-COMPILE attribute</th>
<th>NUM-MESSAGES attribute</th>
<th>STOPPED attribute</th>
<th>TYPE attribute</th>
</tr>
</thead>
</table>

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>GET-COLUMN( ) method</th>
<th>GET-ERROR-COLUMN( ) method</th>
<th>GET-ERROR-ROW( ) method</th>
<th>GET-FILE-NAME( ) method</th>
<th>GET-FILE-OFFSET( ) method</th>
<th>GET-MESSAGE( ) method (Handle)</th>
<th>GET-MESSAGE-TYPE( ) method</th>
<th>GET-NUMBER( ) method</th>
<th>GET-ROW( ) method</th>
</tr>
</thead>
</table>

Example

The input for the example procedure is a comma-separated list of source files. It compiles each of these procedures. If a compilation error occurs, an appropriate message is written to the compile.msgs file.

```
r-cmpchk.p

/* Compile a series of source files passed in a comma separated list. */
DEFINE INPUT PARAMETER sources AS CHARACTER NO-UNDO.
DEFINE VARIABLE entry-num AS INTEGER NO-UNDO.

/* If the output file already exists, delete it. If this results in an error, ignore the error. */
OS-DELETE "compile.msgs".

DO entry-num = 1 TO NUM-ENTRIES(sources):
   COMPILE VALUE(ENTRY(entry-num, sources)) SAVE.
   IF COMPILER:ERROR THEN DO:
      OUTPUT TO "compile.msgs" APPEND.
      MESSAGE "Compilation error in" COMPILER:FILE-NAME "at line"
      COMPILER:ERROR-ROW "column" COMPILER:ERROR-COL.
      OUTPUT CLOSE.
   END.
END.
```

Notes

- If a compilation is successful, the COMPILER:ERROR attribute is set to FALSE.
- After a COMPILE statement, check the COMPILER:ERROR and COMPILER:WARNING attributes to determine whether the compilation was successful.
CURRENT-WINDOW system handle

If the value of ERROR is TRUE, you can use the FILE-NAME to determine in which source file the error occurred. You can use either the ERROR-ROW and ERROR-COLUMN attributes or the FILE-OFFSET attribute to determine where in the source file an error occurred. You can use this information to compose a message to display or write to a log file. To find the specific error and warning messages, check the ERROR-STATUS handle.

- The TYPE attribute returns the widget type, PSEUDO-WIDGET.

See also COMPILE statement

CURRENT-WINDOW system handle

A handle to the default window for the current ABL session. This window is the default parent for all frames, dialog boxes, alert boxes, and messages. Set or examine the attributes of the CURRENT-WINDOW handle to modify or get information on the current default window.

Syntax

```
CURRENT-WINDOW [ :attribute ]
```

attribute

An attribute of the CURRENT-WINDOW.

Attributes

The CURRENT-WINDOW handle has all the attributes of a window widget.

Notes

- The default value of the CURRENT-WINDOW handle is the static session window referenced by the DEFAULT-WINDOW handle. You can change the default window for the current session by assigning the handle of a window to CURRENT WINDOW.
- The IN WINDOW phrase allows you to explicitly assign a window as a parent for a frame, dialog box, alert box, or message.
- In a character interface, the ACTIVE-WINDOW, CURRENT-WINDOW, and DEFAULT-WINDOW handles return the handle of the static window for the current ABL session.
- The CURRENT-WINDOW attribute of a procedure allows you to specify a default window for the procedure block. The CURRENT-WINDOW attribute of a procedure overrides the CURRENT-WINDOW handle for the procedure block.
- You can enable or disable the current window by changing CURRENT-WINDOW:SENSITIVE.
- You can set the menu bar for the current window by assigning the handle of a menu bar to CURRENT-WINDOW:MENUBAR.
- You can make the current window visible or invisible by changing the value of CURRENT-WINDOW:VISIBLE.
- Because CURRENT-WINDOW is the general default parent for ABL frames, you cannot set CURRENT-WINDOW to the handle of a .NET form’s shadow window. If allowed, this would make the associated .NET form a default parent for ABL frames, and ABL
cannot parent ABL frames to .NET forms. A .NET form’s shadow window handle is 
provided by the ProWinHandle property of the Progress.Windows.Form class, which an 
OpenEdge .NET class designed for instantiating .NET forms in an ABL session.
Therefore, any attempt to set CURRENT-WINDOW to a ProWinHandle property value 
raises a run-time error.

See also  ACTIVE-WINDOW system handle, DEFAULT-WINDOW system handle

Data-relation object handle

A handle to a data-relation object. A data-relation object defines one relation between a pair of 
parent and child buffers in a ProDataSet object that have a one-to-one or one-to-many 
parent-child relationship. A data-relation object identifies the parent and child buffers, and the 
fields in each buffer that define the primary and foreign key fields of the relation.

A data-relation object can be static or dynamic. A static data-relation object is one you define
at compile time as part of the DEFINE DATASET statement using the data-relation option. A 
dynamic data-relation object is one you create at run time for a dynamic ProDataSet object using 
the ADD-RELATION( ) method. Use this handle to access the data-relation object’s attributes.

Note:  Does not apply to SpeedScript programming.

Syntax

```plaintext
data-relation-handle [ :attribute ]
```

data-relation-handle

A handle variable that references a data-relation object.

attribute

An attribute of the data-relation object.

Attributes

<table>
<thead>
<tr>
<th>ACTIVE attribute</th>
<th>ADM-DATA attribute</th>
<th>CHILD-BUFFER attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT-QUERY( ) method</td>
<td>FOREIGN-KEY-HIDDEN attribute</td>
<td>HANDLE attribute</td>
</tr>
<tr>
<td>INSTANTIATING-PROCEDURE attribute</td>
<td>MAXIMUM-LEVEL attribute</td>
<td>NAME attribute</td>
</tr>
<tr>
<td>NESTED attribute</td>

<td>PRIVATE-DATA attribute</td>
</tr>
<tr>
<td>QUERY attribute</td>
<td>RECURSIVE attribute</td>
<td>RELATION-FIELDS attribute</td>
</tr>
<tr>
<td>REPOSITION attribute</td>
<td>TYPE attribute</td>
<td>WHERE-STRING attribute</td>
</tr>
</tbody>
</table>

Notes

- You cannot define multiple data-relation objects for the same pair of parent and child buffers.
• You cannot delete a data-relation object. When the ProDataSet object is deleted or cleared, the data-relation objects are automatically deleted.

See also ADD-RELATION( ) method, DEFINE DATASET statement

Data-source object handle

A handle to a data-source object. A data-source object supports the automatic filling of a ProDataSet object member table, as well as applying updates back to one or more database tables. There is a distinct data-source object for each member buffer, which allows a single ProDataSet object and a single FILL operation on that object to combine data from multiple databases. A data-source object is defined independently of any ProDataSet object.

A data-source object can be static or dynamic. A static data-source object is one you define at compile time with the DEFINE DATA-SOURCE statement. A dynamic data-source object is one you create at run time with the CREATE DATA-SOURCE statement. Use this handle to access the data-source object’s attributes and methods.

Note: Does not apply to SpeedScript programming.

Syntax

```
data-source-handle [ :attribute | :method ]
```

data-source-handle

A handle variable that references a data-source object.

attribute

An attribute of the data-source object.

method

A method of the data-source object.

Attributes

<table>
<thead>
<tr>
<th>ADM-DATA attribute</th>
<th>FILL-WHERE-STRING attribute</th>
<th>HANDLE attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>INSTANTIATING-PROCEDURE attribute</td>
<td>KEYS attribute</td>
<td>MERGE-BY-FIELD attribute</td>
</tr>
<tr>
<td>NAME attribute</td>
<td>NEXT-ROWID attribute</td>
<td>NEXT-SIBLING attribute</td>
</tr>
<tr>
<td>NUM-SOURCE-BUFFERS attribute</td>
<td>PREFER-DATASET attribute</td>
<td>PRIVATE-DATA attribute</td>
</tr>
<tr>
<td>QUERY attribute</td>
<td>RESTART-ROW attribute</td>
<td>RESTART-ROWID attribute</td>
</tr>
<tr>
<td>SAVE-WHERE-STRING attribute</td>
<td>TYPE attribute</td>
<td>–</td>
</tr>
</tbody>
</table>
### Methods

<table>
<thead>
<tr>
<th>ADD-SOURCE-BUFFER( ) method</th>
<th>GET-DATASET-BUFFER( ) method</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET-SOURCE-BUFFER( ) method</td>
<td></td>
</tr>
</tbody>
</table>

### Notes

- To associate a query with a dynamic data-source object, use the QUERY attribute. To disassociate the query and data-source object, set the QUERY attribute to the Unknown value (?).
- To override the WHERE clause in the query, use the FILL-WHERE-STRING attribute.

CREATE DATA-SOURCE statement, DEFINE DATA-SOURCE statement

---

**DEBUGGER system handle**

A handle that lets ABL procedures initialize and control the Application Debugger.

To use the DEBUGGER handle, you must have the Application Debugger installed in your OpenEdge environment.

**Note:** Does not apply to SpeedScript programming.

#### Syntax

```
DEBUGGER [ :attribute | :method ]
```

- **attribute**
  
  Specifies an attribute of the DEBUGGER handle.

- **method**

  Specifies a method of the DEBUGGER handle.

#### Attributes

<table>
<thead>
<tr>
<th>HANDLE attribute</th>
<th>INSTANTIATING-PROCEDURE attribute</th>
<th>TYPE attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>VISIBLE attribute</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Methods

<table>
<thead>
<tr>
<th>CANCEL-BREAK( ) method</th>
<th>CLEAR( ) method (Handle)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG( ) method</td>
<td>DISPLAY-MESSAGE( ) method</td>
</tr>
<tr>
<td>INITIATE( ) method</td>
<td>SET-BREAK( ) method</td>
</tr>
</tbody>
</table>
Examples

The following example displays Orders for each Customer in the Sports2000 database using two procedure files. The r-cusbug.p file initializes the Debugger and sets a breakpoint at line 6 of the r-ordbug.p file. Thus, each time r-ordbug.p displays an Order, the Debugger takes control before it displays the Order Lines. Just before completing execution, r-cusbug.p clears the debugging session before returning.

r-cusbug.p

```
DEFINE NEW SHARED BUFFER CustBuf FOR Customer.
DEFINE VARIABLE debug AS LOGICAL NO-UNDO.
d Debug = DEBUGGER:INITIATE().
FOR EACH CustBuf NO-LOCK:
  IF CAN-FIND(Order OF CustBuf) THEN
    RUN r-ordbug.p.
  END.
END.
Debug = DEBUGGER:CLEAR().
```

r-ordbug.p

```
DEFINE SHARED BUFFER CustBuf FOR Customer.

FOR EACH Order OF CustBuf NO-LOCK:
  DISPLAY CustBuf.Name CustBuf.CustNum CustBuf.City CustBuf.State
  FOR EACH OrderLine OF Order NO-LOCK, Item OF OrderLine NO-LOCK:
    DISPLAY Item.ItemName Item.ItemLum LrderLine Qty.
  END. /* FOR EACH OrderLine */
END. /* FOR EACH Order */
```

Notes

- You must initialize the Debugger using either the DEBUG( ) or INITIATE( ) method before using any of the remaining methods in a procedure.

The DEBUG( ) and INITIATE( ) methods provide separate means to invoke the Debugger, and do not depend on each other to start a debugging session. The DEBUG( ) method initializes and gives control to the Debugger whether or not the INITIATE( ) method has been executed.

- The TYPE attribute returns the widget type, PSEUDO-WIDGET.

- The VISIBLE attribute specifies whether the Debugger window is visible on the screen. When set to FALSE, if the Debugger window is currently visible, it is removed from the screen. When set to TRUE, if the Debugger window is currently invisible, it is displayed. Note that making the Debugger window visible does not, in itself, give control to the Debugger.

Note: The ABL code that initiates the Debugger and displays it on the screen is responsible for removing the Debugger from the screen when it is no longer needed by setting the VISIBLE attribute to FALSE.

- After invoking the INITIATE method, execution continues in the procedure until it encounters a breakpoint or a statement invoking the DEBUG method. If the procedure encounters a breakpoint, the Debugger takes control running in application mode (with
control over the invoking application). If the procedure invokes the DEBUG method, the Debugger takes control running in stand-alone mode (with control only over applications started from the Debugger).

- References to line numbers in internal procedures must be relative to the debug listing in which they are contained.

- When you set or cancel a breakpoint, you must distinguish between a line number value less than 1 and a value of 1 or greater. Any value for \textit{line-number} less than 1 (for example, 0 or -1) specifies the first executable line of the main \textit{procedure} in the file specified by \textit{procedure}. However, a positive value for \textit{line-number} specifies the first executable line on or after \textit{line-number} in the \textit{file} specified by \textit{procedure}. For example, suppose \textit{procedure} specifies a file like this:

```
1      DEFINE VARIABLE lStart AS LOGICAL NO-UNDO INITIAL TRUE.
2      PROCEDURE ShowStart:
3          IF lStart THEN MESSAGE "Procedure is starting ...".
4          END.
5
6      MESSAGE "Hello World!".
7      RUN ShowStart.
8      lStart = FALSE.
   ...
```

If you specify a breakpoint at line 0, -1, or any negative value, the breakpoint actually occurs at line 6, the first line that executes in the main procedure. If you specify a breakpoint at line 1 or 2, the breakpoint occurs at line 3, the first executable line in the file, which happens to be the first executable line of an internal procedure.

This distinction also affects procedures containing the Trigger phrase used to define triggers in widget definitions. For example, suppose \textit{procedure} specifies this file:

```
1      DEFINE BUTTON bOK LABEL "OK"
2      TRIGGERS:
3          ON CHOOSE
4              MESSAGE "OK Pressed!".
5          END TRIGGERS.
6      MESSAGE "Hello World!".
   ...
```

Again, if you specify a breakpoint at line -1, the breakpoint occurs on line 6, but if you specify the breakpoint at line 1, it actually occurs at line 4, which is the first executable line of a trigger block.

\textbf{Note:} You cannot set a watchpoint programmatically using the DEBUGGER system handle. A watchpoint is a form of breakpoint which tells the Debugger to interrupt program execution when the value of a variable, buffer field, or attribute reference changes.

For more information on the Debugger, its features and functions, and its modes of execution, see \textit{OpenEdge Development: Debugging and Troubleshooting}.

\textbf{See also} LOG-MANAGER system handle
DEFAULT-WINDOW system handle

A handle to the static window of the current ABL session. Every ABL session has one static window. This window displays all frames until the CURRENT-WINDOW system handle is set to the handle of another [dynamic] window or unless a displayed frame is explicitly parented to another window. Its message area also displays messages that have no other available display destination. Use the DEFAULT-WINDOW handle to set or examine the attributes of this unnamed session window.

Syntax

```
DEFAULT-WINDOW [ :attribute ]
```

attribute

An attribute of the DEFAULT-WINDOW.

Attributes

The DEFAULT-WINDOW handle has all the attributes of a window widget.

Notes

- If you display or view a frame without the IN WINDOW option and without first explicitly or implicitly setting CURRENT-WINDOW to the handle of a non-default window, the ABL virtual machine (AVM) displays the frame in the default window.

- If the CURRENT-WINDOW does not have a message area and you execute the MESSAGE statement without an explicit or implicit VIEW-AS ALERT-BOX option, the AVM displays the default window in order to display the message in its own message area.

- In a character interface, or at the start of a GUI client session, the ACTIVE-WINDOW, CURRENT-WINDOW, and DEFAULT-WINDOW handles all return the handle of the static window for the current ABL session.

- You can make the default window the current window by assigning DEFAULT-WINDOW to CURRENT-WINDOW.

- You can enable or disable the default window by changing the value of DEFAULT-WINDOW:SENSITIVE (the SENSITIVE attribute).

- You can set the menu bar for the default window by assigning the handle of a menu bar to DEFAULT-WINDOW:MENUBAR (the MENUBAR attribute).

- You can make the default window visible or invisible by changing the value of DEFAULT-WINDOW:VISIBLE (the VISIBLE attribute).

- Because DEFAULT-WINDOW is the initial default parent for ABL frames, you cannot set DEFAULT-WINDOW to the handle of a .NET form’s shadow window. If allowed, this would make the associated .NET form a possible parent for ABL frames, and ABL cannot parent ABL frames to .NET forms. A .NET form’s shadow window handle is provided by the ProWinHandle property of the Progress.Windows.Form class, which an OpenEdge .NET class designed for instantiating .NET forms in an ABL session. Therefore, any attempt to set DEFAULT-WINDOW to a ProWinHandle property value raises a run-time error.

See also

ACTIVE-WINDOW system handle, CURRENT-WINDOW system handle
DSLOG-MANAGER system handle

A handle to logging settings for the DataServers in the current session. The DataServers use a separate log file which you can specify with the DataServer Logging (-dslog) startup parameter. The default filename is dataserv.lg.

**Note:** This system handle only applies to the DataServer for Microsoft SQL Server at present.

**Syntax**

```
DSLOG-MANAGER [:attribute | :method ]
```

**attribute**

An attribute of the DSLOG-MANAGER system handle.

**method**

A method of the DSLOG-MANAGER system handle.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Attribute Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENTRY-TYPES-LIST</td>
<td>LOG-ENTRY-TYPES attribute</td>
</tr>
<tr>
<td>HANDLE attribute</td>
<td>LOG-THRESHOLD attribute</td>
</tr>
<tr>
<td>LOGFILE-NAME attribute</td>
<td>LOGGING-LEVEL attribute</td>
</tr>
<tr>
<td>LOG-THRESHOLD attribute</td>
<td>NUM-LOG-FILES attribute</td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Method Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEAR-LOG()</td>
<td>WRITE-MESSAGE()</td>
</tr>
</tbody>
</table>

For more information about DataServer logging, see *OpenEdge Development: Debugging and Troubleshooting* and *OpenEdge Data Management: DataServer for Microsoft SQL Server*.

ERROR-STATUS system handle

A handle to error information on the last statement executed with the NO-ERROR option.

**Syntax**

```
ERROR-STATUS [:attribute | :method ]
```

**attribute**

Specifies an attribute of the ERROR-STATUS handle.
method

Specifies a method of the ERROR-STATUS handle.

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR attribute</td>
<td></td>
</tr>
<tr>
<td>ERROR-OBJECT-DETAIL attribute</td>
<td></td>
</tr>
<tr>
<td>HANDLE attribute</td>
<td></td>
</tr>
<tr>
<td>INSTANTIATING-PROCEDURE attribute</td>
<td></td>
</tr>
<tr>
<td>NUM-MESSAGES attribute</td>
<td></td>
</tr>
<tr>
<td>TYPE attribute</td>
<td></td>
</tr>
</tbody>
</table>

Methods

- **GET-MESSAGE( ) method (Handle)**
- **GET-NUMBER( ) method**

Examples

The following example uses the NO-ERROR and the ERROR-STATUS handle extensively to demonstrate when ERROR-STATUS attributes are reset:

```
r-errst1.p
CONNECT "db-xyz" NO-ERROR.
RUN chk-connect NO-ERROR.
IF ERROR-STATUS:ERROR THEN
  MESSAGE "Run statement failed.".
PROCEDURE chk-connect:
  DEFINE VARIABLE connect-ok AS LOGICAL NO-UNDO INITIAL TRUE.
  IF ERROR-STATUS:ERROR THEN DO:
    MESSAGE "Connect failed.".
    connect-ok = FALSE NO-ERROR.
    IF ERROR-STATUS:ERROR THEN
      MESSAGE "Assignment failed.".
    END.
  END.
  IF connect-ok THEN RETURN "OK".
  ELSE RETURN "FAILED".
END PROCEDURE.
```

Within the internal procedure, chk-connect, the first reference to ERROR-STATUS:ERROR returns status on the CONNECT statement from the main procedure. The second reference returns status on the assignment statement. The reference to ERROR-STATUS:ERROR in the main procedure returns status on the RUN statement. Note that the ERROR-STATUS attributes are set only after the statement with NO-ERROR completes. Therefore the references in the internal procedure are not affected by the RUN statement itself.

The following procedure accepts a character string value and lets you convert it to one of several data types. The internal convert procedure attempts the conversion. If the conversion is successful, it displays the converted value. If the conversion is unsuccessful, the ERROR-STATUS handle holds error information. After running convert, the CHOOSE trigger checks ERROR-STATUS:ERROR and ERROR-STATUS:NUM-MESSAGES to determine if either error information is available or messages have been returned, even if ERROR is not raised. If either condition is true, this lets you view this information. ABL includes many errors that generate messages, but do not raise the ERROR condition, such as most errors generated by ABL built-in functions and handle methods.
DEFINE VARIABLE txt AS CHARACTER NO-UNDO FORMAT "X(20)".
DEFINE VARIABLE ix AS INTEGER NO-UNDO.

DEFINE BUTTON b_int LABEL "Integer".
DEFINE BUTTON b_date LABEL "Date".
DEFINE BUTTON b_dec LABEL "Decimal".
DEFINE BUTTON b_log LABEL "Logical".
DEFINE BUTTON b_quit LABEL "Quit" AUTO-ENDKEY.

DEFINE FRAME butt-frame
  b_int b_date b_dec b_log b_quit
  WITH CENTERED ROW SCREEN-LINES - 2.
DEFINE FRAME get-info
  txt LABEL "Enter Data To Convert"
  WITH ROW 2 CENTERED SIDE-LABELS TITLE "Data Conversion - Error Check".

ON CHOOSE OF b_int, b_date, b_dec, b_log IN FRAME butt-frame DO:
  IF txt:MODIFIED IN FRAME get-info THEN DO:
    ASSIGN txt.
    RUN convert(txt).
    IF ERROR-STATUS:ERROR OR ERROR-STATUS:NUM-MESSAGES > 0 THEN DO:
      MESSAGE ERROR-STATUS:NUM-MESSAGES " errors occurred during conversion." SKIP
      "Do you want to view them?" VIEW-AS ALERT-BOX QUESTION BUTTONS YES-NO
      UPDATE view-errs AS LOGICAL.
      IF view-errs THEN
        DO ix = 1 TO ERROR-STATUS:NUM-MESSAGES:
        END.
    END.
  ELSE
    MESSAGE "Please enter data to be converted, then choose the type of conversion to perform."
    VIEW-AS ALERT-BOX MESSAGE BUTTONS OK.
  END.

ENABLE ALL WITH FRAME butt-frame.
ENABLE txt WITH FRAME get-info.
WAIT-FOR CHOOSE OF b_quit IN FRAME butt-frame FOCUS txt IN FRAME get-info.
The ERROR attribute indicates whether the ERROR condition was raised during the execution of the last statement that contained the NO-ERROR option. Some errors may occur without raising the ERROR condition. For example, compiler errors do not raise the ERROR condition.

The NUM-MESSAGES attribute indicates the total number of errors that occurred during that statement.

The ERROR-OBJECT-DETAIL attribute identifies a SOAP-fault object that contains SOAP fault message detail.

If a Web service operation generates a SOAP fault message, the AVM generates the following error:

```
Web service %<operation> failed. SOAP faultstring is %s (nnnn)
```

The complete SOAP fault error message is returned to the AVM as part of the ERROR-STATUS system handle.

If the ABL application invokes the Web service operation with the NO-ERROR option on the RUN statement, any errors that occur as a result of the operation are suppressed. In this case, the application can access the SOAP fault message detail using the SOAP-fault and SOAP-fault-detail object handles. Otherwise, the AVM displays the error message to the end user.
The TYPE attribute returns the widget type, PSEUDO-WIDGET.

The GET-MESSAGE method and the GET-NUMBER method let you access the error numbers and messages for all errors that occurred during the execution of the last statement with the NO-ERROR option.

Usually, the NO-ERROR option on a statement suppresses the display of error messages. However, if a STOP condition occurs, the error message is written to the windows. These messages are also available through the ERROR-STATUS attributes. For example, the STOP condition is raised when a procedure to be run is not found. Two specific instances of this are:

- If you use NO-ERROR on a RUN statement and the procedure is not found or cannot compile.
- If you execute a data handling statement, such as DELETE with the NO-ERROR option and the corresponding trigger procedure is not found or cannot compile.

See also SOAP-fault object handle, SOAP-fault-detail object handle

### FILE-INFO system handle

A handle to an operating system file.

#### Syntax

```
FILE-INFO [ :attribute ]
```

**attribute**

Specifies an attribute of the FILE-INFO handle.

#### Attributes

| FILE-CREATE-DATE attribute | FILE-CREATE-TIME attribute | FILE-MOD-DATE attribute |
| ___________________________ | ___________________________ | ________________________ |
| FILE-MOD-TIME attribute    | FILE-NAME attribute        | FILE-SIZE attribute     |
| FILE-TYPE attribute        | FULL-PATHNAME attribute    | HANDLE attribute        |
| INSTANTIATING-PROCEDURE attribute | PATHNAME attribute | TYPE attribute |

#### Example

After you set the value of the FILE-NAME attribute, you can read the values of the other attributes. For example:
r-osfile.p

```plaintext
DEFINE VARIABLE os-file AS CHARACTER NO-UNDO FORMAT "x(60)" LABEL "File".

REPEAT:
  SET os-file WITH FRAME osfile-info.
  DISPLAY FILE-INFO:FULL-PATHNAME FORMAT "x(60)" LABEL "Full Path"
  FILE-INFO:PATHNAME FORMAT "x(60)" LABEL "Path"
  FILE-INFO:FILE-TYPE LABEL "Type"
  WITH FRAME osfile-info SIDE-LABELS TITLE "OS File Info".
END.
```

Notes

- You cannot use the FILE-INFO handle to bypass operating system security. You must have read access to the file and the directory that contains it to obtain information through FILE-INFO.

- These attributes return the Unknown value (?) until they are set, and also if the specified file cannot be found or you do not have permission to access the file.

- If you set the FILE-NAME attribute to a relative pathname, the FILE-INFO handle searches the current PROPATH to locate the file.

- The FILE-TYPE attribute returns a string containing exactly one of the following file type characters:
  - D — If the file is a directory
  - F — If the file is a standard file or FIFO pipe (UNIX systems)
  - M — If the file is a member of an ABL procedure library
  - S — If the file is a special device (UNIX systems)
  - X — If the file type is unknown (contact your Progress Software Corporation Technical Support representative when you receive this value)

The attribute string can contain any of the following file type characters:

- H — If the file is hidden
- L — If the file is a symbolic link (UNIX systems)
- P — If the file is a pipe file (UNIX systems)
- R — If the file is readable
- W — If the file is writable

- The FULL-PATHNAME attribute returns the absolute pathname of the file specified in the FILE-NAME attribute.

- If the FILE-NAME attribute contains a simple filename or relative pathname, the PATHNAME attribute contains the pathname of the specified file starting with the directory on the PROPATH where it is found. Otherwise, the PATHNAME attribute contains the absolute pathname specified in the FILE-NAME attribute.

- The TYPE attribute returns the widget type, PSEUDO-WIDGET.
FOCUS system handle

A handle to the field-level widget that is the current field.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```
FOCUS [ :attribute ]
```

**attribute**

An attribute of the widget that has current input focus.

**Attributes**

The specific attributes available depend on the type of the widget. You can determine the widget type by examining the FOCUS:TYPE attribute.

**Example**

The following example uses the FOCUS handle to provide helpful information to the user. The procedure displays an interface that contains several different types of widgets. If you type ?, the procedure displays a message specifying the type of widget that has focus and whether VALUE-CHANGED event is a valid event for that widget.

**r-focus.p**

```openedge
DEFINE VARIABLE inv-price  LIKE item.price NO-UNDO.
DEFINE VARIABLE inv-value LIKE item.price NO-UNDO.
DEFINE VARIABLE report-type AS INTEGER NO-UNDO INITIAL 1.

DEFINE BUTTON ok-butt  LABEL "OK" AUTO-GO.
DEFINE BUTTON cancel-butt LABEL "CANCEL" AUTO-ENDKEY.

FORM
  inv-price LABEL "Price" AT ROW 1.25 COLUMN 2
  report-type LABEL "Report Sorted ..." AT ROW 2.25 COLUMN 2
  VIEW-AS RADIO-SET
    RADIO-BUTTONS "By Catalog Page", 1, "By Inventory Value", 2 SKIP
  ok-butt cancel-butt
  WITH FRAME select-frame SIDE-LABELS.

ON ? ANYWHERE DO:
  MESSAGE "This is a" FOCUS:TYPE + ". VALUE-CHANGED is"
  (IF VALID-EVENT(FOCUS, "VALUE-CHANGED") THEN "a" ELSE "NOT a")
  "valid event for this widget."
  VIEW-AS ALERT-BOX INFORMATION BUTTONS OK.
  RETURN NO-APPLY.
END.

ENABLE ALL WITH FRAME select-frame.
WAIT-FOR WINDOW-CLOSE OF CURRENT-WINDOW.
```

Note that this example prevents you from entering the question mark character (?) in any field. This does not cause a problem in r-focus.p because a question mark is not a valid input character for any field in the interface.

**Notes**

- A typical use of the FOCUS handle identifies the widget that contains the current text selection for reference by the system clipboard. For an example of this usage, see *OpenEdge Development: Programming Interfaces*. 

1228
Within a WAIT-FOR statement, you can specify the field that receives initial input focus.

You must give input focus to any fill-in widget where you want to set the AUTO-ZAP attribute. For more information, see the SAX-reader object handle reference entry.

See also SELF system handle, WAIT-FOR statement (ABL only)

---

**FONT-TABLE system handle**

*(Windows only; Graphical interfaces only)*

A handle to the current font table.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```
FONT-TABLE [ :attribute | :method ]
```

**attribute**

Specifies an attribute of the FONT-TABLE handle.

**method**

Specifies a method of the FONT-TABLE handle.

**Attributes**

<table>
<thead>
<tr>
<th>HANDLE attribute</th>
<th>INSTANTIATING-PROCEDURE attribute</th>
<th>NUM-ENTRIES attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE attribute</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Methods**

<table>
<thead>
<tr>
<th>GET-TEXT-HEIGHT-CHARS( ) method</th>
<th>GET-TEXT-HEIGHT-PIXELS( ) method</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET-TEXT-WIDTH-CHARS( ) method</td>
<td>GET-TEXT-WIDTH-PIXELS( ) method</td>
</tr>
</tbody>
</table>

**Example**

This code shows how to query and set the integer attribute, NUM-ENTRIES:

```
DEFINE VARIABLE ix AS INTEGER NO-UNDO.
ix = FONT-TABLE:NUM-ENTRIES. /* to query */
/* or */
ix = 255.
FONT-TABLE:NUM-ENTRIES = ix. /* to set */
```

**Notes**

- Unlike the COLOR-TABLE system handle, the FONT-TABLE system handle does not allow you to set fonts dynamically. Font entries can only be changed by the user through the font system dialog box. Fonts are always dynamic.
LAST-EVENT system handle

The current font table is the font table in the current environment, which is the startup environment or the environment most recently specified in a USE statement.

To determine the number of font entries in the font table, query the NUM-ENTRIES attribute.

To change the number of font entries in the font table, set the NUM-ENTRIES attribute.

To allow users to set dynamic font table entries at run time, an application can display a font common dialog with the SYSTEM-DIALOG FONT statement.

To save font definitions from the font table to the current environment file, use the PUT-KEY-VALUE statement. To retrieve the font definition specified in the current environment file, use the GET-KEY-VALUE statement.

The TYPE attribute returns the widget type, PSEUDO-WIDGET.

See also  GET-KEY-VALUE statement, PUT-KEY-VALUE statement, SYSTEM-DIALOG FONT statement, USE statement

LAST-EVENT system handle

A handle to the last event the application received.

Syntax

\[
\text{LAST-EVENT} [ :\text{attribute} ]
\]

\text{attribute}

An attribute of the LAST-EVENT.

Attributes

| CODE attribute | COLUMN attribute | EVENT-TYPE attribute |
| FUNCTION attribute | HANDLE attribute | INSTANTIATING-PROCEDURE attribute |
| LABEL attribute | ON-FRAME-BORDER attribute | ROW attribute |
| TYPE attribute | WIDGET-ENTER attribute | WIDGET-LEAVE attribute |
| X attribute | Y attribute | – |

Example

This procedure creates a variety of widgets and a frame that acts as a message area. As you move around the widgets the procedure tells you what events ABL generates.
For keyboard events, the CODE, FUNCTION, and LABEL attributes return the key code, key function, and key label of the event, respectively. For all other events the CODE attribute returns the numeric event code.

For mouse events, the FUNCTION attribute returns the names of portable mouse events and the LABEL attribute returns the names of three-button mouse events.

For high-level ABL events, the FUNCTION attribute returns the name of the event. If the ABL event is triggered by a key press, the LABEL attribute returns the key label. Otherwise, it returns the event name, as with the FUNCTION attribute.

The EVENT-TYPE attribute returns the category of the event: KEYPRESS, MOUSE, or ABL.

The ON-FRAME-BORDER attribute indicates whether a MOUSE event occurred in the border of a frame.

The TYPE attribute returns the widget type, PSEUDO-WIDGET.

The X and Y attributes return the pixel position of a MOUSE event relative to the current frame.

For browse widgets, WIDGET-ENTER and WIDGET-LEAVE are different depending on whether the browse is editable or read-only. For editable browse widgets,
LOG-MANAGER system handle

WIDGET-ENTER contains the handle of the column with focus. For read-only browse widgets, WIDGET-ENTER contains the handle of the browse. For editable browse widgets, WIDGET-LEAVE contains the handle of the column the user just left. For read-only browse widgets, WIDGET-LEAVE contains the handle of the field-level widget the user just left.

See also
LIST EVENTS function, LIST WIDGETS function, SELF system handle, VALID EVENT function

LOG-MANAGER system handle

A handle to logging settings for the current ABL session.

Syntax

| LOG-MANAGER [ :attribute | :method ] |

attribute

An attribute of the LOG-MANAGER system handle.

method

A method of the LOG-MANAGER system handle.

Attributes

| ENTRY-TYPES-LIST attribute | HANDLE attribute | INSTANTIATING-PROCEDURE attribute |
| LOG-ENTRY-TYPES attribute | LOGFILE-NAME attribute | LOGGING-LEVEL attribute |
| LOG-THRESHOLD attribute | NUM-LOG-FILES attribute | TYPE attribute |

Methods

| CLEAR-LOG( ) method | CLOSE-LOG( ) method |
| WRITE-MESSAGE( ) method | |

For more information about logging, see OpenEdge Development: Debugging and Troubleshooting.

Procedure object handle

A handle that can reference the context of one of the following procedure object instances:

- A persistent procedure in the current session
- A persistent procedure in a remote session (on an AppServer)
• A running procedure in the current session, including the currently executing procedure or any other procedure currently on the session call stack

• A procedure object that encapsulates a Web service operation (Web service procedure object)

This object allows you to read and modify the context of the specified procedure according to the type of procedure object instance.

Syntax

```
procedure-handle [ :attribute | :method ]
```

**procedure-handle**

A handle variable that references a procedure object.

For Web services, this object is instantiated when you execute the RUN ON statement that references a Web service server object.

**attribute**

An attribute of a procedure handle.

**method**

Specifies a method of a procedure handle.

Attributes

<table>
<thead>
<tr>
<th>ADM-DATA attribute</th>
<th>ASYNC-REQUEST-COUNT attribute</th>
<th>CURRENT-WINDOW attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB-REFERENCES attribute</td>
<td>FILE-NAME attribute</td>
<td>HANDLE attribute</td>
</tr>
<tr>
<td>INSTANTIATING-PROCEDURE attribute</td>
<td>INTERNAL-ENTRIES attribute</td>
<td>NAME attribute</td>
</tr>
<tr>
<td>NEXT-SIBLING attribute</td>
<td>PERSISTENT attribute</td>
<td>PREV-SIBLING attribute</td>
</tr>
<tr>
<td>PRIVATE-DATA attribute</td>
<td>PROXY attribute</td>
<td>PUBLISHED-EVENTS attribute</td>
</tr>
<tr>
<td>REMOTE attribute</td>
<td>SERVER attribute</td>
<td>SUPER-PROCEDURES attribute</td>
</tr>
<tr>
<td>TRANSACTION attribute</td>
<td>TYPE attribute</td>
<td>UNIQUE-ID attribute</td>
</tr>
</tbody>
</table>

Methods

<table>
<thead>
<tr>
<th>ADD-SUPER-PROCEDURE() method</th>
<th>GET-SIGNATURE() method</th>
</tr>
</thead>
<tbody>
<tr>
<td>REMOVE-SUPER-PROCEDURE() method</td>
<td>SET-CALLBACK-PROCEDURE() method</td>
</tr>
</tbody>
</table>

Example

The following procedure runs another procedure (`r-thi spr.p`) persistently, setting a procedure object handle for it, and displays the value of its PRIVATE-DATA attribute as a message:
ProDataSet object handle

**r-run-thispr-pers.p**

```plaintext
DEFINE VARIABLE hthispr AS HANDLE NO-UNDO.
RUN r-thispr.p PERSISTENT SET hthispr.
MESSAGE "Running the " hthispr:PRIVATE-DATA VIEW-AS ALERT-BOX INFORMATION.
```

For more information on the `r-thispr.p` example procedure, see the reference entry for the `THIS-PROCEDURE` system handle in this section.

**Notes**
- You can also define triggers for procedure object handles.
- To create an instance of a persistent procedure, use the `PERSISTENT` option of the `RUN` statement, as shown for the `r-run-thispr-pers.p` example procedure. For other examples of creating persistent procedures, see the reference entry for the `RUN` statement.
- You can access the handles and attributes of all persistent procedure instances in a session using the `FIRST-PROCEDURE` or `LAST-PROCEDURE` attribute of the `SESSION` handle.

**See also**  
`RUN` statement, `SESSION` system handle, `THIS-PROCEDURE` system handle

**ProDataSet object handle**

A handle to a ProDataSet object. A ProDataSet object is a collection of one or more related temp-tables. Each temp-table in a ProDataSet object can attach to a data-source object that allows filling of the temp-table from the data source, or updating the data source from the temp-table. A ProDataSet object can optionally contain a set of data relations between the temp-tables.

A ProDataSet object can be static or dynamic. A static ProDataSet object is one you define at compile time with the `DEFINE DATASET` statement. A dynamic ProDataSet object is one you create at run time with the `CREATE DATASET` statement. Use this handle to access the ProDataSet object’s attributes and methods, and its sub-elements (its temp-table buffers, data relations, data sources, and so on) and their attributes and methods.

**Syntax**

```plaintext
dataset-object-handle [ :attribute | :method ]
```

**dataset-object-handle**

An item of type HANDLE representing a handle to a ProDataSet object.

**attribute**

An attribute of the ProDataSet object.

**method**

A method of the ProDataSet object.

Query object handle

Note

For information about dynamically accessing the data in a ProDataSet object, see the reference entries related to the TEMP-TABLE, BUFFER, BUFFER-FIELD, and QUERY objects.

See also

Buffer object handle, CREATE DATASET statement, DEFINE DATASET statement, EMPTY-TEMP-TABLE( ) method, Temp-table object handle

Query object handle

A handle to a query object. A query object corresponds to an underlying ABL query, which can be static or dynamic. An example of a static underlying query is one you define at compile time with the DEFINE QUERY statement. An example of a dynamic underlying query is one you create at run time with the new CREATE QUERY statement.

Syntax

```
query-handle [ :attribute | :method ]
```

- **query-handle**
  - An item of type HANDLE representing a handle to a query object.
- **attribute**
  - An attribute of the query object.
- **method**
  - A method of the query object.

Attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>

| SET-BUFFERS( ) method | SET-CALLBACK( ) method |
| SET-CALLBACK-PROCEDURE( ) method | – |

See also Buffer object handle, Buffer-field object handle

RCODE-INFO system handle

A handle to a specific ABL r-code file.

```
RCODE-INFO [ :attribute ]
```

**attribute**

Specifies an attribute of the RCODE-INFO handle.

Attributes

| CODEPAGE attribute | CRC-VALUE attribute | DB-REFERENCES attribute |
| FILE-NAME attribute | HANDLE attribute | INSTANTIATING-PROCEDURE attribute |
| IS-CLASS attribute | LANGUAGES attribute | MD5-VALUE attribute |
| TABLE-CRC-LIST attribute | TABLE-LIST attribute | TYPE attribute |

Example

The following example prompts for the name of an r-code file and returns its CRC code and the languages for which it is compiled:
Notes

- ABL generates an r-code file when you compile a procedure with the SAVE option of the COMPILE statement. You cannot use the RCODE-INFO handle to get information on session compiles.

- To use the RCODE-INFO handle, you must first set the FILE-NAME attribute to the name of an r-code file (with or without a .r or .p extension). If you do not provide a full pathname, ABL searches your PROPATH to find the file. You can then read the CRC-VALUE attribute and LANGUAGES attribute to get information on the file. If the r-code file is not found, both LANGUAGES and CRC-VALUE are set to the Unknown value (?).

- The LANGUAGES attribute holds a comma-separated list of language names supported by the r-code. The default segment appears in the list as the value <unnamed>.

- The CRC-VALUE attribute returns the r-code CRC value stored in the r-code. The calculation for this value is based on the filename and contents of the procedure file during compilation. This value is different from any database CRCs that are stored in the r-code. For more information on CRCs, see OpenEdge Deployment: Managing ABL Applications.

- The TYPE attribute returns the widget type, PSEUDO-WIDGET.

SAX-attributes object handle

Contains the list of attribute names, values, and optional namespaces of an XML element for use in the SAX-reader or SAX-writer object. The purpose of the object is to hold values needed by the SAX parser to set the attribute values of a new XML element as it reads the element into a SAX-reader object or prepares an XML object for writing in a SAX-writer object.

SAX-attributes objects used by the SAX-reader object are automatically created, populated, and deleted in the context of the startElement callback procedure. In that context, a programmer may use the methods and attributes of the object to modify it. However, if the programmer wants to use the contents of this SAX-attributes object outside of the short scope of the startElement callback, then the programmer must create another SAX-attributes object outside this scope and copy the SAX-reader’s SAX-attributes object to the new object.

---

```
r-rcode.p

DEFINE VARIABLE rcode-file AS CHARACTER NO-UNDO FORMAT "x(60)" LABEL "File".
REPEAT:
  SET rcode-file WITH FRAME rc-info.
  DISPLAY RCODE-INFO:CRC-VALUE LABEL "CRC"
      RCODE-INFO:LANGUAGES FORMAT "x(60)" LABEL "Languages"
        WITH FRAME rc-info SIDE-LABELS TITLE "R-code Check".
END.
```
A SAX-attributes object is an optional parameter for SAX-writer methods that create new XML elements. In this context, a programmer creates a new SAX-attributes object with the CREATE SAX-ATTRIBUTES statement. Typically, a programmer populates the object by using the COPY-SAX-ATTRIBUTES method to save the contents of an automatically created SAX-attributes object. A programmer can also use the other attributes and methods to build up the attributes list from scratch. Either way, once the SAX-attributes object is populated, it can be used as an optional parameter on the START-ELEMENT() method, WRITE-DATA-ELEMENT() method, or the WRITE-EMPTY-ELEMENT() method of the SAX-writer object.

You must explicitly deleted all SAX-attributes objects created with the CREATE SAX-ATTRIBUTES statement.

### Syntax

```plaintext
SAX-attributes-handle [ :attribute | :method ]
```

- **SAX-attributes-handle**: A variable of type HANDLE.
- **attribute**: An attribute of the SAX-attributes object.
- **method**: A method of the SAX-attributes object.

CREATE SAX-READER statement, CREATE SAX-WRITER statement, SAX-reader object handle, SAX-writer object handle
SAX-reader object handle

Provides access to the SAX parser to stream an XML document into the object. The SAX-reader
object, used with the SAX interface, corresponds to the X-document object of the Document
Object Model (DOM) interface, but presents a very different programming interface.

Syntax

```
sax-reader-handle [:attribute | :method]
```

`sax-reader-handle`

A variable of type HANDLE.

`attribute`

An attribute of the SAX-reader object.

`method`

A method of the SAX-reader object.

Client-principal object handle, DECRYPT function, ENCRYPT function, GENERATE-PBE-KEY function, GENERATE-PBE-SALT function, GENERATE-RANDOM-KEY function, MD5-DIGEST function, SHA1-DIGEST function

**SELF system handle**

A handle to the object or widget associated with the currently executing user-interface trigger or event procedure.

**Syntax**

```
SELF [ :attribute ]
```

**attribute**

An attribute of the object or widget associated with the trigger or event procedure.

**Attributes**

The specific attributes available depend on the type of the object or widget. You can determine the object or widget type by examining the SELF:TYPE attribute.

**Example**

The following example uses the SELF handle to display the starting and ending positions of an object you move:
SELF system handle

Notes

- You can reference the SELF handle only within a user-interface trigger or the event procedure for an ActiveX control or asynchronous remote request.

- In user-interface triggers, SELF is not automatically the widget that has input focus. To give input focus to the widget referenced by SELF, you must apply the ENTRY event to SELF within the trigger block. Note that you must do this for fill-in widgets whose AUTO-ZAP attribute you want to set, as in this fragment:

```plaintext
DEFINE VARIABLE fname AS CHARACTER NO-UNDO FORMAT "x(30)" LABEL "Name".
DEFINE FRAME FillFrame fname WITH SIDE-LABELS.
ON ENTRY OF fname IN FRAME FillFrame DO:
    APPLY "ENTRY" TO SELF.
    SELF:AUTO-ZAP = TRUE.
END.
```

This makes SELF = FOCUS, which allows the new AUTO-ZAP value to take effect. For more information on the AUTO-ZAP attribute, see the “Handle Attributes and Methods Reference” section on page 1271.
- In the event procedure of an asynchronous remote request or in the context of a procedure called directly or indirectly by this event procedure, SELF returns the associated asynchronous request handle.

- In the event procedure of an ActiveX control, SELF returns the control-frame handle and the COM-SELF system handle returns the control-frame COM-HANDLE value.

- If referenced within a READ-RESPONSE event procedure, then SELF is the socket handle associated with the connection that received the message. If referenced within the CONNECT event procedure, then SELF is the server socket handle.

**See also**  
Asynchronous request object handle, COM-SELF system handle, FOCUS system handle, LAST-EVENT system handle

---

### Server object handle

 Allows you to connect and execute remote procedures on an AppServer or Web service.

**Note:**  
This handle does not provide direct access to an AppServer session context as does a SESSION handle for the current context. Rather, it provides access to a server object in the current context that allows you to connect, disconnect, and retrieve a variety of information on a connected AppServer.

**Syntax**

```
server-handle [ :attribute | :method ]
```

**server-handle**

A handle variable that references a server object created by the CREATE SERVER statement that, in turn, allows you to connect to and access an AppServer instance or a Web service application.

**attribute**

An attribute of the server handle.

**method**

A method of the server handle.

**Attributes**

<table>

(1 of 2)
Server socket object handle

A handle to a server socket object. This object allows you to listen for and accept TCP/IP socket connections on a given port.

Note: Does not apply to SpeedScript programming.

Syntax

server-socket-handle [:attribute | :method ]

server-socket-handle

A handle variable that references a server socket object created by the CREATE SERVER-SOCKET statement that, in turn, allows you to listen for and accept multiple connections on a given port.

attribute

An attribute of the server socket handle.

method

A method of the server socket handle.

Attributes

<table>

</tr>
</tbody>
</table>

Events

| CONNECT event | -- |

Note

The server socket object is used to enable the AVM to listen to and accept new connections from socket clients; it is via the socket object that clients and servers communicate. For more information on using sockets, see *OpenEdge Development: Programming Interfaces*.

SESSION system handle

A handle to the current ABL session object. This object allows you to read and modify the current ABL session context.

Syntax

```
SESSION [ :attribute | :method ]
```

*attribute*

Specifies an attribute of the SESSION system handle.

*method*

Specifies a method of the SESSION system handle.

Attributes

</tbody>
</table>
Example

The following example uses the SESSION:IMMEDIATE-DISPLAY attribute. When dumping or loading records from the database, the procedure displays a running count of records. If IMMEDIATE-DISPLAY is false, no value is shown until all records are dumped or loaded. At that point, the total is shown. To prevent this, IMMEDIATE-DISPLAY is set to true just before the dump or load and then reset to false afterwards.

r-dstrig.p

```plaintext
DEFINE VARIABLE i AS INTEGER NO-UNDO.

DEFINE SUB-MENU file
    MENU-ITEM viewit LABEL "&View Data"
    MENU-ITEM dumpit LABEL "&Dump Data"
    MENU-ITEM loadit LABEL "&Load Data"
    MENU-ITEM exit LABEL "E&xit".
DEFINE MENU mbar MENUBAR
    SUB-MENU file LABEL "&File".

DEFINE BUTTON b_more LABEL "Next".
DEFINE BUTTON b_exit LABEL "Cancel".

DEFINE FRAME cust-frame
    Customer.CustNum SKIP
    Customer.Name SKIP
    Customer.Phone SKIP
    b_more b_exit
    WITH CENTERED SIDE-LABELS ROW 3.

DEFINE STREAM cust.

PAUSE 0 BEFORE-HIDE.

ON CHOOSE OF b_exit IN FRAME cust-frame DO:
    HIDE FRAME cust-frame NO-PAUSE.
    DISABLE ALL WITH FRAME cust-frame.
    LEAVE.
END.

ON CHOOSE OF b_more IN FRAME cust-frame DO:
    FIND NEXT Customer NO-LOCK NO-ERROR.
    IF NOT AVAILABLE Customer THEN
        RETURN.
    DISPLAY Customer.CustNum Customer.Name Customer.Phone
    WITH FRAME cust-frame.
END.
```
Several attributes of the SESSION handle control the execution of ABL code during the current ABL session. This means that the SESSION handle controls the behavior of any code that you are developing and testing, and the OpenEdge ADE toolset. While the tools of the OpenEdge ADE monitor and set the attributes of the SESSION handle to meet their needs, it is possible that the execution of a procedure that sets attributes of the SESSION handle may affect the display and behavior of the OpenEdge ADE toolset.

The FIRST-PROCEDURE and LAST-PROCEDURE attributes are set or reset when you create or delete the first or last persistent procedure in a session. You can use procedure attributes to navigate the procedure entries, reference information, and manage the user interface for each persistent procedure in the procedure chain accessed by FIRST-PROCEDURE and LAST-PROCEDURE.

For more information on the attributes of procedure handles, see the Procedure object handle reference entry. For information on creating a persistent procedure, see the RUN

ON CHOOSE OF MENU-ITEM viewit DO:
   ENABLE ALL WITH FRAME cust-frame.
   FIND FIRST Customer NO-LOCK NO-ERROR.
   DISPLAY Customer.CustNum Customer.Name Customer.Phone
      WITH FRAME cust-frame.
   APPLY "ENTRY" TO b_more.
END.

ON CHOOSE OF MENU-ITEM dumpit DO:
   DISABLE TRIGGERS FOR DUMP OF Customer.
   ix = 1.
   SESSION:IMMEDIATE-DISPLAY = TRUE.
   OUTPUT STREAM cust TO "customer.d".
   FOR EACH Customer NO-LOCK:
      EXPORT STREAM cust Customer.
      DISPLAY ix LABEL "Records Processed"
         WITH FRAME rec-info SIDE-LABELS ROW SCREEN-LINES / 2 CENTERED.
      ix = ix + 1.
   END.
   SESSION:IMMEDIATE-DISPLAY = FALSE.
   OUTPUT STREAM cust CLOSE.
END.

ON CHOOSE OF MENU-ITEM loadit DO:
   DISABLE TRIGGERS FOR LOAD OF Customer.
   INPUT FROM "customer.d".
   SESSION:IMMEDIATE-DISPLAY = TRUE.
   REPEAT:
      CREATE Customer.
      IMPORT Customer.
      DISPLAY ix LABEL "Records Processed"
         WITH FRAME rec-info SIDE-LABELS ROW SCREEN-LINES / 2 CENTERED.
      ix = ix + 1.
   END.
   INPUT CLOSE.
   SESSION:IMMEDIATE-DISPLAY = FALSE.
END.

IF NOT RETRY THEN
   ASSIGN CURRENT-WINDOW:MENUBAR = MENU mbar:HANDLE
      CURRENT-WINDOW:VISIBLE = TRUE.
   WAIT-FOR CHOOSE OF MENU-ITEM exit.

r-dstrig.p
(2 of 2)
 SESSION system handle reference entry. For information on deleting a persistent procedure, see the DELETE PROCEDURE statement reference entry.

- The FIRST-SERVER and LAST-SERVER attributes are set or reset when you create or delete the first or last server handle in a session. You can use server handle attributes and methods to navigate the current chain of server handles, connect to a running AppServer, reference information on a connected AppServer, access remote persistent procedures running on a connected AppServer, and disconnect from a connected AppServer for each server handle in the chain accessed by FIRST-SERVER and LAST-SERVER.

For more information on the attributes and methods of server handles, see the Server object handle reference entry. For information on creating server handles, see the CREATE SERVER statement reference entry.

- Setting the IMMEDIATE-DISPLAY attribute to TRUE can significantly slow performance. However, some code segments may not execute properly with IMMEDIATE-DISPLAY set to FALSE. If a segment of code requires that IMMEDIATE-DISPLAY is TRUE, you should set the attribute to TRUE immediately before the code segment and change it back to FALSE immediately after the segment.

- In Windows, when execution is blocked for input (by a WAIT-FOR statement, for example), the AVM listens for messages from the windowing system. This allows the AVM to multitask properly with other Windows applications. However, if your ABL application performs long processing without blocking for input, then it may not multitask properly because the AVM does not automatically check for messages from the windowing system. To force the AVM to poll for windowing system messages during this time, you can set the MULTITASKING-INTERVAL attribute to a non-zero value. The lower the value, the more often the AVM checks for messages. This may decrease ABL performance. The maximum value is 9999. A value of 0 inhibits polling until ABL blocks for input.

If you set MULTITASKING-INTERVAL to a non-zero value for a code segment, reset it to 0 immediately after that code.

- The AVM sets the TEMP-DIRECTORY attribute to the value you specify for the Temporary Directory (-T) parameter. If you omit the -T parameter, TEMP-DIRECTORY is set to your current working directory.

- The TYPE attribute returns the widget type, PSEUDO-WIDGET.

- Use the SET-WAIT-STATE method to prevent user and system input, and provide visual feedback during a long computation or other background process. The value you pass determines the type of wait message or cursor the windowing system displays for the user. Passing the value "" to SET-WAIT-STATE ends the wait state. Use this method only for long computations or other processes that force the user to wait significantly longer than the usual response time.

If you set a wait state for your application, the AVM automatically ends the wait state if it displays an alert box, a dialog box, or message update.

- For SpeedScript, the invalid attributes are: APPL-ALERT-BOXES, CONTEXT-HELP-FILE, DATA-ENTRY-RETURN, FIRST-CHILD, HEIGHT-PIXELS, LAST-CHILD, PARAMETER, PIXELS-PER-COLUMN, PIXELS-PER-ROW, SUPPRESS-WARNINGS, SYSTEM-ALERT-BOXES,
THREE-D, TOOLTIPS, V6DISPLAY, WIDTH-PIXELS. The GET-PRINTERS() method is invalid for SpeedScript.

- To access the list of all forms created in a session, use the SESSION handle FIRST-FORM and LAST-FORM attributes along with the NextForm and PrevForm properties of the Progress.Windows.IForm interface. In addition, to .NET forms, this list also contains Progress.Windows.FormProxy object references to all ABL windows created in a session, allowing you to manage .NET forms and ABL windows in a common manner. The SESSION handle FIRST-CHILD attribute, NEXT-SIBLING attribute, LAST-CHILD attribute, and PREV-SIBLING attribute only reference the list of ABL windows in a session.

### SOAP-fault object handle

A handle to a SOAP-fault object. A SOAP-fault object contains information specific to a SOAP fault.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

```plaintext
soap-fault-handle [ :attribute ]
```

- `soap-fault-handle`:
  - A handle variable that references a SOAP-fault object.
- `attribute`:
  - An attribute of the SOAP-fault object.

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HANDLE</td>
<td>INSTANTIATING-PROCE</td>
</tr>
<tr>
<td>DURE attribute</td>
<td>SOAP-FAULT-STRING attribute</td>
</tr>
<tr>
<td>SOAP-FAULT-ATTRIBUTE CODE</td>
<td>SOAP-FAULT-DETAIL attribute</td>
</tr>
<tr>
<td>TYPE attribute</td>
<td>–</td>
</tr>
</tbody>
</table>

**Notes**

- When the AVM detects a SOAP fault message, it converts the SOAP fault message to an ABL error message and creates a SOAP-fault object (identified by the ERROR-OBJECT-DETAIL attribute on the ERROR-STATUS system handle). A SOAP-fault object exists only as long as its related ERROR-STATUS entry (that is, until the execution of another statement containing the NO-ERROR option).

- Use the SOAP-FAULT-DETAIL object handle to access the SOAP fault message detail.

See also

ERROR-STATUS system handle, SOAP-fault-detail object handle
SOAP-fault-detail object handle

A handle to a SOAP-fault-detail object.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

\[ \text{soap-fault-detail-handle} \ [ : \text{attribute} \ | \ : \text{method} ] \]

**soap-fault-detail-handle**

A handle variable that references a SOAP-fault-detail object.

**attribute**

An attribute of the SOAP-fault-detail object.

**method**

A method of the SOAP-FAULT-DETAIL object.

**Attributes**

<table>
<thead>
<tr>
<th>HANDLE attribute</th>
<th>INSTANTIATING-PROCE attribute</th>
<th>TYPE attribute</th>
<th>DURE attribute</th>
</tr>
</thead>
</table>

**Methods**

<table>
<thead>
<tr>
<th>GET-NODE( ) method</th>
<th>GET-SERIALIZED( ) method</th>
</tr>
</thead>
</table>

**Note**

You can use the GET-NODE( ) method to get an X-noderef object handle that refers to the XML that underlies a SOAP-fault-detail object. The application can then use this X-noderef object handle to access the underlying XML. The only restriction is that the application cannot use the X-noderef object handle retrieved from the SOAP-fault-detail object to access the X-document associated with the SOAP-fault object. For more information, see *OpenEdge Development: Web Services.*

SOAP-header object handle

A handle to a SOAP-header object. The object maintains a list of entries. Each entry is associated with an existing SOAP-header-entryref object. A SOAP-header object is passed as an input parameter to a response callback procedure and as an output parameter to a request callback procedure.

**Note:** Does not apply to SpeedScript programming.

**Syntax**

\[ \text{soap-header-handle} \ [ : \text{attribute} \ | \ : \text{method} ] \]
**soap-header-handle**

A handle variable that references a SOAP-header object.

**attribute**

An attribute of the SOAP-header object.

**method**

A method of the SOAP-header object.

### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADM-DATA</td>
<td>HANDLE</td>
</tr>
<tr>
<td>NAME</td>
<td>NUM-HEADER-ENTRIES</td>
</tr>
<tr>
<td>TYPE</td>
<td>UNIQUE-ID</td>
</tr>
</tbody>
</table>

### Methods

<table>
<thead>
<tr>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD-HEADER-ENTRY()</td>
</tr>
<tr>
<td>GET-HEADER-ENTRY()</td>
</tr>
</tbody>
</table>

**Note**

The SOAP-header object is either implicitly created by ABL or explicitly created by the application using the CREATE SOAP-HEADER statement. In either case, the application is responsible for deleting this object. Use the DELETE OBJECT statement to delete a SOAP-header object and its underlying XML.

**See also**

CREATE SOAP-HEADER statement, SOAP-header-entryref object handle

---

**SOAP-header-entryref object handle**

A handle to a SOAP-header-entryref object.

**Note:** Does not apply to SpeedScript programming.

### Syntax

```plaintext
soap-header-entryref-handle [ :attribute | :method ]
```

**soap-header-entryref-handle**

A handle variable that references a SOAP-header-entryref object.

**attribute**

An attribute of the SOAP-header-entryref object.

**method**

A method of the SOAP-header-entryref object.
Attributes

| ACTOR attribute | ADM-DATA attribute | HANDLE attribute |
| INSTANTIATING-PROCEDURE attribute | LOCAL-NAMESPACE-URI attribute | MUST-UNDERSTAND attribute |
| NAME attribute | NAMESPACE-URI attribute | PRIVATE-DATA attribute |
| TYPE attribute | UNIQUE-ID attribute | – |

Methods

| DELETE-HEADER-ENTRY( ) method | GET-NODE( ) method |
| GET-serialized( ) method | SET-actor( ) method |
| SET-MUST-UNDERSTAND( ) method | SET-NODE( ) method |
| SET-serialized( ) method | – |

Notes

- The application is responsible for deleting this object. Use the DELETE OBJECT statement to delete a SOAP-header-entryref object without deleting its underlying XML. To delete the XML underlying the SOAP-header-entryref object, without deleting the object, use the DELETE-HEADER-ENTRY( ) method.

- You can use the GET-NODE( ) method to get an X-noderef object handle that refers to the XML that underlies a SOAP-header-entryref object. The application can then use this X-noderef object handle to access the underlying XML. The only restriction is that the application cannot use the X-noderef object handle retrieved from the SOAP-header-entryref object to access the X-document associated with the SOAP-header object. For more information, see OpenEdge Development: Web Services.

See also

CREATE SOAP-HEADER-ENTRYREF statement, SOAP-header object handle

Socket object handle

A handle to a socket object. This object allows you to read or write data on a TCP/IP socket and to perform other TCP/IP socket actions.

Syntax

```
socket-handle [ :attribute | :method ]
```

socket-handle

A handle variable that references a socket object created by the CREATE SOCKET statement and that allows you to connect to, read from and write to a socket.

attribute

An attribute of the socket handle.

method

A method of the socket handle.
SOURCE-PROCEDURE system handle

A handle to the procedure file that contains the original invocation (RUN statement or function invocation) of the current internal procedure or user-defined function.

Syntax

```
SOURCE-PROCEDURE [ :attribute | :method ]
```

**attribute**

An attribute of the SOURCE-PROCEDURE handle.

**method**

A method of the SOURCE-PROCEDURE handle.

**Attributes**

The SOURCE-PROCEDURE handle supports all the attributes of the procedure object handle. For a list of these attributes, see the reference entry for the Procedure object handle in this section.
Methods

The SOURCE-PROCEDURE handle supports all the methods of the procedure object handle. For a list of these methods, see the reference entry for the Procedure object handle in this section.

Examples

The following scenarios illustrate using SOURCE-PROCEDURE without procedure overriding, with procedure overriding, and with super and non-super RUNs:

**Scenario 1: Using SOURCE-PROCEDURE without procedure overriding**

The following scenario uses SOURCE-PROCEDURE without procedure overriding:

1. A and B are handles of procedure files running persistently.
2. proc1 is an internal procedure that resides in B.
3. A says “RUN proc1 IN B,” which runs B’s proc1.

In this scenario:

- The original run statement for proc1 occurs in Step 3.
- Within B’s proc1 (and within any proc1 that runs as a result of its original RUN statement), SOURCE-PROCEDURE is A.

**Scenario 2: Using SOURCE-PROCEDURE with procedure overriding**

The following scenario uses SOURCE-PROCEDURE with procedure overriding:

1. A, B, and C, and X are handles of procedure files running persistently.
2. B is a super procedure of A, and C is a super procedure of B.
3. proc1 is an internal procedure different versions of which reside in A, B, and C.

**Note:** This is an example of procedure overriding.

4. X says “RUN proc1 IN A,” which runs A’s proc1.
5. A’s proc1 says “RUN SUPER,” which runs B’s proc1.
6. B’s proc1 says “RUN SUPER,” which runs C’s proc1.

In this scenario:

- The original run statement for proc1 occurs in Step 4.
- Within any version of proc1 that runs as a result of its original RUN statement, SOURCE-PROCEDURE is X.

**Scenario 3: With SUPER and non-SUPER RUNs**

The following scenario shows how the value of SOURCE-PROCEDURE changes when a non-super RUN occurs:

1. A, B, and C are handles of procedure files running persistently.
2. B is a super procedure of A, and C is a super procedure of B.

3. proc1 is an internal procedure different versions of which reside in A, B, and C.

4. proc2 is an internal procedure different versions of which reside in A, B, and C.

5. A says “RUN proc1,” which runs A’s proc1.

6. A’s proc1 says “RUN SUPER,” which runs B’s proc1.

7. B’s proc1 says “RUN SUPER,” which runs C’s proc1.

   **Note:** At this point, within any proc1 that runs as a result of its original RUN statement, the value of SOURCE-PROCEDURE is A.

8. C’s proc1 says “RUN proc2,” which runs C’s proc2.

   **Note:** This is a non-super RUN.

In this scenario:

- The original RUN statement for proc1 occurs in Step 5.
- Within any proc1 that runs as a result of its original RUN statement, SOURCE-PROCEDURE is A.
- The original RUN statement for proc2 occurs in Step 8.
- Within any proc2 that runs as a result of its original RUN statement, SOURCE-PROCEDURE is C.

For a sample program that uses SOURCE-PROCEDURE, see the reference entry for the **RUN SUPER** statement.

**Notes**

- You can use SOURCE-PROCEDURE in applications that do not use super procedures.
- In the main block of a procedure, the value of SOURCE-PROCEDURE is the handle of the procedure that ran the current ABL source code or r-code file. This allows any ABL program to identify its caller, and to perform a “callback” to its caller.
- If an ABL or other client runs a procedure on an AppServer, then in the procedure running on the AppServer, the value of SOURCE-PROCEDURE is the Unknown value (?).

**See also**

- ADD-SUPER-PROCEDURE( ) method, REMOVE-SUPER-PROCEDURE( ) method, RUN SUPER statement, SUPER function, SUPER-PROCEDURES attribute, TARGET-PROCEDURE system handle

---

**Stream object handle**

The AVM creates a stream object when an application first tries to get the handle to a given stream. The AVM automatically deletes the stream object when the procedure or class that defines the stream terminates.

1257
TARGET-PROCEDURE system handle

Syntax

STREAM stream-name:attribute

stream-name

The valid name of a stream. If the stream name is invalid, ABL raises a compiler error.

attribute

An attribute of the Stream object.

Attributes

<table>
<thead>
<tr>
<th>ADM-DATA attribute</th>
<th>NAME attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>HANDLE attribute</td>
<td>PRIVATE-DATA attribute</td>
</tr>
<tr>
<td>INSTANTIATING-PROCEDURE attribute</td>
<td>TYPE attribute</td>
</tr>
</tbody>
</table>

Example

This example shows how the HANDLE attribute of the stream object is assigned to hStream:

```
DEFINE VARIABLE hStream AS HANDLE NO-UNDO.
DEFINE STREAM myStream.
hsStream = STREAM myStream:HANDLE.
```

See also

DEFINE STREAM statement

TARGET-PROCEDURE system handle

From within an internal procedure: A handle to the procedure file mentioned, explicitly or implicitly, by the original RUN statement that invoked (perhaps through a chain of super procedures) the current internal procedure.

From within a user-defined function: A handle to the procedure file mentioned, explicitly or implicitly, by the original function invocation that invoked (perhaps through a chain of super versions of functions) the current user-defined function.

Syntax

TARGET-PROCEDURE [ :attribute | :method ]

attribute

An attribute of the TARGET-PROCEDURE handle.

method

A method of the TARGET-PROCEDURE handle.

Attributes

The TARGET-PROCEDURE handle supports all the attributes of the procedure object handle. For a list of these attributes, see the reference entry for the Procedure object handle in this section.
**Methods**

The TARGET-PROCEDURE handle supports all the methods of the procedure object handle. For a list of these methods, see the reference entry for the Procedure object handle in this section.

**Examples**

The following scenarios illustrate using TARGET-PROCEDURE without procedure overriding, with procedure overriding, and with super and non-super RUNs:

**Scenario 1: Using TARGET-PROCEDURE without procedure overriding**

The following scenario uses TARGET-PROCEDURE without procedure overriding:

1. A and B are handles of procedure files running persistently.
2. proc1 is an internal procedure that resides in B.
3. A says “RUN proc1 IN B,” which runs B’s proc1.

In this scenario:

- The original RUN statement for proc1 occurs in Step 3.
- Within proc1 (and any proc1 that runs as a result its original RUN statement), the value of TARGET-PROCEDURE is B.

**Scenario 2: Using TARGET-PROCEDURE with procedure overriding**

The following scenario uses TARGET-PROCEDURE with procedure overriding:

1. A, B, and C, and X are handles of procedure files running persistently.
2. B is a super procedure of A, and C is a super procedure of B.
3. proc1 is an internal procedure, different versions of which reside in A, B, and C.

   **Note:** This is an example of procedure overriding.

4. X says “RUN proc1 in A,” which runs A’s proc1.
5. A’s proc1 says “RUN SUPER,” which runs B’s proc1.
6. B’s proc1 says “RUN SUPER,” which runs C’s proc1.

In this scenario:

- The original RUN statement for proc1 occurs in Step 4.
- Within any version of proc1 that runs as a result of the original RUN statement, the value of TARGET-PROCEDURE is A.

**Scenario 3: With procedure overriding and additional complications**

The following scenario uses TARGET-PROCEDURE with procedure overriding:

1. A, B, and C, and X are handles of procedure files running persistently.
2. B is a super procedure of A, and C is a super procedure of B.

3. proc1 is an internal procedure, different versions of which reside in B and C.

   **Note:** proc1 does not reside in A.

4. X says “RUN proc1 in A,” which runs B’s proc1 (since A has no proc1 and B is a super procedure of A).

5. B’s proc1 says “RUN SUPER,” which runs C’s proc1.

   In this scenario:
   - The original RUN statement for proc1 occurs in Step 4.
   - Within any version of proc1 that runs as a result of its original RUN statement, the value of TARGET-PROCEDURE is A.

**Scenario 4: With SUPER and non-SUPER RUNs**

The following scenario shows how the value of TARGET-PROCEDURE changes when a non-super RUN occurs:

1. A, B, and C are handles of procedure files running persistently.

2. B is a super procedure of A, and C is a super procedure of B.

3. proc1 is an internal procedure different versions of which reside in A, B, and C.

4. proc2 is an internal procedure different versions of which reside in A, B, and C.

5. A says “RUN proc1,” which runs A’s proc1.

6. A’s proc1 says “RUN SUPER,” which runs B’s proc1.

   **Note:** At this point, within any version of proc1 that runs as a result of its original RUN statement, the value of TARGET-PROCEDURE is A.

7. B’s proc1 says “RUN proc2,” which runs B’s proc2.

   **Note:** This is a non-super RUN.

   In this scenario:
   - The original RUN statement for proc2 occurs in Step 7.
   - Within any proc2 that runs as a result of its original RUN statement, the value of TARGET-PROCEDURE is B.

For a sample program that uses TARGET-PROCEDURE, see the reference entry for the RUN SUPER statement.

**Notes**

- You can use TARGET-PROCEDURE in applications that do not use super procedures.
• The value of TARGET-PROCEDURE becomes THIS-PROCEDURE in the following places:
  – Within the main block of a procedure file.
  – Within an internal procedure that is not a super version of another internal procedure.
  – Within a user-defined function that is not a super version of another user-defined function.

ADD-SUPER-PROCEDURE( ) method, REMOVE-SUPER-PROCEDURE( ) method, RUN SUPER statement, SOURCE-PROCEDURE system handle, SUPER function, SUPER-PROCEDURES attribute, TARGET-PROCEDURE system handle

Temp-table object handle

A handle to a temp-table object. A temp-table object handle corresponds to an underlying ABL temp-table, which can be static or dynamic. A static temp-table is one you define at compile time with the DEFINE TEMP-TABLE statement. A dynamic temp-table is one you create at run time with the CREATE TEMP-TABLE statement.

Syntax

```plaintext
temp-table-handle [ :attribute | :method ]
```

*temp-table-handle*

An item of type HANDLE representing a handle to a temp-table object.

*attribute*

An attribute of the temp-table object.

*method*

A method of the temp-table object.

Attributes

<table>
<thead>
<tr>
<th>ADM-DATA attribute</th>
<th>AFTER-TABLE attribute</th>
<th>BEFORE-TABLE attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA-SOURCE-MODIFIED attribute</td>
<td>DEFAULT-BUFFER-HANDLE attribute</td>

<td>NAMESPACE-PREFIX attribute</td>
<td>NAMESPACE-URI attribute</td>
</tr>
<tr>
<td>NO-SCHEMA-MARSHAL attribute</td>
<td>NUM-REFERENCES attribute</td>
<td>ORIGIN-HANDLE attribute</td>
</tr>
<tr>
<td>PREPARED attribute</td>
<td>PRIMARY attribute</td>
<td>PRIVATE-DATA attribute</td>
</tr>
</tbody>
</table>
Methods

<table>
<thead>
<tr>
<th>ADD-FIELDS-FROM() method</th>
<th>ADD-INDEX-FIELD() method</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD-LIKE-FIELD() method</td>
<td>ADD-LIKE-INDEX() method</td>
</tr>
<tr>
<td>ADD-NEW-FIELD() method</td>
<td>ADD-NEW-INDEX() method</td>
</tr>
<tr>
<td>CLEAR() method (Handle)</td>
<td>COPY-TEMP-TABLE() method</td>
</tr>
<tr>
<td>CREATE-LIKE() method</td>
<td>CREATE-LIKE-SEQUENTIAL() method</td>
</tr>
<tr>
<td>READ-JSON() method</td>
<td>READ-XML() method</td>
</tr>
<tr>
<td>READ-XMLSCHEMA() method</td>
<td>TEMP-TABLE-PREPARE() method</td>
</tr>
<tr>
<td>WRITE-JSON() method</td>
<td>WRITE-XML() method</td>
</tr>
<tr>
<td>WRITE-XMLSCHEMA() method</td>
<td>—</td>
</tr>
</tbody>
</table>

Example

The following code fragment demonstrates the creation, definition and use of a temp-table object:

```sql
DEFINE VARIABLE tth AS HANDLE NO-UNDO.
DEFINE VARIABLE bh AS HANDLE NO-UNDO.
DEFINE VARIABLE qh AS HANDLE NO-UNDO.
DEFINE VARIABLE buf-cust-handle AS HANDLE NO-UNDO.

/* Get db table handle as usual */
buf-cust-handle = BUFFER Customer:HANDLE.
/* Create an "empty" undefined temp-table */
CREATE TEMP-TABLE tth.
/* Give it Customer's fields and indexes */
tth:CREATE-LIKE(buf-cust-handle).
/* Give it a single extra field */
tth:ADD-NEW-FIELD("f1","integer").
/* No more fields or indexes will be added to custx */
tth:TEMP-TABLE-PREPARE("custx").
/* Get the buffer handle for the temp-table */
bh = tth:DEFAULT-BUFFER-HANDLE.
/* Populate the table from Customer table */
FOR EACH Customer NO-LOCK:
  bh:BUFFER-CREATE.
  bh:BUFFER-COPY(buf-cust-handle).
END.
/* Run a query to access it*/
CREATE QUERY qh.
qh:SET-BUFFERS(bh).
qh:QUERY-PREPARE("FOR EACH custx WHERE . . .").
...```

Notes

- The temp-table object has three states, CLEAR, UNPREPARED and PREPARED. The
  temp-table is in a CLEAR state either when the temp-table is first created or immediately
after the CLEAR( ) method is applied. The temp-table is in an UNPREPARED state
during the period after the first definitional method has been applied and before the
TEMP-TABLE-PREPARE( ) method is applied. The temp-table is in a PREPARED state
after the TEMP-TABLE-PREPARE( ) method has been applied.

- The user can discern whether the temp-table is in an UNPREPARED or PREPARED state
  by using the PREPARED attribute.

See also  Buffer object handle, CREATE TEMP-TABLE statement, DEFINE TEMP-TABLE statement,
ProDataSet object handle

---

**THIS-PROCEDURE system handle**

A handle to the procedure object for the currently executing procedure. This object allows you
to read and modify the context of the current procedure.

**Syntax**

```
THIS-PROCEDURE [ :attribute | :method ]
```

- **attribute**
  - An attribute of THIS-PROCEDURE.

- **method**
  - Specifies a method of THIS-PROCEDURE.

**Attributes**
The THIS-PROCEDURE handle supports all the attributes of the procedure object handle. For
a list of these attributes, see the reference entry for the Procedure object handle in this section.

**Methods**
The THIS-PROCEDURE handle supports all the methods of the procedure object handle. For
a list of these methods, see the reference entry for the Procedure object handle in this section.

**Examples**
The following procedure is designed to run both persistently and non-persistently. It sets up a
query on the Customer table of the Sports2000 database that is selectable by Name or Balance.
The procedure uses the THIS-PROCEDURE handle to distinguish between persistent and non-persistent instances of execution. When r-thispr.p is persistent (THIS-PROCEDURE:PERSISTENT = TRUE), it:

- Sets the PRIVATE-DATA attribute to help identify it to other procedures.
- Creates a private widget pool to maintain its dynamic window for as long as the procedure instance persists.
- Defines a trigger to delete the procedure when it is terminated. Note that the trigger calls the internal procedure destroy-query, which can be executed by other external procedures to delete r-thispr.p when it is persistent. This destroy-query routine references the
THIS-PROCEDURE handle to delete its persistent parent. It also deletes the widget pool that maintains the dynamic window.

When r-thispr.p is non-persistent (THIS-PROCEDURE:PERSISTENT = FALSE), it invokes a WAIT-FOR statement rather than defining a trigger to terminate the procedure. It does not need to create a widget pool or maintain any other persistent context.

Note that because both persistent and non-persistent instances of this procedure use a dynamic window separate from the default window, r-thispr.p assigns the window’s handle to the procedure’s CURRENT-WINDOW attribute. This makes the dynamic window current whether or not the procedure is persistent. However, when the procedure is persistent, the CURRENT-WINDOW attribute keeps the dynamic window current while other procedures execute using different windows. Because the persistent procedure has its own current window, its triggers and internal procedures do not have to reset the current window every time they execute.

Notes

• By determining if the current procedure is persistent, you can decide whether or not to perform certain actions. An action that you might perform during a non-persistent procedure is to execute a WAIT-FOR statement to provide interactive I/O blocking. Actions that you might execute during a persistent procedure include creating a new window to parent all other widgets created in the procedure, or maintaining an unscoped record buffer that lasts as long as the procedure persists.

• To create an instance of a persistent procedure, use the PERSISTENT option of the RUN statement. For an example, see the reference entry for the Procedure object handle in this section.

• If THIS-PROCEDURE is persistent and the NEXT-SIBLING or PREV-SIBLING attributes are invalid, THIS-PROCEDURE specifies the last or first persistent procedure instance (respectively) in the session persistent procedure chain. To check the validity of these attributes, use the VALID-HANDLE function.

Procedure object handle, RUN statement, SESSION system handle, VALID-HANDLE function

Transaction object handle

Provides access to the current transaction object. This object allows you to query status of and control the current transaction context.

Syntax

```
transaction-handle [ :attribute | :method ]
```

transaction-handle

A handle variable whose value you return from the TRANSACTION attribute on a procedure object handle.

attribute

An attribute of the transaction handle.
### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT-COMMIT attribute</td>
<td>Provides access to information on the current connection to the Web server.</td>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET-COMMIT() method</td>
<td></td>
</tr>
<tr>
<td>SET-ROLLBACK() method</td>
<td></td>
</tr>
</tbody>
</table>

### Notes

- In an AppServer session, if a transaction initiating procedure is active, this handle allows you to control the (automatic) transaction using all of the supported attributes and methods. For more information on automatic transactions, see the TRANSACTION-MODE AUTOMATIC statement reference entry.
- In an ABL client session or in an AppServer session with no active transaction initiating procedure, only the IS-OPEN attribute is available.
- If a transaction initiating procedure is deleted, any open transaction is committed or rolled back according to the value of the DEFAULT-COMMIT attribute.
- The value of this attribute remains the same (references the same transaction context) for the duration of an ABL session. This is true in the following instances:
  - Whether or not a transaction is opened or closed.
  - In an AppServer session, whether or not a transaction initiating procedure is created or deleted.
- For information on transaction objects in an AppServer session, see *OpenEdge Application Server: Developing AppServer Applications*.

### WEB-CONTEXT system handle

Provides access to information on the current connection to the Web server.

**Note:** Applies to SpeedScript programming, not ABL.

### Syntax

```
WEB-CONTEXT [ :attribute | :method ]
```

**attribute**

An attribute of the WEB-CONTEXT handle.
method

A method of the WEB-CONTEXT handle.

X-document object handle

A handle to an X-document object. You create the handle and assign it to a handle variable with the CREATE X-DOCUMENT statement.

Syntax

```
x-document-handle [ :attribute | :method ]
```

`x-document-handle`

A handle variable that references an X-document object.

`attribute`

An attribute of the X-document object.
X-noderef object handle

**method**

A method of the X-document object.

**Attributes**

CREATE X-DOCUMENT statement, X-noderef object handle

**X-noderef object handle**

A handle to a reference to an XML node. The X-noderef object is an ABL object that is a reference to any arbitrary node in an XML tree except a document node. You create the handle and assign it to a handle variable with the CREATE X-NODEREF statement.

An X-noderef object is not in a fully usable state until it has been associated with an X-document. Before this, you can only access its HANDLE, TYPE, PRIVATE-DATE, and UNIQUE-ID attributes without error. To avoid run-time errors, the following code shows one way to test the status of an X-noderef object:

```
cType = X-noderef:SUBTYPE NO-ERROR.
IF VALID-HANDLE(X-noderef) AND cType = 'ELEMENT' THEN DO:
   /** your code ***/
END.
```
X-noderef object handle

Syntax

\[ \text{x-noderef-handle} [ :\text{attribute} | :\text{method} ] \]

\text{x-noderef-handle}

A handle variable that references an X-noderef object. You can use this handle as a parameter or return-value for attributes and methods that provide access to the underlying XML node.

\text{attribute}

An attribute of the X-noderef object.

\text{method}

A method of the X-noderef object.

Attributes

| ATTRIBUTE-NAMES attribute | CHILD-NUM attribute | HANDLE attribute |
| INSTANTIATING-PROCEDURE attribute | LOCAL-NAME attribute | NAME attribute |
| NAMESPACE-PREFIX attribute | NAMESPACE-URI attribute | NODE-VALUE attribute |
| NUM-CHILDREN attribute | OWNER-DOCUMENT attribute | SUBTYPE attribute |
| TYPE attribute | UNIQUE-ID attribute | -- |

Methods

| APPEND-CHILD( ) method | CLONE-NODE( ) method |
| DELETE-NODE( ) method | GET-ATTRIBUTE( ) method |
| GET-ATTRIBUTE-NODE( ) method | GET-CHILD( ) method |
| GET-PARENT( ) method | INSERT-BEFORE( ) method |
| LONGCHAR-TO-NODE-VALUE( ) method | MEMPTR-TO-NODE-VALUE( ) method |
| NODE-VALUE-TO-LONGCHAR( ) method | NODE-VALUE-TO-MEMPTR( ) method |
| NORMALIZE( ) method | REMOVE-ATTRIBUTE( ) method |
| REMOVE-CHILD( ) method | REPLACE-CHILD( ) method |
| SET-ATTRIBUTE( ) method | SET-ATTRIBUTE-NODE( ) method |
Note  The value of the UNIQUE-ID attribute on this handle is guaranteed to be unique only for the life cycle of the single XML document instance to which it belongs (the currently-associated X-document object handle). Once the currently-associated x-document handle is deleted, any new XML document (referenced with a new X-document handle value) can re-use the UNIQUE-ID attribute values for the x-noderef objects of the deleted document. Thus, you can track the uniqueness of x-noderef object instances within an ABL session by remembering each pair of UNIQUE-ID attribute values from a given x-noderef object handle and its associated x-document object handle.

See also CREATE X-NODEREF statement, X-document object handle
Handle Attributes and Methods Reference

This section contains reference entries that describe each handle attribute, handle method, COM object property, and COM object method that ABL supports. Handle attributes and methods, and COM object properties and methods, are all mechanisms that allow you to monitor and control the behavior of ABL handle-based objects (including widgets), system handles, and COM objects.

For information on ABL widgets, see the “Widget Reference” section on page 1143. For information on all other handle-base objects and system handles, see the “Handle Reference” section on page 1189. For information on handle attributes and methods that apply to SpeedScript, see the “Handle Reference” section on page 1189.

Each handle-based object has a set of attributes and methods (referred to generally as handle attributes and handle methods). Each COM object also has a set of properties and methods. This section describes every handle attribute and method available in ABL, but describes only the COM object properties and methods that directly support the ActiveX control container technology in ABL. All other Automation objects and ActiveX controls that you access from ABL provide their own COM object properties and methods. For more information on these properties and methods, see the documentation that comes with each COM object.

In this section, names of handle attributes and methods appear in all-uppercase, while names of COM object properties and methods, which follow Visual Basic coding conventions, appear in mixed case.

This section begins by explaining the syntax for handle-based object references. The basic syntax is similar for both handle-based and COM objects. However, it has been extended for COM objects to support the unique features of Automation objects and ActiveX controls. This extended syntax for COM object references follows in a separate section.
The descriptions that follow refer to both compile-time and run-time behavior, features that the language generally supports and determines at compile time and actions directed by using these features at run time. When describing compile-time features or actions, this section references ABL or the ABL compiler. When describing ABL-directed actions taken at run time, this section references the ABL Virtual Machine (AVM).

Notes: In character interfaces, all handle attributes and methods that reference pixels (for example, the HEIGHT-PIXELS attribute and the GET-TEXT-HEIGHT-PIXELS method) use a system default pixel value for the equivalent value in characters.

Properties and methods of classes are conceptually analogous to but different from either handle attributes and methods or COM object properties and methods. Class-based properties and methods participate in class hierarchies that you typically define, extend, and instantiate as objects of a user-defined class or interface type. All handle attributes and methods are associated with ABL handle-based objects, and are entirely defined and made available by ABL. COM object properties and methods are associated with pre-defined COM objects (Automation objects and ActiveX controls). The syntax for accessing all types of attributes, methods, and properties is very similar, but differ depending on the type of object with which they are associated. This section describes how to access the attributes, properties, and methods of respective ABL handle-based objects and COM objects only. For more information on accessing properties and methods of a class-based object, see the Class-based property access and Class-based method call reference entries.

Accessing handle attributes and methods

A handle attribute is a value that defines a visible, functional, and other characteristic of an ABL handle-based object. System handles also have attributes that describe and control certain handle-based object or system states. Attributes can be readable, writeable, or both. Readable means that your code can assign the value of the attribute to a variable or reference its value in an expression. Writeable means that your code can change the value of an attribute and thereby change the associated characteristic of the object or system state. Whether or not an attribute is readable or writeable depends on a number of factors (for example, the widget type, system handle type, widget realization, etc.).

A handle method is a specialized function associated with an ABL handle-based object that performs an action on the object, or alters the behavior of the object. Some system handles also have methods that affect certain widget and system behaviors. All methods return a value and some methods require parameters. The return value usually is a logical value specifying whether or not the execution of the method was successful. However, some methods return other types of information.

Handle-based references

You must access all handle attributes and methods with reference to a handle-based object or its handle using this general syntax:

Syntax

```
handle-based-reference : attribute-or-method-access
  [ IN container-widget-name ]
```
The `handle-based-reference` must conform to the following syntax:

**Syntax**

```
{ object-name-reference | handle-reference }
```

An `object-name-reference` is a name reference to a static handle-based object, such as the defined name of a frame or window, or of another static handle-based object, such as a temp-table or buffer. For more information, see the “Object name references” section on page 1273. A `handle-reference` can be a handle value that references any handle-based object (static or dynamic), or it can be a system handle. For more information, see the “Handle references” section on page 1274.

The `attribute-or-method-access` identifies a given attribute or method associated with the specified `handle-based-reference`.

The `container-widget-name` is a name reference to a static container widget for the static widget referenced by `object-name-reference`. You need it only if the static widget reference is ambiguous.

For more information on `attribute-or-method-access` and how to access:

- Attributes, see the “Handle attribute access” section on page 1275
- Methods, see the “Handle method calls” section on page 1275

The following sections provide more information on the `object-name-reference` and `handle-reference` options.

**Object name references**

An `object-name-reference` can have the following syntax, depending on the static handle-based object:

**Syntax**

```
[ object-type ] object-name
```

The `object-type` is the type of the static handle-based object specified in the DEFINE statement for the handle-based object, such as FRAME in the DEFINE FRAME statement or TEMP-TABLE in the DEFINE TEMP-TABLE statement. For a data representation widget associated with a field or variable, `object-type` is the widget specified using the VIEW-AS phrase, such as COMBO-BOX for VIEW-AS COMBO-BOX.

The `object-name` is the name that you specify for the static handle-based object using the DEFINE statement for the handle-based object. For a data representation widget, it is the name of the field or variable associated with the widget.

For static frame fields, you only need to provide the `object-name` (field or variable name) to reference the associated widget, and ABL looks for its data representation widget in a frame. However, for most other static handle-based objects, you must qualify the `object-name` with the `object-type`, for example, BUFFER Customer, QUERY qCust, or TEMP-TABLE ttCust.
For example, in this code fragment, the handle to a frame field (dDate) and the handle to a buffer object (bCust) are both returned and assigned to handle variables using the HANDLE attribute of each handle-based object:

```
DEFINE VARIABLE hField AS HANDLE NO-UNDO.
DEFINE VARIABLE hObject AS HANDLE NO-UNDO.
DEFINE VARIABLE dDate AS DATE NO-UNDO VIEW-AS FILL-IN.
DEFINE BUFFER bCust FOR Customer.
DEFINE FRAME AFrame
dDate  
  bCust.Name.

hField  = dDate:HANDLE /* Widget name found in frame AFrame */.
hObject = BUFFER bCust:HANDLE.
```

Handle references

A **handle-reference** allows you to directly reference a handle-based object using a handle value. You can set this handle value by assigning the HANDLE attribute of a static handle-based object (see the “Object name references” section on page 1273), by creating a dynamic handle-based object, by assigning the handle value provided by a system handle, or from any other source of handle values, such as method or function return values. Examples of handle references include CURRENT-WINDOW and BUFFER bCust:HANDLE (from the previous example).

You can access the handle to a static handle-based object using a HANDLE data type (field or variable) that you set to the value of the HANDLE attribute on the static object name reference.

You can access the handle for a dynamic handle-based object through a HANDLE data type (field or variable) whose value is initially set using the CREATE statement for the specified handle-based object. You can also access the handle value to some dynamic handle-based objects, as in the case of a procedure object, that you initially obtain using an appropriate RUN statement or system handle.

The HANDLE attribute of a given object handle can also provide a valid handle value that references the same handle-based object as the given object handle, itself. For example, the following assignment statements set both hProc1 and hProc2 to the same running procedure object using the THIS-PROCEDURE system handle and its HANDLE attribute, and the MESSAGE statement displays the FILE-NAME attribute for the same procedure object:

```
DEFINE VARIABLE hProc1 AS HANDLE NO-UNDO.
DEFINE VARIABLE hProc2 AS HANDLE NO-UNDO.

/* hProc1 equals hProc2 */
hProc1 = THIS-PROCEDURE.
hProc2 = THIS-PROCEDURE:HANDLE.

MESSAGE hProc1:FILE-NAME SKIP hProc2:FILE-NAME VIEW-AS ALERT-BOX.
```
Handle attribute access

To access a handle attribute, use the following syntax:

Syntax

\[
\text{widget-reference} : \text{attribute-name} \ [\text{IN container-widget-name}] 
\]

The \text{widget-reference} is a reference to a handle-based object (see the “Handle-based references” section on page 1272). The \text{attribute-name} specifies the ABL-defined name of a handle-based object attribute. The \text{container-widget-name} is a name reference to a static container for a static widget. You need it only if the static widget reference is ambiguous without it, as shown in the following example. For more information on accessing attributes, see the “Accessing handle attributes and methods” section on page 1272.

To read an attribute value, assign the attribute value to a field or variable of a compatible data type, pass the attribute as an input parameter to some procedure, function, or method, or include the attribute in an expression. To write an attribute value, assign the value to the attribute or pass the attribute as an output parameter to some procedure, function, or method.

The following example repositions a selection list (\text{Select-1}) to another row in the specified frame (\text{SelectFrameA}):

```
DEFINE VARIABLE Select-1 AS CHARACTER NO-UNDO
    VIEW-AS SELECTION-LIST SIZE 50.0 BY 10.0.
DEFINE FRAME SelectFrameA Select-1.
DEFINE FRAME SelectFrameB Select-1.
Select-1:ROW IN FRAME SelectFrameA = Select-1:ROW + 2.
```

Note that ABL assumes that the second reference to \text{Select-1} within the same assignment statement is in the same frame that is specified for the first reference.

Handle method calls

To invoke (execute) a handle method, use the following syntax:

Syntax

\[
\text{widget-reference} : \text{method-name} (\ [\text{parameter-list}] ) \ [\text{IN container-widget-name}] 
\]

The \text{widget-reference} is a reference to a handle-based object (see the “Handle-based references” section on page 1272). The \text{method-name} specifies the ABL-defined name of a handle method, and \text{parameter-list} specifies any parameter list for the method. The \text{container-widget-name} is a name reference to a static container for a static widget. You need it only if the static widget reference is ambiguous, as shown in the following example. To execute a handle method, you can assign the return value directly to a variable, include the method in an expression, or directly invoke the method as a statement (terminated with a period), ignoring its return value. For more information on calling handle methods, see the “Accessing handle attributes and methods” section on page 1272.
The following example executes the ADD-FIRST( ) method for a selection list (Select-1) in two different ways—assigning the return value to a logical variable (methRtn) and invoking it directly, without assigning a value:

```abl
DEFINE VARIABLE Select-1 AS CHARACTER NO-UNDO
   VIEW-AS SELECTION-LIST SIZE 50.0 BY 10.0.
DEFINE VARIABLE methRtn AS LOGICAL NO-UNDO.

DEFINE FRAME SelectFrameA Select-1.
DEFINE FRAME SelectFrameB Select-1.

methRtn = Select-1:ADD-FIRST("BLUE") IN FRAME SelectFrameA.
Select-1:ADD-FIRST("GREEN") IN FRAME SelectFrameB.
```

**Error handling for handle method calls**

Traditionally, ABL handle methods treat errors as warnings and do not raise the ERROR condition. Therefore, statements calling handle methods should use the NO-ERROR option to capture error messages in the ERROR-STATUS system handle. If an error occurs in the handle method and NO-ERROR is in effect, the ERROR-STATUS:ERROR attribute is not set, but you can test to see if ERROR-STATUS:NUM-MESSAGES is greater than zero.

However, if a handle method error occurs in a block that contains a CATCH end block, the AVM does raise the ERROR condition. The error then needs to be handled by a CATCH block, with an appropriate ON ERROR phrase or ROUTINE-LEVEL ON ERROR UNDO, THROW statement to override the default error handling for the block type, if necessary.

When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

If an error object is thrown to a statement that includes the NO-ERROR option, the information and messages in the error object will be used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.
Chained handle references

A chained handle reference has the following syntax:

Syntax

\[
\text{widget-reference} : \text{attribute-or-method-reference} \\
[ : \text{attribute-or-method-reference} ] ... 
\]

A chained handle reference allows you to reference multiple object handles in a series that terminates with a final handle attribute or method. The \text{widget-reference} specifies a handle-based object (see the “Handle-based references” section on page 1272). The \text{attribute-or-method-reference} can be any appropriate attribute or method of the referenced handle-based object immediately preceding it. When you use this syntax, the middle handle attributes and methods must return a data type of HANDLE in order to allow an additional handle reference in the chain, until the final handle attribute or method is accessed, which can return any ABL data type.

The following example shows a chained handle reference (see also \text{Widget phrase, HANDLE function}):

\[
\begin{align*}
&\text{DEFINE VARIABLE hBuff AS HANDLE NO-UNDO.} \\
&\text{CREATE BUFFER hBuff FOR TABLE "Customer".} \\
&\text{MESSAGE hBuff:BUFFER-FIELD(3):NAME.}
\end{align*}
\]

Widget color, font, and measurement values

Some entries in this section refer to color and font values (for example, BGCOLOR and FONT). These values are color and font numbers established for your system. Some entries in this section also refer to character units, an ABL unit of measure for specifying portable widget sizes and positions in graphical environments. For more information on color and font values, or character units and their relationship to pixels, see \text{OpenEdge Development: Programming Interfaces}.

Note: When you assign a decimal value to an attribute representing a measurement in character units, ABL automatically rounds the assigned value to the nearest decimal value that corresponds to whole pixel units.

Accessing COM object properties and methods

A \text{COM object property} is a value that defines the visible, functional, and other characteristics of a COM object (ActiveX Automation object or ActiveX control). An ActiveX control property is classified as a design-time or run-time property depending on when you can change it. A design-time property can be changed using the Properties Window of the AppBuilder. A run-time property can be changed from ABL at run time. Generally, you can read both design-time and run-time properties at run time. In all other respects, COM object properties are functionally analogous to handle attributes.
A **COM object method** is a specialized function associated with a COM object that performs an action on the COM object or alters the behavior of the COM object. COM object methods may or may not return a value and may or may not require parameters. A return value may be a component handle to another COM object; however, many methods return other types of information or no information at all. Like handle methods, you execute COM object methods by calling them directly as statements rather than as part of an expression. In all other respects, COM object methods are functionally analogous to handle methods.

The basic syntax for accessing COM object properties and methods from ABL is similar to accessing handle attributes and methods. These are the main differences:

- You must access a COM object property or method with reference to an instantiated COM object. ABL supports the COM-HANDLE data type to provide COM object references for accessing properties and methods.
- You might have to specify the parameters of COM object methods with more type information, depending on the method and how the COM object is implemented.
- All COM objects are dynamic objects, so you never qualify a COM object reference by a static container reference (such as a static frame or menu widget).

### Syntax for accessing COM object properties and methods

These are the three basic types of ABL statements for accessing properties and methods:

- **Property write**
- **Property read**
- **Method call**

**Note:** You can access COM object properties and methods from many other types of ABL statements that use these properties and methods in a similar fashion. The following statements, however, illustrate all the basic mechanisms for accessing COM objects from ABL.

### Property write

The following syntax describes a basic assignment (=) statement for writing a COM object property:

**Syntax**

```
Com-Handle-Var : COMProperty [ AS Data-type ] = expression
[ NO-ERROR ]
```

*Com-Handle-Var* is any COM-HANDLE variable set to the handle of an instantiated COM object. *COMProperty* is a COM object property access (see the “COMProperty” section on page 1279). *Data-type* is any supported COM data type (see the “Data-type” section on page 1281) that is compatible with *expression*. The *expression* is any combination of ABL elements that results in a single value. NO-ERROR allows the application to handle any ABL ERROR conditions raised by the statement.
Property read

The following syntax describes a basic assignment (=) statement for writing a COM object property:

Syntax

\[
\{ field | COMProperty \} = \]

\[
Com-Handle-Var : COMProperty [ NO-ERROR ]
\]

A field is any ABL variable, database field, class-based data member or property, or handle attribute of a compatible data type. COMProperty is a COM object property access (see the “COMProperty” section on page 1279). Com-Handle-Var is any COM-HANDLE variable set to the handle of an instantiated COM object. NO-ERROR allows the application to handle any ABL ERROR conditions raised by the statement.

Method call

The following syntax describes either a basic assignment (=) statement for invoking a COM object method that returns a value or the basic statement for invoking a COM object method directly that ignores any returned value:

Syntax

\[
\{ field | COMProperty \} = \]

\[
NO-RETURN-VALUE \]

\[
Com-Handle-Var : COMMethod [ NO-ERROR ]
\]

A field is any ABL variable, database field, class-based data member or property, or handle attribute of a compatible data type. COMProperty is a COM object property access (see the “COMProperty” section on page 1279). NO-RETURN-VALUE indicates that you are invoking the COM object method directly, as a statement, without returning its value. Com-Handle-Var is any COM-HANDLE variable set to the handle of an instantiated COM object. COMMethod is a COM object method access (see the “COMMethod” section on page 1280 section). NO-ERROR allows the application to handle any ABL ERROR conditions raised by the statement.

Note: You can invoke both a property read and a method as part of an expression within another statement (such as in a DISPLAY statement or the right side of an assignment (=) statement). You can also directly invoke both property reads and methods as statements in themselves. However, direct invocation is meaningful only for methods.

COMProperty

The following syntax describes a COM object property access with optional chaining of COM object references:

Syntax

\[
\{ COMProperty | COMMethod \} : \]

\[
Property-Name [ ( index [ , index ] ... ) ]
\]

1279
Property-Name is the name of the accessed property. The optional multi-level index is an integer expression as required by the property. You must not follow the colon separator by a space.

Any COMProperty or COMMethod that precedes the final Property-Name must return a COM object reference that provides access to the immediately following Property-Name. The final property access can return any supported COM data type.

COMMethod

The following syntax describes a COM object method access with optional chaining of COM object references:

Syntax

\[
\begin{align*}
&[ \{ \text{COMProperty} | \text{COMMethod} \} : ] \ldots \\
&\text{Method-Name}( \[ \text{COMparm} [ , \text{COMparm} ] \ldots ])
\end{align*}
\]

This syntax describes a potential chain of COM object references that result in a COM object method call. Method-Name is the effective name of the invoked method. COMparm is a parameter as required by the method (see the “COMParm” section on page 1280). You must not follow the colon separator by a space.

Any COMProperty or COMMethod that precedes the final Method-Name must return a COM object reference that provides access to the immediately following Method-Name. The final method call can return any supported COM data type.

COMParm

The following syntax describes how to specify a COMparm for a COM object method:

Syntax

\[
\begin{align*}
&\{ [ \text{OUTPUT} | \text{INPUT-OUTPUT} ] \text{expression} [ \text{AS Data-type} ] \\
&[ \text{BY-POINTER} | \text{BY-VARIANT-POINTER} ] \\
&| \text{null-parm}
\end{align*}
\]

The expression can be any valid ABL expression or data element. Data-type is a supported COM data type that is compatible with the expression. A null-parm is any amount of white space. For information on COM data types and on OUTPUT, INPUT-OUTPUT, BY-POINTER, and BY-VARIANT-POINTER, see the “Data-type” section on page 1281.

Note: There is currently no support for named parameters, for example:

\[\text{Method-Name(Color="GREEN", Shape="SQUARE") Data-type}\]
Data-type

The following syntax lists the supported COM data types for specifying any \textit{Data-type} required for accessing a COM object property or method:

\textbf{Syntax}

\begin{verbatim}
SHORT | FLOAT | CURRENCY | UNSIGNED-BYTE | ERROR-CODE | IUNKNOWN
\end{verbatim}

The requirements for using the \texttt{OUTPUT}, \texttt{INPUT-OUTPUT}, \texttt{BY-VARIANT-POINTER}, \texttt{BY-POINTER}, and \texttt{AS Data-type} options depend on the COM object method or property, the implementation of the COM object, and how you plan to use the parameter or property in your application. In many cases, \textit{expression} is all that you require for a property write or method parameter. For more information on and examples of accessing COM object properties and methods, see the information on COM object references in the chapter on ActiveX Automation and in the chapter on control container support in \textit{OpenEdge Development: Programming Interfaces}.

\section*{ACCELERATOR attribute}

The key label of the keyboard accelerator for the menu item.

\begin{itemize}
  \item \textbf{Data type:} CHARACTER
  \item \textbf{Access:} Readable/Writeable
  \item \textbf{Applies to:} MENU-ITEM widget
\end{itemize}

\section*{ACCEPT-CHANGES( ) method}

Accepts changes to the data in one temp-table or all temp-tables in a ProDataSet object.

\begin{itemize}
  \item \textbf{Return type:} LOGICAL
  \item \textbf{Applies to:} Buffer object handle, ProDataSet object handle
\end{itemize}

\textbf{Syntax}

\begin{verbatim}
handle:ACCEPT-CHANGES( )
\end{verbatim}

\textit{handle}

A handle to the temp-table buffer or the ProDataSet object.

When you accept changes on a ProDataSet object handle, the AVM makes the rows in all after-image tables the current version of those rows, and empties the before-image tables. When you accept changes for a Buffer object handle, the AVM makes the rows in the after-image table the current version of those rows, and empties the before-image table. In either case, the AVM sets the BEFORE-ROWID attribute of every row in the after-image tables to the Unknown value (?), and the ROW-STATE of every row in the after-image tables to ROW-UNMODIFIED (0).
**ACCEPT-ROW-CHANGES( ) method**

Accepts changes to the data in one row of a ProDataSet temp-table.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle

**Syntax**

```
handle:ACCEPT-ROW-CHANGES( )
```

handle

A handle to a before-image temp-table buffer.

When you accept changes for a temp-table row, the AVM makes the row in the after-image table the current version of the row, and then removes the before-image table row. The AVM also sets the BEFORE-ROWID attribute of the row in the after-image table to the Unknown value (?), and the ROW-STATE of the row in the after-image table to ROW-UNMODIFIED (0).

**ACTIVE attribute**

Indicates whether an individual data-relation between two ProDataSet object buffers is active or inactive. Set to TRUE to activate an individual data-relation. Set to FALSE to deactivate a data-relation.

Alternatively, you can activate or deactivate all data-relations in a ProDataSet object by setting the RELATIONS-ACTIVE attribute on the ProDataSet object handle. All data-relations in a ProDataSet object are active by default.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Data-relation object handle

Deactivate an individual data-relation in a ProDataSet object when you want a FILL operation to load data into a ProDataSet member buffer using the individual buffer’s query. Likewise, you can reactivate a data-relation in a ProDataSet object after completing a FILL operation to use the data-relation for traversing the data after the data is loaded.

When the AVM encounters an inactive relation (or the last child buffer in the relation tree), during a FILL operation on a ProDataSet buffer object handle, the AVM does not fill the child buffers of that relation. When the AVM encounters an inactive relation during a FILL operation on a ProDataSet object handle, it treats the first child buffer of the inactive relation as a top-level table (including all rows from its data source) and fills each child buffer based on the data relation’s query. If you do not want the AVM to treat the first child buffer of the inactive relation as a top-level table, set the FILL-MODE of that buffer to NO-FILL. The AVM does not fill any of the child buffers.
If the AVM encounters an inactive relation while navigating a ProDataSet object, it does not prepare or open a dynamic query for the child table, even if there is a browse associated with the relation’s query. If you want to access the child temp-table, you must do so through a separate query, a FOR EACH statement, or some other standard ABL construct in your application code.

When you reactivate data-relations, the AVM does not automatically resynchronize the hierarchy of queries on buffers below the newly active relation. If you want to resynchronize the related buffers, use the SYNCHRONIZE( ) method on the parent buffer.

### ACTOR attribute

Returns the value of the actor attribute for the SOAP-header-entryref object as a URL. Identifies the recipient of a header element.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SOAP-header-entryref object handle

If the SOAP-header-entryref object does not contain an actor attribute, this attribute returns the empty string.

### ADD-BUFFER( ) method

Adds one new buffer to a query object or dynamic ProDataSet object, without affecting the other buffers, if any.

Use the SET-BUFFERS( ) method to remove all prior buffers and set all buffers for the object at the same time.

**Return type:** LOGICAL  
**Applies to:** ProDataSet object handle, Query object handle

**Syntax**

```
ADD-BUFFER ( buffer )
```

**buffer**

A handle to a buffer, or a CHARACTER expression that evaluates to the name of a buffer that the AVM searches for at run time.

**Note:** The maximum number of buffers per query is 18.

The following is an example:

```
```
ADD-CALC-COLUMN( ) method

Creates a browse column from the specified properties and returns the handle of the new column. This method can be used only after the browse’s query attribute has been set.

Return type: HANDLE

Applies to: BROWSE widget

Syntax

```
ADD-CALC-COLUMN( datatype-exp, format-exp, initial-value-exp, label-exp [ , pos [ , widget-type ] ] )
```

**datatype-exp**

Character expression specifying the data type. Valid values are "CHARACTER", "DATE", "DECIMAL", "INTEGER", "INT64", or "LOGICAL".

**format-exp**

Character expression specifying the column’s format.

**initial-value-exp**

Character expression specifying the initial value. This may be a null string.

**label-exp**

Character expression specifying the column’s label.

**pos**

The optional integer value position of the browse column. If \( pos = 2 \), the column is the second column. If the position is not specified or the position is invalid, the new column is added at the end of the columns.

**widget-type**

An optional character expression specifying the widget type of the column. Valid values are "COMBO-BOX", "DROP-DOWN", "DROP-DOWN-LIST", "FILL-IN" and "TOGGLE-BOX". The default value is "FILL-IN".

If **datatype-exp** is not "LOGICAL", specifying "TOGGLE-BOX" as the widget type generates a run-time error.

The **widget-type** parameter is ignored in character mode.

The following is an example of adding a column in the browse’s fifth position using this method:

```
```

The ADD-CALC-COLUMN( ) method may be used on a static browse as well as on a dynamic browse.
If the browse is already displayed, the REFRESH( ) method should be applied to the browse after columns are added using ADD-CALC-COLUMN( ). This will initially populate the viewport for the calculated column. The ROW-DISPLAY trigger would normally populate the column, but when ADD-CALC-COLUMN is being executed, the ABL calc-column handle is not yet set and, thus, cannot initially populate it.

### ADD-COLUMNS-FROM( ) method

Creates a browse column for each field found in the specified buffer or table. If a field is found that already has a corresponding browse column created, it is ignored. This method can be used only after the browse’s query attribute has been set.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
ADD-COLUMNS-FROM( buffer-handle | table-name-exp [, except-list ] )
```

- **buffer-handle**
  
  The handle of a buffer associated with the browse’s query.

- **table-name-exp**
  
  The name of a table associated with the browse’s query.

- **except-list**
  
  An expression that evaluates to a comma-separated list of field names to be excluded from the browse. Do not include the table name with these field names, and do not include spaces between field names.

The following is an example of adding browse columns from the Invoice table, excluding the fields, Amount and Total-Paid:

```
DEFINE VARIABLE ExcList AS CHARACTER INITIAL "Amount,Total-Paid".
.. .
```

The ADD-COLUMNS-FROM( ) method may be used on a static browse as well as a dynamic browse. When used on a static browse, the browse will become a NO-ASSIGN browse (you must make the database updates).

A dynamic browse column’s validation expression is restricted. It may not contain a CAN-FIND function. To reference the field, the FRAME-VALUE function must be used.

To create a combo-box or toggle-box browse column for a buffer-field, specify the widget type in the buffer-field’s VIEW-AS attribute. A buffer-field’s VIEW-AS attribute setting remains in effect for subsequent columns created for that buffer-field, until you change the attribute setting, and changing the attribute setting does not affect previously created columns. (The VIEW-AS attribute has no effect in character mode.)
ADD-EVENTS-PROCEDURE( ) method
(Windows only; Graphical interfaces only)

Adds an external procedure to the list that the AVM searches for event procedures to handle ActiveX control events.

**Return type:** LOGICAL

**Applies to:** CONTROL-FRAME widget

**Syntax**

```
ADD-EVENTS-PROCEDURE( procedure-handle )
```

**procedure-handle**

A handle to a persistent procedure or an otherwise active procedure on the call stack.

By default, the AVM searches the external procedure that created the current control-frame for the event procedure to handle an ActiveX control event. This method allows you to specify alternative procedure (.p and .w) files to search for the event handler.

When the AVM receives an ActiveX event, it searches for the event handler in order of the most recent procedure added to the search list and ends the search with the external procedure that created the control-frame. You can override an existing procedure by adding a different one to the search list. The AVM always uses the event handler in the most recently added procedure.

If the method succeeds in adding the procedure to the list, it returns TRUE. Otherwise, it returns FALSE.

---

ADD-FIELDS-FROM( ) method

Copies the field definitions from the specified source table to a temp-table. It is intended for use when a temp-table represents a join. If it finds fields that are already in the temp-table, it ignores them.

This method cannot be called after TEMP-TABLE-PREPARE( ) has been called unless CLEAR( ) is called first.

**Return type:** LOGICAL

**Applies to:** Temp-table object handle

**Syntax**

```
ADD-FIELDS-FROM( { source-buffer-handle-exp | source-table-name-exp } [ , except-list-exp ] )
```

**source-buffer-handle-exp**

An expression that evaluates to a buffer handle from which to copy the field definitions.

**source-table-name-exp**

An expression that evaluates to a table name from which to copy the field definitions.
except-list-exp

A character expression that evaluates to a comma-separated list of field names to be excluded from the new table definition.

The following example fragment creates a join temp-table from the Customer and Order tables:

```
DEFINE VARIABLE tth AS HANDLE NO-UNDO.
CREATE TEMP-TABLE tth.
tth:ADD-FIELDS-FROM("Customer").
tth:ADD-FIELDS-FROM("Order").
tth:TEMP-TABLE-PREPARE("cust-ord").
...
```

The following fragment creates a temp-table from the Customer table except for the SalesRep field:

```
tth:ADD-FIELDS-FROM("Customer", "SalesRep").
```

Note: There is a limit to the number of fields that can be accommodated in a temp-table object. The limit depends on how large the field information (initial value, validate information, help messages, etc.) is, but you should plan on a limit of approximately 1000 fields.

This method does not create any indexes. Either indexes must be added specifically through one of the ADD-INDEX methods, or a default index is created.

**ADD-FIRST() method**

Adds one or more items to the top of a combo box or selection list.

**Return type:** LOGICAL

**Applies to:** BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

**Syntax**

```
ADD-FIRST ( \{ item-list | label , value \} )
```

**item-list**

A character-string expression that represents one or more items, delimiter-separated.

**label**

A character-string expression that represents the label of a label-value pair.
ADD-HEADER-ENTRY( ) method

The value the AVM assigns to the field or variable if the user selects the corresponding label.

The delimiter is the value of the DELIMITER attribute, which defaults to comma. If the SORT attribute is TRUE, the AVM sorts new items by label before adding them to the widget. If the operation is successful, ADD-FIRST returns TRUE.

If the widget’s entries consist of single items, each call to ADD-FIRST can add multiple entries. If the widget’s entries consist of label-value pairs, each call to ADD-FIRST can add one entry.

For browses, this method applies only to combo-box browse columns.

The following examples modify widgets whose entries consist of single items:

- `return-code = my-widget-hdl:ADD-FIRST("Seoul").`
- `return-code = my-widget-hdl:ADD-FIRST("Bogota, Seoul, Los Angeles").`

The following example modifies a combo-box widget of type INTEGER whose entries consist of label-value pairs:

ADD-HEADER-ENTRY( ) method

Creates a new entry in a SOAP-header object’s list of entries and associates the new entry with an existing SOAP-header-entry-ref object. The method returns the handle to the new entry.

Return type: LOGICAL
Applies to: SOAP-header object handle

Syntax

```
ADD-HEADER-ENTRY( header-entryref )
```

header-entryref

The handle to the new SOAP-header-entry-ref object.

Following is an example of adding a SOAP-header-entry-ref object to a SOAP-header object:
ADD-INdex-Field( ) method

Adds the specified field to the specified index of a temp-table. It requires the named index to be added first.

This method cannot be called after TEMP-TABLE-PREPARE( ) has been called unless CLEAR( ) is called first.

Return type: LOGICAL
Applies to: Temp-table object handle

Syntax

ADD-INdex-Field(index-name-exp, field-name-exp [, mode-exp ])

index-name-exp
A character expression that evaluates to the name of the index to which the field is being added.

field-name-exp
A character expression that evaluates to the name of the field to add to the index.

mode-exp
An expression that evaluates to desc if it is descending or asc if it is ascending. The default is asc.

The following example fragment adds to a temp-table a new unique primary index field with two components, the first ascending, the second descending:

tth:ADD-FIELDS-FROM("Customer", "SalesRep").
tth:ADD-NEW-INDEX("abidx", TRUE, TRUE).
tth:ADD-INdex-Field("abidx", "abfield1").
tth:ADD-INdex-Field("abidx", "abfield2", "desc").
...

ADD-LAST( ) method

Adds one or more items to the bottom of a combo box, radio set, or selection list.
ADD-LAST( ) method

**Return type:** LOGICAL

**Applies to:** BROWSE widget (column), COMBO-BOX widget, RADIO-SET widget, SELECTION-LIST widget

This is the syntax for a combo-box, selection-list, or browse column.

Syntax (combo-box, selection-list, or browse column)

```
ADD-LAST ( { item-list | label , value } )
```

**item-list**
A character-string expression that represents one or more items, delimiter-separated.

**label**
A character-string expression that represents the label of a label-value pair.

**value**
The value the AVM assigns to the field or variable if the user selects the corresponding label.

**Note:** If the widget’s entries consist of single items, use `item-list`. If the widget’s entries consist of label-value pairs, use `label` and `value`.

For combo boxes and selection lists, the delimiter is the value of the DELIMITER attribute, which is comma by default. Also, if the SORT attribute is TRUE, ADD-LAST sorts the new items by label before adding them to the widget.

For browsers, this method applies only to combo-box browse columns.

This is the syntax for a radio-set.

Syntax (radio-set)

```
ADD-LAST ( label , value )
```

**label**
A character-string expression that represents the label of a label-value pair.

**value**
An integer expression that represents the value of a label-value pair. When the radio set appears, if the user selects `label`, the AVM assigns `value` to the corresponding field or variable.

For radio sets, if the AUTO-RESIZE attribute is TRUE; the size of the radio set changes. Otherwise, the radio set is clipped.

For all applicable widgets, if the operation is successful, ADD-LAST returns TRUE.
Note: If the widget’s entries consist of single items, each call to ADD-LAST can add multiple entries. If the widget’s entries consist of label-value pairs, each call to ADD-LAST can add one entry.

The following examples modify widgets whose entries consist of single items:

\[
\begin{align*}
\text{return-code} &= \text{my-combo-box-hdl:ADD-LAST("Seoul").} \\
\text{return-code} &= \text{my-sel-list-hdl:ADD-LAST("Bogota, Seoul, Los Angeles").}
\end{align*}
\]

The following example modifies a combo-box widget of type INTEGER whose entries consist of label-value pairs:

\[
\text{return-code} = \text{my-widget-hdl:ADD-LAST("Bogota", 15).}
\]

---

**ADD-LIKE-COLUMN( ) method**

Creates a browse column from the specified field and returns its handle. This method can be used only after the browse’s query attribute has been set.

**Return type:** HANDLE  
**Applies to:** BROWSE widget

**Syntax**

\[
\text{ADD-LIKE-COLUMN( field-name-exp | buffer-field-handle} \\
\text{\[ , pos \[ , widget-type \] ] )}
\]

*field-name-exp*

The name of a field in one of the buffers associated with the browse’s query. If the query is a join, the name must be qualified with the database name.

*buffer-field-handle*

The handle of a buffer-field from a buffer associated with the browse’s query.

*pos*

The optional integer value position of the browse column. If \(pos = 2\), the column is the second column. If the position is not specified or the position is invalid, the new column is added at the end of the columns.

*widget-type*

An optional character expression specifying the widget type of the column. Valid values are “COMBO-BOX”, “DROP-DOWN”, “DROP-DOWN-LIST”, “FILL-IN”, and “TOGGLE-BOX”. The default value is “FILL-IN”.

1291
The widget-type parameter is ignored in character mode.

A widget type of “COMBO-BOX” or “DROP-DOWN-LIST” is valid only when the buffer-field’s data type is CHARACTER, DATE, DECIMAL, INTEGER, INT64 or LOGICAL. A widget type of “DROP-DOWN” is valid only when the buffer-field’s data type is CHARACTER. A widget type of “TOGGLE-BOX” is valid only when the buffer-field’s data type is LOGICAL. If the widget type is not valid for the buffer-field’s data type, the AVM generates a run-time error.

If not specified, the AVM creates the browse column based on the widget type specified in the buffer-field’s VIEW-AS attribute. (The VIEW-AS attribute has no effect in character mode.)

The ADD-LIKE-COLUMN( ) method can be used on a static browse as well as a dynamic browse. When used on a static browse, the browse will become a NO-ASSIGN browse (you must make the database updates).

A dynamic browse column’s validation expression is restricted. It may not contain a CAN-FIND function. To reference the field, the FRAME-VALUE function must be used.

The following is an example of adding the Customer number field to the browse:

```
ColHdl = BrwsHndl:ADD-LIKE-COLUMN("Customer.CustNum").
```

ADD-LIKE-FIELD( ) method

Adds a field, like the specified source field, to the temp-table.

This method cannot be called after TEMP-TABLE-PREPARE( ) has been called unless CLEAR( ) is called first.

**Return type:** LOGICAL  
**Applies to:** Temp-table object handle

**Syntax**

```
ADD-LIKE-FIELD( field-name-exp ,
    source-buffer-field-handle-exp | source-db-field-name-exp )
```

**field-name-exp**

A character expression that evaluates to the name of the field to be created in the temp-table.

**source-buffer-field-handle-exp**

A character expression that evaluates to a buffer-field handle from which to copy the field.

**source-db-field-name-exp**

A character expression that evaluates to a database field name from which to copy the field. The table name must be qualified with the database name.
The following example fragments add a field to a temp-table, the first from a named source and the second from a buffer-field handle source:

```plaintext
tth:ADD-LIKE-FIELD("ordno","Order.OrderNum").

tth:ADD-LIKE-FIELD(bfh:NAME, bfh).
```

**Note:** There is a limit to the number of fields that can be accommodated in a temp-table object. The limit depends on how large the field information (initial value, validate information, help messages, etc.) is, but you should plan on a limit of approximately 1,000 fields.

---

### ADD-LIKE-INDEX( ) method

Adds an index, like the specified source index, to the temp-table.

This method cannot be called after TEMP-TABLE-PREPARE( ) has been called unless CLEAR( ) is called first.

**Return type:** LOGICAL  
**Applies to:** Temp-table object handle

**Syntax**

```plaintext
ADD-LIKE-INDEX( index-name-exp , source-index-name-exp  
               { , source-buffer-handle-exp | source-db-table-name-exp }  )
```

**index-name-exp**

A character expression that evaluates to the name of the index to which the source index is being copied.

**source-index-name-exp**

A character expression that evaluates to the name of the index in the source table that is being copied to the temp-table.

**source-buffer-handle-exp**

A character expression that evaluates to a buffer handle from which to copy the index.

**source-db-table-name-exp**

A character expression that evaluates to a database table name from which to copy the index.

The following example fragment adds a new index to a temp-table like the name index in the Customer table:
ADD-NEW-FIELD( ) method

Adds a field with the specified properties to the temp-table. Additional properties can be manipulated by creating a buffer-field object for this field.

This method cannot be called after TEMP-TABLE-PREPARE( ) has been called unless CLEAR( ) is called first.

Return type: LOGICAL
Applies to: Temp-table object handle

Syntax

```
```

**field-name-exp**

A character expression that evaluates to the name of the field to be created in the temp-table.

**datatype-exp**

A character expression that evaluates to the data type of the specified field.

**extent-exp**

An integer expression specifying the extent of an array. If extent-exp is 0, 1 or the Unknown value (?), it is ignored.

**format-exp**

A character expression that evaluates to the data format for the defined data type. If format-exp is "" or the Unknown value (?), it is ignored and the default format of the specified data type is used.

**initial-exp**

An expression that evaluates to the initial value of the defined field. initial-exp can be any compatible data type, but is usually character. If initial-exp is not entered, the default for the data type is used.

**label-exp**

An optional character expression that evaluates to the label of the defined field. If you do not specify a value, or you pass the Unknown value (?), label-exp defaults to the value of the field-name-exp parameter.
ADD-NEW-INDEX( ) method

COLUMN-LABEL-EXP

An optional character expression that evaluates to the label of the column associated with the defined field. If you do not specify a value, or you pass the Unknown value (?), COLUMN-LABEL-EXP defaults to the value of the LABEL-EXP parameter (or the FIELD-NAME-EXP parameter, if the LABEL-EXP parameter is not specified).

The following example fragment adds a new character field called “abfield” which is initialized to “abc” to a temp-table:

```
tth:ADD-NEW-FIELD("abfield","char",0,,"abc").
```

Note: There is a limit to the number of fields that can be accommodated in a temp-table object. The limit depends on how large the field information (initial value, validate information, help messages, etc.) is, but you should plan on a limit of approximately 1,000 fields.

ADD-NEW-INDEX( ) method

Adds a new empty index with the specified name to the temp-table. Index components must be added with the ADD-INDEX-FIELD( ) method.

This method cannot be called after TEMP-TABLE-PREPARE( ) has been called unless CLEAR( ) is called first.

Return type: LOGICAL

Applies to: Temp-table object handle

Syntax

```
ADD-NEW-INDEX( index-name-exp [, , unique-exp [, , primary-exp [, , wordix-exp ] ] ] )
```

INDEX-NAME-EXP

A character expression that evaluates to the name of the created index.

UNIQUE-EXP

A logical expression that evaluates to TRUE if this index is unique.

PRIMARY-EXP

A logical expression that evaluates to TRUE if this is the primary index.

WORDIX-EXP

A logical expression that evaluates to TRUE if this is a word index.

The following example fragment adds to a temp-table a new unique primary index field with two components, the first ascending, the second descending:
ADD-RELATION( ) method

Adds a data-relation object for a pair of parent and child buffers to a dynamic ProDataSet object.

**Return type:** HANDLE

**Applies to:** ProDataSet object handle

**Syntax**

```plaintext
ADD-RELATION ( parent-buffer-handle, child-buffer-handle,
               [ pairs-list [, reposition-mode [, nested [, not-active [, recursive
```

**parent-buffer-handle**

A handle to the parent buffer in the data-relation object.

**child-buffer-handle**

A handle to the child buffer in the data-relation object.

**pairs-list**

An expression that evaluates to a comma-separated list of parent-field, child-field pairs describing the relationship between parent and child buffers in the data-relation object using the following syntax:

**Syntax**

```plaintext
parent-field1, child-field1 [, parent-fieldn, child-fieldn ] ...)
```

The first field in the pair is from the parent buffer, the second field is from the child buffer. When filling the ProDataSet object, the AVM retrieves data for the child buffer based on an equality match between all pairs of fields unless the Data-Relation is deactivated or there is an explicit query definition for the data source of the child buffer.

You can define a query for the data source of the child buffer, or you can supply custom logic in response to FILL events that take over complete responsibility for filling one level of the ProDataSet object. In these cases, the **pairs-list** is not used.

**reposition-mode**

The reposition mode of the relation between the parent and child temp-tables. If TRUE, the relation mode is REPOSITION. If FALSE, the relation mode is SELECTION. The default value is FALSE.
When the relation mode is SELECTION, the method fills the child temp-table of the data-relation object with all records related to the current parent. When the relation mode is REPOSITION, the relation is effectively ignored during a FILL, and the child of the relation is treated as if it were a top-level buffer.

When navigating a filled ProDataSet object with a SELECTION relation, related data is filtered as it is browsed. This means the child query of the relation is filtered to make available only children of the current parent, and the query is re-opened each time the parent table is repositioned. When navigating a filled ProDataSet object with a REPOSITION relation, the child table query is always set to match all the rows in the child table, and is not re-opened when the parent changes. Only the buffer for the child is repositioned to the matching child for the current parent.

**nested**

A LOGICAL expression where TRUE directs the AVM to nest child rows of ProDataSet buffers within their parent rows when writing the XML representation of data. This also causes the XML Schema definitions for the related temp-tables to be nested. When FALSE, all child rows are written after all parent rows are written. The default value is FALSE.

**not-active**

An optional LOGICAL expression where FALSE causes the data-relation to be inactive. This allows you to have two relations between the same two ProDataSet temp-table buffers, but only have one active relation at a time.

**recursive**

An optional LOGICAL expression where TRUE causes the data-relation to be filled recursively. This mode instructs the ProDataSet FILL to load self-referencing elements. That is, an element can reference a child element that already either directly or indirectly references the parent element in the hierarchy. Examples of this hierarchy are bill-of-materials parent/child tables or organization chart manager/employee relationship tables.

**foreign-key-hidden**

An optional LOGICAL expression where TRUE directs the AVM to omit foreign key fields in nested data-relations when writing the XML representation of data. This also causes the XML Schema definition for the ProDataSet to indicate that the foreign key fields are optional. Since the parent record in a nested relationship contains the foreign key, suppressing it in the nest child record is efficient. If this option is used, the NESTED argument must be TRUE.

When working with large ProDataSets, omitting foreign keys in nested child records can yield smaller XML documents, more efficient network transfers, and performance gains with the READ-XML( ) and WRITE-XML( ) methods.

Care must be taken when deciding to use this feature. The READ-XML( ) method automatically populates foreign keys in nested child records with the values in the outer parent record when the foreign key is omitted from the XML document. Unless you are sure that the receiver of the XML document will do the same, you should not use this option in your nested data-relations.
ADD-SCHEMA-LOCATION( ) method

For example, while .NET can read this XML document and populate an ADO .NET
DataSet, it will create rows in the child DataTable with a null value for the foreign key
fields.

See also: FOREIGN-KEY-HIDDEN attribute, RECURSIVE attribute

ADD-SCHEMA-LOCATION( ) method

An XML Schema file location is specified by providing a pair of values: a namespace and a
physical location. This method allows you to specify that value pair. The XML Schema file is
used by an X-document or SAX-reader object to validate XML content.

Return type: LOGICAL
Applies to: X-document object handle, SAX-reader object handle

Syntax

\[
\text{ADD-SCHEMA-LOCATION( targetNamespace, location )}
\]

targetNamespace

A CHARACTER expression evaluating to the target namespace of the schema, or an
empty string (""") or the Unknown value (?) if the location doesn’t contain a namespace.

location

A CHARACTER expression evaluating to the location of the XML Schema file.

Provides the location of an XML Schema file for the parser by specifying the namespace and
physical location of the XML Schema file.

You can call this method more than once to create a list of schema locations.

Note that namespace and XML Schema file locations specified programatically with this
method take precedence over namespaces or schemas declared in XML documents or imported
elements.

This method and the SCHEMA-LOCATION attribute are both used for setting the XML
Schema file location. This method is added for convenience.

ADD-SOURCE-BUFFER( ) method

Adds a database buffer to a dynamic Data-source object at run time.

Return type: LOGICAL
Applies to: Data-source object handle

Syntax

\[
\text{ADD-SOURCE-BUFFER( buffer-handle, key-fields )}
\]
ADD-SUPER-PROCEDURE( ) method

Associates a super procedure file with a procedure file or with the current ABL session. When a procedure file invokes an internal procedure or a user-defined function, ABL searches for it, among other places, in the super procedures (if any) of the procedure file and of the current ABL session. The procedure-search option determines which procedures are searched.

For more information on the rules that ABL uses to search for internal procedures and user-defined functions, see the “Search rules” section on page 1302. For a sample program that uses the ADD-SUPER-PROCEDURE method, see the reference entry for the RUN SUPER statement.

Returns FALSE for a Web service procedure.

**Return type:** LOGICAL  
**Applies to:** Procedure object handle, SESSION system handle

**Syntax**

```
ADD-SUPER-PROCEDURE ( super-proc-hdl [, proc-search ] )
```

**super-proc-hdl**

The handle of a running persistent procedure that you want to make a super procedure of the local procedure or of the current ABL session.

ADD-SUPER-PROCEDURE returns FALSE if `super-proc-hdl` is not a valid handle, or if the AVM detects that the method was not successful. Otherwise, the method returns TRUE.

**proc-search**

Optional expression that determines which super procedures are searched when `super-proc-hdl` invokes RUN SUPER or the SUPER function. Valid values are SEARCH-SELF (or 1) or SEARCH-TARGET (or 2). The default, if there is no entry, is SEARCH-SELF. The search commences in the super procedure stack of `super-proc-hdl`.

Consider the following:

- SEARCH-SELF starts searching in the procedure file that initiated the current internal procedure or user-defined function.

- SEARCH-TARGET starts searching the super procedures of the procedure file that originally invoked the current internal procedure or user-defined function (the procedure with the original RUN statement). If the procedure was RUN . . . IN
**ADD-SUPER-PROCEDURE()** method

`procedure-handle`, `SEARCH-TARGET` searches the super procedures of `procedure-handle`.

- A given `super-proc-hdl` can be added as either `SEARCH-TARGET` or `SEARCH-SELF`, but cannot be added as both. If `proc-search` is set for a `super-proc-hdl`, then any attempt to change its value generates a run-time warning, but the `ADD-SUPER-PROCEDURE()` method succeeds. The warning message “Changing proc-search-string for procedure <p-name> from <string> to <string>” is presented to indicate that the application is using an instance of a given super procedure in an inconsistent manner. This warning message can be suppressed by using the `SESSION:SUPPRESS-WARNINGS` attribute. In addition, the warning message can be avoided by creating two instances of `super-proc-hdl`, one identified as `SEARCH-TARGET` and the other identified as `SEARCH-SELF`.

**Associating a super procedure with a procedure**

The following example associates a super procedure with the current procedure:

```
```

The following example:

- Associates a super procedure with a procedure that the current procedure is working for.
- Requests that the super procedure stack associated with local-proc-hdl be searched rather than the stack associated with my-super-proc-hdl when RUN SUPER is invoked in `super-proc-hdl`.

```
```

The procedure to which you add a super procedure is called the **local procedure** of the super procedure.

**Associating a super procedure with the current ABL session**

The following example associates a super procedure with the current ABL session:

```
```

When you do this, the AVM automatically associates the super procedure with all the session’s procedures—persistent and nonpersistent—without your having to change their code in any way. This technique lets you replace occurrences of the following:

```
THIS-PROCEDURE:ADD-SUPER-PROCEDURE(super-proc-hdl).
```

In individual procedures with a single occurrence of the following:
Super procedure stacking

You can associate multiple super procedures with a single local procedure or with the current ABL session. When you do this, the AVM stores (and later on, searches) the corresponding procedure handles in last in first out (LIFO) order—the handle of the most recently added super procedure first, the handle of the next most recently added super procedure second, etc.

A collection of super procedure handles associated with a local procedure or with the current ABL session is called a super procedure stack. The handle of the most recently added super procedure occupies the top of the stack.

If you add a super procedure that is already in the stack, the AVM removes the previous occurrence of the super procedure handle from the stack and adds the new occurrence to the top of the stack—all without reporting an error.

Super procedure chaining

You can add a super procedure to a super procedure. For example, imagine the following scenario:

1. A, B, and C are procedure files running persistently.
2. B is a super procedure of A.
3. C is a super procedure of B.

B is a super procedure (of A) and has a super procedure (C).

When you add a super procedure to a super procedure, the result is a super procedure chain, each link of which consists of two elements: a local procedure and its super procedure. When the AVM searches a super procedure chain, it does not proceed to the next link unless the current link’s super procedure element explicitly invokes its super version (by using the RUN SUPER statement or the SUPER function).

For example, imagine the following scenario:

1. A, B, and C, and X are procedure files running persistently.
2. add-record is an internal procedure different versions of which reside in A, B, and C.
3. B is a super procedure of A.
4. C is a super procedure of B.
5. X says RUN add-record IN A.

The following events occur:

1. The AVM searches A for add-record and runs it if found.
2. If and only if A’s add-record exists and says RUN SUPER, the AVM searches B for add-record and runs it if found.
Note: If A does not contain add-record, the following events occur: If B contains add-record, the AVM runs it. If B does not contain add-record, the AVM does not search for add-record in C.

3. If and only if B’s add-record exists and says RUN SUPER, the AVM searches C for add-record and runs it if found.

In this way, the AVM avoids excessive and possibly circular searching.

Search rules

The AVM searches for internal procedures and user-defined functions depending on how the internal procedure or user-defined function is invoked. The search rules illustrated in the first three cases assume that all the super procedures were added with no proc-search value or with a proc-search value of SEARCH-SELF. The fourth case illustrates the search process when a super procedure is added with a proc-search value of SEARCH-TARGET.

Case 1: When the AVM encounters a statement like the following:

```
RUN add-record('Customer').
```

The AVM searches for add-record as follows:

1. As an internal procedure in the local procedure
2. As an internal procedure in a super procedure of the local procedure
3. As an internal procedure in a super procedure of the ABL session
4. As an external procedure file add-record.p or add-record.r

Case 2: When the AVM encounters a statement like the following:

```
RUN add-record IN my-proc-hdl('Customer').
```

The AVM searches for add-record as follows:

1. As an internal procedure in my-proc-hdl
2. As an internal procedure in a super procedure of my-proc-hdl
3. As an internal procedure in a super procedure of the ABL session

Case 3: When the AVM encounters a statement like the following:

```
add-record('Customer').
```

The AVM searches for add-record as follows:

1. As a user-defined function in the local procedure
2. As a user-defined function in a super procedure of the local procedure

3. As a user-defined function in a super procedure of the ABL session

Note: The rules of Case 3 apply whether or not the user-defined function’s declaration (function prototype) includes the IN proc-hdl option. In Case 3, proc-hdl represents the local procedure. For more information on function prototypes of user-defined functions, see OpenEdge Getting Started: ABL Essentials.

Search rules for SEARCH-TARGET

Case 4: A procedure, main.p, has added three super procedures, S1, S2, and S3 (in that order). Each of these super procedures has added its own super procedures, S1A, S1B, S2A, S2B, S3A, S3B. The procedure, add-record, exists in three places: in S1, in S2 where it contains a RUN SUPER statement, and in S2A.

When the AVM encounters a statement like "RUN add-record('customer').", it searches for the add-record procedure:

1. As an internal procedure in the local procedure, main.p

2. Then as an internal procedure in S3, and then in S2 where it is found

The following code for main.p shows the differences in the initial setup of this case, which compares the use of no proc-search value (Instance 1) with the use of a value of SEARCH-TARGET (Instance 2):

```abl
/* main.p */
DEFINE VARIABLE h AS HANDLE NO-UNDO.

RUN s1.p PERSISTENT SET h.
THIS-PROCEDURE:ADD-SUPER-PROC(h).

RUN s2.p PERSISTENT SET h.
/* Instance 1
THIS-PROCEDURE:ADD-SUPER-PROC(h).
*/
/* Instance 2 */
THIS-PROCEDURE:ADD-SUPER-PROC(h, SEARCH-TARGET).

RUN s3.p PERSISTENT SET h.
THIS-PROCEDURE:ADD-SUPER-PROC(h).

RUN add-record.
```

If S2 was added with no proc-search value (Instance 1, commented out) or with a proc-search value of SEARCH-SELF, when RUN SUPER is executed within add-record in S2, the AVM starts searching in S2A, which is next in the search stack of the super procedure, S2.

If S2 was added with a proc-search value of SEARCH-TARGET (Instance 2, as executed), when RUN SUPER is executed within add-record in S2, the AVM starts searching in S1, which is next in the search stack of the local procedure, main.p.

Note: The search commences with the super procedure following super-proc-hdl in the local procedure’s search stack.
**ADM-DATA attribute**

An arbitrary string value associated with a persistent procedure.

**Note:** The ADM-DATA attribute is for use by the OpenEdge ADM only.

<table>
<thead>
<tr>
<th>Data type</th>
<th>CHARACTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>Readable/Writeable</td>
</tr>
<tr>
<td>Applies to</td>
<td>Buffer object handle, Buffer-field object handle, Data-relation object handle, Data-source object handle, Procedure object handle, ProDataSet object handle, Query object handle, SAX-attributes object handle, SAX-reader object handle, SOAP-header object handle, SOAP-header-entryref object handle, SOURCE-PROCEDURE system handle, Stream object handle, TARGET-PROCEDURE system handle, Temp-table object handle, THIS-PROCEDURE system handle</td>
</tr>
</tbody>
</table>

**AFTER-BUFFER attribute**

Returns the handle to the default buffer of the after-image table that corresponds to the buffer of the before-image table currently associated with this buffer handle.

<table>
<thead>
<tr>
<th>Data type</th>
<th>HANDLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>Readable</td>
</tr>
<tr>
<td>Applies to</td>
<td>Buffer object handle</td>
</tr>
<tr>
<td>See also</td>
<td>BEFORE-BUFFER attribute</td>
</tr>
</tbody>
</table>

**AFTER-ROWID attribute**

Returns the ROWID of the row in the after-image table that is the current version of the row in the before-image table currently associated with this buffer handle. This row can be a new or modified row.

<table>
<thead>
<tr>
<th>Data type</th>
<th>ROWID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>Readable</td>
</tr>
<tr>
<td>Applies to</td>
<td>Buffer object handle</td>
</tr>
</tbody>
</table>

This attribute is set to the Unknown value (?) for rows that have been deleted.

| See also      | BEFORE-ROWID attribute |

**AFTER-TABLE attribute**

Returns the handle of the after-image table that corresponds to the before-image table currently associated with this temp-table handle.
ALLOW-COLUMN-SEARCHING attribute

(Windows only)

Setting this attribute to TRUE allows column searching for browses.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BROWSE widget

The default is FALSE for read-only static browses. The default is TRUE for dynamic browses and static updateable browses.

If ALLOW-COLUMN-SEARCHING is set to TRUE, the START-SEARCH and END-SEARCH events will be triggered when a search is initiated and completed.

ALWAYS-ON-TOP attribute

(Windows only)

Indicates whether the window should remain on top of all windows, even windows belonging to other applications.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: WINDOW widget

This attribute differs from the TOP-ONLY attribute, which indicates that the window should remain on top of all windows of the ABL session. Windows that have the ALWAYS-ON-TOP attribute set are always above TOP-ONLY windows in the z-order; they are also above dialog boxes in some cases.

A window cannot have both the TOP-ONLY and ALWAYS-ON-TOP attributes set. Setting the ALWAYS-ON-TOP attribute to TRUE will set the TOP-ONLY attribute to FALSE. The default value of the ALWAYS-ON-TOP attribute is FALSE.

.NET forms also have a TopMost property that also indicates whether the form should remain on top of all forms of all running applications. Windows allows you to set both an ABL window as an ALWAYS-ON-TOP window and a .NET form as a TopMost form. The window and form will each stay on top of all other windows on the desktop, because Windows maintains two categories of windows—topmost windows and non-topmost windows. All topmost windows appear in front of all non-topmost windows, and you can shuffle the Z-order of the two groups of windows relative to their siblings.
AMBIGUOUS attribute

Indicates whether more than one record matched the FIND predicate.

Data type: LOGICAL
Access: Readable
Applies to: Buffer object handle

If AMBIGUOUS is TRUE, the most recent unique find on the buffer failed because more than one record matched the FIND predicate. Otherwise, AMBIGUOUS is FALSE.

APPEND-CHILD( ) method

Appends a node as the last child node of this XML document or element node. Connects a node into the document structure after the node has been created with the CREATE-NODE( ) or CREATE-NODE-NAMESPACE( ) method, cloned with the CLONE-NODE( ) method, or disconnected with the REMOVE-NODE( ) method. This has no effect on the node reference.

If the node is already in the tree, it is disconnected from its present location and then connected at the specified location.

Return type: LOGICAL
Applies to: X-document object handle, X-noderef object handle

Syntax

APPEND-CHILD( x-node-handle )

x-node-handle

The handle that represents the node to append to this XML document or element node. x-node-handle must refer to a node in this document. You cannot use APPEND-CHILD( ) to move a node from one document to another.

The following code fragment demonstrates creating a node in a tree with the name and value of a field:

```plaintext
hDoc:CREATE-NODE(hNoderef, bufField:NAME, "ELEMENT").
hNoderefParent:APPEND-CHILD(hNoderef).
hDoc:CREATE-NODE(hText, "", "TEXT").
hText:NODE-VALUE = STRING(bufField:BUFFER-VALUE).
hNoderef:APPEND-CHILD(hText).
```
APPL-ALERT-BOXES attribute

Directs application messages to alert boxes or the default message area.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: SESSION system handle

If the APPL-ALERT-BOXES attribute is TRUE, an application message produced by the MESSAGE statement is displayed in alert boxes rather than in the message area. The default value is FALSE.

APPL-CONTEXT-ID attribute

Returns the universally unique identifier (UUID) for the application context in effect for the current session, as a Base64 character string. The UUID is 22 characters in length (the two trailing Base64 pad characters are removed).

Data type: CHARACTER
Access: Readable
Applies to: AUDIT-CONTROL system handle

The value of this attribute is set by the SET-APPL-CONTEXT( ) method, and cleared by the CLEAR-APPL-CONTEXT( ) method. This value is recorded in all audit event records generated for this application context until you either clear the current application context or set a different application context.

If no application context is in effect, this method returns the Unknown value (?)..

See also: CLEAR-APPL-CONTEXT( ) method, SET-APPL-CONTEXT( ) method

APPLY-CALLBACK( ) method

Applies a callback procedure, which lets you execute a defined event without duplicating the event procedure definition.

Return type: LOGICAL
Applies to: Buffer object handle, ProDataSet object handle, Query object handle

Syntax

```
APPLY-CALLBACK( event-name )
```

event-name

The name of a defined event.

Use the SET-CALLBACK-PROCEDURE( ) method to associate an internal procedure with a callback for an object.
For more information on events, see the “Handle-based Object Events Reference” section on page 1827.

See also: GET-CALLBACK-PROC-CONTEXT( ) method, GET-CALLBACK-PROC-NAME( ) method, SET-CALLBACK-PROCEDURE( ) method

---

APPSERVER-INFO attribute

Connection parameter for the AppServer CONNECT( ) method.

- **Data type:** CHARACTER  
- **Access:** Readable/Writeable  
- **Applies to:** CODEBASE-LOCATOR system handle  

Valid only if LOCATOR-TYPE is "AppServer".

---

APPSERVER-PASSWORD attribute

Password parameter for the AppServer CONNECT( ) method.

- **Data type:** CHARACTER  
- **Access:** Readable/Writeable  
- **Applies to:** CODEBASE-LOCATOR system handle  

Valid only if LOCATOR-TYPE is "AppServer".

---

APPSERVER-USERID attribute

Userid parameter for the AppServer CONNECT( ) method.

- **Data type:** CHARACTER  
- **Access:** Readable/Writeable  
- **Applies to:** CODEBASE-LOCATOR system handle  

Valid only if LOCATOR-TYPE is "AppServer".

---

ASYNCHRONOUS attribute

Makes a dynamic invoke asynchronously. That is, the INVOKE( ) method with ASYNCHRONOUS set to TRUE does dynamically what the RUN statement with the ASYNCHRONOUS option does statically.

**Note:** If ASYNCHRONOUS is TRUE, the logic being invoked must reside on an AppServer.
**ASYNC-REQUEST-COUNT attribute**

The number of active asynchronous requests for the specified procedure or AppServer.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Procedure object handle, Server object handle

For a procedure handle, this attribute is only meaningful if PROXY and PERSISTENT are set to TRUE. In all other cases, this attribute returns zero (0).

The AVM sets this attribute to one (1) on the following handles:

- A proxy persistent procedure handle created for an initial asynchronous request
- The server handle of the AppServer where the asynchronous persistent procedure is instantiated

The AVM increments this attribute:

- On any proxy persistent procedure handle where an internal procedure defined in the specified remote persistent procedure context is executed asynchronously
- On any server handle where an internal or external procedure is executed asynchronously on the specified AppServer

The AVM decrements this attribute as part of processing the PROCEDURE-COMPLETE event for one of the associated asynchronous requests. The attribute is decremented before any associated event procedure is executed in the context of a PROCESS EVENTS, WAIT-FOR, or other I/O-blocking statement.
ASYNC-REQUEST-HANDLE attribute

A handle to an asynchronous-request object providing information on an asynchronous invoke.

**Note:** Applies only if ASYNCHRONOUS is TRUE.

- **Data type:** HANDLE
- **Access:** Read Only
- **Applies to:** Call object handle

The default is the Unknown value (?).

ATTACH-DATA-SOURCE() method

Attaches a Data-source object to a temp-table buffer in a ProDataSet object.

- **Return type:** LOGICAL
- **Applies to:** Buffer object handle

**Syntax**

```plaintext
buffer-handle:ATTACH-DATA-SOURCE ( datasource-hdl
    [ [ [ , pairs-list ] , except-fields ] , include-fields ] )
```

- **Buffer-handle**
  A handle to the temp-table buffer in the ProDataSet object.

- **Datasource-hdl**
  A handle to the Data-source object.

- **Pairs-list**
  An optional character expression that evaluates to a comma-separated list of field name pairs that specify different names in the Data-source object buffer and the ProDataSet temp-table buffer using the following syntax:

  **Syntax**
  ```plaintext
  "table1-field1,table2-field1 [,table1-fieldn,table2-fieldn ] ..."
  ```

  The order within each field name pair does not matter; each pair must contain one field name from the Data-source object buffer and one field name from the ProDataSet object buffer. If you have a field in both the Data-source object buffer and the ProDataSet object buffer with the same, and you do not want to map them to each other, you must qualify each field name with its table name.

  You can use the ATTACHED-PAIRLIST attribute to retrieve this list of field name pairs.
**except-fields**

An optional character expression that evaluates to a comma-separated list of fields in the ProDataSet object buffer that will not be populated with data from the data source (that is, fields to exclude). Use this option when it is easier to specify fields to exclude rather than include. You can specify `except-fields` or `include-fields`, but not both.

**include-fields**

An optional character expression that evaluates to a comma-separated list of fields to include in the ProDataSet object buffer, as an alternative to specifying fields to exclude in `except-fields`. Use this option when it is easier to specify fields to include rather than exclude. You can specify `include-fields` or `except-fields`, but not both. If you specify `include-fields`, you must set `except-fields` to the Unknown value (?).

See also: DETACH-DATA-SOURCE( ) method

---

**ATTACHED-PAIRLIST attribute**

Returns a comma-separated list of field name pairs for fields in a ProDataSet temp-table buffer that are mapped to corresponding fields in an attached Data-source object. This list includes only the field name pairs you specified with the most recently attached Data-source object (in the order you specified them).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** Buffer object handle

This list is formatted as a comma-separated list of field name pairs using the following syntax:

**Syntax**

```
"table1-field1,table2-field1 [,table1-fieldn,table2-fieldn ] ..."
```

If the buffer is not part of a ProDataSet object, or the buffer does not have an attached Data-source object, or you did not specify a field name pair list when you attached the Data-source object, this attribute returns the Unknown value (?).

Use the `DATA-SOURCE-COMPLETE-MAP attribute` to retrieve a list of field name pairs for all fields in a ProDataSet temp-table buffer that are mapped to corresponding fields in an attached Data-source object.

See also: ATTACH-DATA-SOURCE( ) method

---

**ATTRIBUTE-NAMES attribute**

Returns a comma-separated list of an element’s attribute names. The attribute names are contained in the XML document. If the element does not have any attributes, the empty string (""") is returned.
ATTR-SPACE attribute

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** X-noderef object handle

If hNoderef is an element node with various attributes, and anames and bname are character program variables, the following example demonstrates listing all the attributes of the XML node:

```plaintext
anames = hNoderef:ATTRIBUTE-NAMES.
REPEAT jx = 1 TO NUM-ENTRIES(anames):
  bname = ENTRY(jx, anames).
  MESSAGE "attribute-name is" bname "value is"
     hNoderef:GET-ATTRIBUTE(bname).
END.
```

**AUDIT-EVENT-CONTEXT attribute**

The audit event context for a Client-principal object. The AVM stores this application-defined audit context in the _Event-context field in the audit record created for an audit event generated by the SEAL( ) method, LOGOUT( ) method, and AUTHENTICATION-FAILED( ) method. If not specified, the _Event-context field in the audit record is left blank.

The value of this attribute cannot exceed 200 characters. You can also use this value as an alternate index for querying the audit event record.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Client-principal object handle

Once the Client-principal object is sealed, this attribute is read-only.
AUTHENTICATION-FAILED( ) method

Indicates that an unsealed Client-principal object could not be authenticated. This authentication failure signifies that the application or database user identity from the registered authentication domain is not authentic. Once invalidated, the Client-principal object’s properties cannot be changed and the object cannot be sealed.

Note: An application can use this method to invalidate an unsealed Client-principal object for any reason.

Return type: LOGICAL

Applies to: Client-principal object handle

Syntax

AUTHENTICATION-FAILED( [ reason ] )

reason

An optional character expression that specifies the reason for the authentication failure. For example, “Invalid user name or password”. The AVM sets the STATE-DETAIL attribute to this value.

If you call this method for a sealed Client-principal object, the AVM generates a run-time error.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

Calling this method generates an audit event and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.

The AVM also sets the LOGIN-STATE attribute for the Client-principal object to “FAILED”.

Use the LOGOUT( ) method to invalidate, or terminate access to, a sealed Client-principal object.

The following code fragment illustrates how to use the AUTHENTICATION-FAILED( ) method:

```
DEFINE VARIABLE hCP AS HANDLE NO-UNDO.
DEFINE VARIABLE val-ok AS LOGICAL NO-UNDO.
... CREATE CLIENT-PRINCIPAL hCp.
... val-ok = hCp:AUTHENTICATION-FAILED("Invalid username or password").
```
**AUTO-COMPLETION attribute**

*See also:* LOGIN-STATE attribute, LOGOUT( ) method, STATE-DETAIL attribute

**AUTO-COMPLETION attribute**  
*(Windows only; Graphical interfaces only)*

Specifies that the combo-box widget automatically complete keyboard input based on a potential match to items in the drop-down list.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (column), COMBO-BOX widget

When the AUTO-COMPLETION attribute is TRUE, the widget’s edit control compares the input to the items in the drop-down list. After each incremental character keystroke, the edit control searches through the items in the drop-down list for a potential match. If a potential match is found, the full item is displayed in the edit control. The automatically completed portion of the item is highlighted. You can replace the highlighted portion of the item by typing over it, or delete the highlighted portion of the item using the **DELETE** key or the **BACKSPACE** key. The default value is FALSE.

For browses, this attribute applies only to combo-box browse columns.

**AUTO-DELETE attribute**

Specifies whether a dynamic buffer and temp-table object associated with a ProDataSet object is automatically deleted when the ProDataSet object is deleted. Dynamic buffer and temp-table objects associated with a ProDataSet object are deleted when the ProDataSet object is deleted, by default.

Set this attribute to FALSE to prevent a dynamic buffer and temp-table from being automatically deleted when the associated ProDataSet object is deleted. The default value is TRUE.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Buffer object handle

**AUTO-DELETE-XML attribute**

Determines whether the X-document object handle is deleted on a new web request. The default is YES.
AUTO-END-KEY attribute

Directs the AVM to apply the ENDKEY event to the current frame when a user chooses the button.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: WEB-CONTEXT system handle

If the AUTO-END-KEY attribute is TRUE, the AVM applies the ENDKEY event to the frame when the button is chosen. The default value is FALSE.

AUTO-ENDKEY is a synonym for the AUTO-END-KEY attribute.

AUTO-GO attribute

Directs the AVM to apply the GO event to the current frame when a user chooses the button.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BUTTON widget

If the AUTO-GO attribute is TRUE, the AVM applies the GO event to the frame when the button is chosen. The default value is FALSE.

AUTO-INDENT attribute

Specifies the text indentation behavior in the editor widget.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: EDITOR widget

If AUTO-INDENT is TRUE, each new line of text automatically indents to line up with the preceding line.
AUTO-RESIZE attribute
(Graphical interfaces only)

Tells the AVM how to resize a widget when the LABEL, FONT, or FORMAT attribute of the widget changes.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (column), BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

If the AUTO-RESIZE attribute is TRUE, the widget automatically resizes when the LABEL, FONT or FORMAT attributes of the widget change. If AUTO-RESIZE is FALSE, the widget retains its original size.

The default value for this attribute is TRUE for widgets that are not explicitly sized when they are defined, and FALSE for explicitly sized widgets.

When the AUTO-RESIZE attribute is set to TRUE, the AVM resizes button and toggle-box widgets with run-time changes to the LABEL attribute, and combo-box and fill-in field widgets with run-time changes to the FORMAT attribute.

This attribute resizes the following widgets with run-time changes to the FONT attribute:

- Browse columns
- Buttons
- Combo boxes
- Editors
- Fill-ins
- Radio sets
- Selection lists
- Sliders
- Texts
- Toggle boxes

For browse columns, if you set the browse column’s AUTO-RESIZE attribute to TRUE, the AVM resizes the browse column when a change occurs in the browse column’s font or in the font or text of the browse column’s label.

If the font of a browse column grows such that the height needs to be increased, the AVM increases the height of all cells in the browse column, which increases the row height of the browse (because all rows have the same height). This might affect the DOWN, ROW-HEIGHT-CHARS, and ROW-HEIGHT-PIXELS attributes of the browse column.
If the font of a browse column decreases, the AVM does not decrease the height of the rows, because the decrease might clip text in other columns.

**Note:** If the developer changes the size of the widget at run time by using the HEIGHT-CHARS, HEIGHT-PIXELS, WIDTH-CHARS, or WIDTH-PIXELS attribute, the AVM resets AUTO-RESIZE to FALSE.

### AUTO-RETURN attribute

Specifies the behavior that occurs when a user types the last allowable character in the widget.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (column), FILL-IN widget

The FORMAT attribute controls the number of characters that a user can enter in the widget. By default, if the user attempts to enter more characters than the number allowed in the widget, the AVM beeps and ignores characters. You can use the AUTO-RETURN attribute to alter this behavior only if the DATA-ENTRY-RETURN attribute of the SESSION handle is TRUE.

If DATA-ENTRY-RETURN and AUTO-RETURN are TRUE and a user types the last character in a field, a LEAVE event occurs and input focus moves to the next widget in the tab order. If the widget is the last widget in the tab order, a GO event occurs for the current frame. This behavior is the same as pressing RETURN or TAB in the field when the DATA-ENTRY-RETURN attribute is TRUE.

For browse columns, if AUTO-RETURN is TRUE, when the user enters the last allowable character in a browse-cell, the AVM behaves as if the user pressed the RETURN key.

### AUTO-SYNCHRONIZE attribute

Indicates whether the AVM automatically synchronizes a hierarchy of queries on a ProDataSet temp-table buffer.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Buffer object handle

Set to TRUE to synchronize the related buffers automatically. The default is FALSE.

When AUTO-SYNCHRONIZE is TRUE and a new row is placed in the buffer, the synchronize action occurs. The event handler is called when the buffer has a CREATE, DELETE, RELEASE, FIND, FOR-EACH, QUERY GET, or BUFFER-COPY run on it.

If the BUFFER-COPY is part of a FILL operation, a before-image operation (such as SAVE-ROW-CHANGES), or a deep-copy during parameter passing or COPY-TEMP-TABLE, then the synchronize action does not occur.
If you perform a manual FILL operation using BUFFER-COPY, you can prevent the query hierarchy from being synchronized unnecessarily by setting the AUTO-SYNCHRONIZE attribute to FALSE.

**AUTO-VALIDATE attribute**

Specifies when the AVM runs the validation for a browse column.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget

If TRUE, the AVM runs the validation for a browse column in the specified browser on LEAVE of the browse cell. If FALSE, the AVM runs the validation only when code for a browse or browse column specifically invokes the VALIDATE( ) method.

**AUTO-ZAP attribute**

Specifies what happens to the existing contents of the widget when the user types new information into the widget.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (cell), COMBO-BOX widget, FILL-IN widget

If AUTO-ZAP is TRUE, when the user begins typing in the field, the entire initial value is erased before the user’s text appears. If AUTO-ZAP is FALSE, text entered by the user is inserted into existing text at the current cursor position in the field.

You can set AUTO-ZAP only when the fill-in or cell has input focus (its handle is equal to the FOCUS handle). Otherwise, AUTO-ZAP is TRUE when the user tabs or back-tabs into the field, highlighting text in the field. (When the user selects all text in the field, the same effect occurs without setting the AUTO-ZAP attribute.) AUTO-ZAP is FALSE when the user enters the field with the mouse pointer, positioning the text cursor in the field.

For browses, this attribute applies only to fill-in and combo-box browse columns.

**AVAILABLE attribute**

Indicates whether a buffer contains a record.
AVAILABLE-FORMATS attribute

A comma-separated list of names that specify the formats available for the data currently stored in the clipboard.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** CLIPBOARD system handle

If there are no formats available, the attribute returns the Unknown value (?). The supported formats include:

- **PRO_TEXT** — Specifies the standard text format on your system (CF_TEXT in Windows)
- **PRO_MULTIPLE** — Specifies that the data in the clipboard contains tab or newline characters, and thus can be read as multiple items

For more information, see the reference entry for the CLIPBOARD system handle.

BACKGROUND attribute

Specifies the handle for the background iteration of the frame or dialog box.
BASE-ADE attribute

Sets the location of the ADE r-code directory. When set, the AVM adds the directory, followed by all the procedure libraries in the directory, to the PROPATH.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

You can also specify the ADE r-code location using the ADE R-code Location (-baseADE) startup parameter. For more information about the ADE R-code Location (-baseADE) startup parameter, see *OpenEdge Deployment: Startup Command and Parameter Reference*.

With the BASE-ADE attribute and the ADE r-code Location (-baseADE) startup parameter, you can have multiple versions of ADE r-code on the same machine and easily switch between them.

If -baseADE is not specified at startup, SESSION:BASE-ADE has the Unknown value (?) until it is set.

When SESSION:BASE-ADE is set, the AVM adds the directory, followed by all of the procedure libraries in the directory to PROPATH. If the directory or any of the procedure libraries are already on PROPATH, the AVM does not add them.

When SESSION:BASE-ADE is set, the AVM removes all PROPATH entries representing the current ADE r-code directory and procedure libraries before adding the new PROPATH entries. The AVM adds the new PROPATH entries at the location where it removed the previous entries. The AVM only removes PROPATH entries that it added. For example, if $DLC/gui/adecomm.pl is part of the PROPATH, it remains on the PROPATH after BASE-ADE is set to a directory other than $DLC/gui.

If BASE-ADE is set to an empty string, the AVM removes whatever it added to PROPATH.

The AVM does not remove the ADE r-code directory or any of the procedure libraries in that directory from PROPATH, even if the PROPATH statement does not contain them. These entries are part of the base PROPATH. If -baseADE or SESSION:BASE-ADE is used, the directory and procedure libraries that the AVM adds are part of the base PROPATH and remain part of the PROPATH even if the PROPATH statement does not contain them.

SESSION:BASE-ADE modifies PROPATH. If the old PROPATH contains a procedure library that is not in the new PROPATH, the AVM automatically closes the procedure library as long as there are no procedures from the library running.
BASIC-LOGGING attribute

Turns on QryInfo logging for an individual query.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Query object handle

ABL does not provide QryInfo logging for individual queries at logging level 2 (Basic), by default. You must use the BASIC-LOGGING attribute to turn on logging for an individual query when the logging level of the QryInfo log entry type is set to level 2 (Basic). If the logging level of the QryInfo log entry type is level 3 (Verbose) or higher, then ABL ignores any BASIC-LOGGING attribute setting and logs query information for all queries.

To set the logging level of the QryInfo log entry type, use the LOG-ENTRY-TYPES attribute or the Log Entry Types (-logentrytypes) startup parameter with the logging level option.

To turn on logging for an individual query when the logging level is set to 2 (Basic), you must set this attribute to **TRUE** before a query starts. For a dynamically opened query, this is before the QUERY-PREPARE() method. For a statically opened query, this is before the OPEN QUERY statement. If you set this attribute to **TRUE** after a query starts, ABL does not provide logging for that query.

To turn off logging for an individual query when the logging level is set to 2 (Basic), you must set this attribute to **FALSE**. If you set this attribute to **FALSE** before a query completes, ABL does not write query statistics to the log.

Whenever you turn on or turn off logging for an individual query using this attribute, ABL writes a log entry to the log file indicating the query ID, the query object handle, and the name of the query.

For more information about the Log Entry Types (-logentrytypes) startup parameter, see *OpenEdge Deployment: Startup Command and Parameter Reference*.

For more information about query logging, see *OpenEdge Development: Debugging and Troubleshooting*.

---

**BATCH-MODE attribute**

Indicates whether the current ABL session is running in batch mode or interactive mode.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** SESSION system handle

BATCH-MODE is **TRUE** when the current session is running in batch or background mode. A session runs in batch or background mode when it is:

- A client session started using the Batch (-b) startup parameter
- An AppServer agent session
• A WebSpeed agent session

**BATCH-SIZE attribute**

The maximum number of ProDataSet temp-table rows to retrieve in each FILL operation. The default value is zero (which retrieves all rows that satisfy the associated query).

**Note:** If you specify a batch size for a ProDataSet temp-table that is a child of a relation, the AVM restarts the BATCH-SIZE counter for each parent record (as opposed to once per temp-table).

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** Buffer object handle  

This attribute is not marshalled between the client and the AppServer (unlike the LAST-BATCH attribute).

**See also:** FILL( ) method, LAST-BATCH attribute

**BEFORE-BUFFER attribute**

Returns the handle to the default buffer of the before-image table that corresponds to the buffer of the after-image table currently associated with this buffer handle.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Buffer object handle  
**See also:** AFTER-BUFFER attribute

**BEFORE-ROWID attribute**

Returns the ROWID of the row in the before-image table that corresponds to the row in the after-image table currently associated with this buffer handle.

**Data type:** ROWID  
**Access:** Readable  
**Applies to:** Buffer object handle  

This attribute is set to the Unknown value (?) for row that have not changed.
BEFORE-TABLE attribute

Returns the handle of the before-image table that corresponds to the after-image table currently associated with this temp-table handle.

Data type: HANDLE
Access: Readable
Applies to: Temp-table object handle
See also: AFTER-TABLE attribute

BEGIN-EVENT-GROUP() method

Indicates (and records) the beginning of a group of related audit events in the current session. Audit event groups are used to group a series of related application and database audit events in one or more connected audit-enabled databases whose current audit policy has this audit event enabled.

This method returns a Base64 character string that specifies the universally unique identifier (UUID) of the primary index for all audit event records generated by this method for this audit event group. This UUID is recorded in all subsequent audit event records until you either end this audit event group or begin a different audit event group. The UUID is 22 characters in length (the two trailing Base64 pad characters are removed).

Return type: CHARACTER
Applies to: AUDIT-CONTROL system handle

Syntax

BEGIN-EVENT-GROUP( event-context [, event-detail [, audit-custom-detail ]])

event-context

A character expression that specifies the context for the audit event. The value of this expression cannot exceed 200 characters. You can also use this value as an alternate index for querying the audit event record.

If you specify the Unknown value (?), the AVM generates a run-time error.

event-detail

An optional character expression that specifies additional audit detail. The value of this expression cannot exceed 10,000 characters.

audit-custom-detail

An optional character expression that specifies additional user detail. The value of this expression cannot exceed 10,000 characters.
The UUID is saved as the EVENT-GROUP-ID attribute value for each connected audit-enabled database.

There can be only one active event group per session at any one point in time. To set a different event group for the session, you can:

- Call the END-EVENT-GROUP( ) method, to end the current event group, and then call the BEGIN-EVENT-GROUP( ) method to begin the new event group.
- Call the BEGIN-EVENT-GROUP( ) method to begin the new event group. If there is an existing event group in effect, the AVM ends the existing event group before beginning the new event group.

Calling this method generates an audit event, and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.

The following code fragment illustrates how to use the BEGIN-EVENT-GROUP( ) method:

```
DEFINE VARIABLE name AS CHARACTER NO-UNDO.
DEFINE VARIABLE ctx-id AS CHARACTER NO-UNDO.
DEFINE VARIABLE grp-id AS CHARACTER NO-UNDO.

... 
grp-id = AUDIT-CONTROL:BEGIN-EVENT-GROUP
    ("Payroll app", "tax calculations", name).
ctx-id = AUDIT-CONTROL:SET-APPL-CONTEXT
    ("Payroll app", "federal tax calculation", name).
... 
AUDIT-CONTROL:LOG-AUDIT-EVENT(34122, "payroll.fed.tax.nh").
... 
ctx-id = AUDIT-CONTROL:SET-APPL-CONTEXT
    ("Payroll app", "fica calculation", name).
... 
AUDIT-CONTROL:LOG-AUDIT-EVENT(34123, "payroll.fed.tax.ma").
... 
AUDIT-CONTROL:CLEAR-APPL-CONTEXT.
AUDIT-CONTROL:END-EVENT-GROUP.
```

See also: END-EVENT-GROUP( ) method, EVENT-GROUP-ID attribute

BGCOLOR attribute
(Graphical interfaces only)

Specifies the color number for the background color of the widget.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget (browse, column, and cell), COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

The color number represents an entry in the color table maintained by the COLOR-TABLE handle.
For a rectangle, if the FILLED attribute is TRUE, BGCOLOR specifies the color of the region inside the border of the rectangle.

For a browse cell, BGCOLOR specifies the color of a specific cell in the view port. You can set this color only as the cell appears in the view port during a ROW-DISPLAY event.

You cannot set this attribute for a BUTTON widget.

Setting the BGCOLOR attribute for any of the following field-level widgets within a dialog-box or frame overrides any INHERIT-BGCOLOR attribute or option settings: BROWSE, COMBO-BOX (all types), EDITOR, FILL-IN (NATIVE and Enabled), and SELECTION-LIST.

See also: FGCOLOR attribute, Frame phrase, INHERIT-BGCOLOR attribute

**BLANK attribute**

Suppresses the display of sensitive data in a field.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** FILL-IN widget, TEXT widget

If the BLANK attribute is TRUE, any current value or characters typed in the fill-in are not echoed to the screen. The default value for this attribute is FALSE.

**BLOCK-ITERATION-DISPLAY attribute**

Specifies if the Frame phrase of the frame contains the NO-HIDE option or if the frame has multiple iterations (is a DOWN frame).

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** FRAME widget

The BLOCK-ITERATION-DISPLAY attribute returns TRUE if the NO-HIDE option is specified in a frame phrase for the frame or the frame has multiple iterations.

**BORDER-BOTTOM-CHARS attribute**

The thickness, in character units, of the border at the bottom of the frame or dialog box.

**Data type:** DECIMAL

**Access:** Readable

**Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.
**BORDER-BOTTOM-PIXELS attribute**

The thickness, in pixels, of the border at the bottom of the frame or dialog box.

- **Data type:** INTEGER
- **Access:** Readable
- **Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.

---

**BORDER-LEFT-CHARS attribute**

The thickness, in character units, of the border at the left side of the frame or dialog box.

- **Data type:** DECIMAL
- **Access:** Readable
- **Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.

---

**BORDER-LEFT-PIXELS attribute**

The thickness, in pixels, of the border at the left side of the frame or dialog box.

- **Data type:** INTEGER
- **Access:** Readable
- **Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.

---

**BORDER-RIGHT-CHARS attribute**

The thickness, in character units, of the border at the right side of the frame or dialog box.

- **Data type:** DECIMAL
- **Access:** Readable
- **Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.

---

**BORDER-RIGHT-PIXELS attribute**

The thickness, in pixels, of the border at the right side of the frame or dialog box.
**BORDER-TOP-CHARS attribute**

The thickness, in character units, of the border at the top of the frame or dialog box.

- **Data type:** DECIMAL
- **Access:** Readable
- **Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.

**BORDER-TOP-PIXELS attribute**

The thickness, in pixels, of the border at the top of the frame or dialog box.

- **Data type:** INTEGER
- **Access:** Readable
- **Applies to:** DIALOG-BOX widget, FRAME widget

This attribute returns zero if the BOX attribute for the widget is FALSE.

**BOX attribute**

Indicates whether the widget has a graphical border around it.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** EDITOR widget, FRAME widget

If the BOX attribute is FALSE, the widget does not have a border. You can set this attribute only before the widget is realized.

For editors, BOX has no effect on the size of the editor.

**BOX-SELECTABLE attribute**  
*(Graphical interfaces only)*

Indicates whether box-selection direct manipulation events for the frame or dialog box are enabled or disabled.
BUFFER-CHARS attribute

Data type: LOGICAL
Access: Readable/Writeable
 Applies to: DIALOG-BOX widget, FRAME widget

If the BOX-SELECTABLE attribute is TRUE, then the START-BOX-SELECTION and END-BOX-SELECTION direct manipulation events are enabled for the frame or dialog box. This allows the user to select one or more widgets in the frame or dialog box by stretching a select box around the widgets. The SELECTABLE attribute must be TRUE for at least one widget in the frame or dialog box for this attribute to be effective. Otherwise, the user can stretch a select box, but without any effect on the widgets in the frame or dialog box.

BUFFER-CHARS attribute
(Character interfaces only)

The number of characters a user can enter on each line of the editor.

Data type: INTEGER
Access: Readable/Writeable
 Applies to: EDITOR widget

You can set this attribute only before the editor widget is realized. The value must be an integer expression that is equal to or greater than the value specified by the WIDTH-CHARS or INNER-CHARS attributes. If greater, horizontal scrolling is enabled.

When the last character is typed on a line in the editor, the text input cursor automatically wraps to the next line. This attribute can also set the word wrap margin for the WORD-WRAP attribute. For more information, see the WORD-WRAP attribute reference entry.

BUFFER-COMPARE( ) method

This method does a rough compare of any common fields, determined by name, data type, and extent-matching, between the source buffer and the target buffer. The resulting logical value is either TRUE or FALSE as a whole. A single field that does not compare causes the entire buffer to return FALSE. If there are fields in one buffer that do not exist in the other, they are ignored.

Return type: LOGICAL
 Applies to: Buffer object handle

Syntax

\[
\text{BUFFER-COMPARE}( \text{source-buffer-handle} [ , \text{mode-exp} [ , \text{except-list} [ , \text{pairs-list} [ , \text{no-lobs} ] ] ] ] )
\]

source-buffer-handle

An expression that evaluates to a buffer handle.
**mode-exp**

If mode-exp is given, it must evaluate to either “binary” or “case-sensitive” to provide that type of comparison.

**except-list**

A character expression that evaluates to a comma-separated list of field names to be excluded from the compare.

**pairs-list**

A character expression that evaluates to a comma-separated list of field-name pairs to be compared.

You can specify an array element as one or both of the fields. This lets you compare a field or array element in one buffer to a field or array element in the other buffer, when the two fields do not have the same name. The order within each field-name pair does not matter; each pair must contain one field name from the source and one field name from the target.

You can also compare one entire array to another by specifying its name without a subscript.

**no-lobs**

A logical expression indicating whether to ignore BLOB and CLOB fields in the compare. If TRUE, BLOB and CLOB fields are ignored during the compare. If FALSE, BLOB and CLOB fields are compared along with the other fields. The default value is FALSE (that is, BLOB and CLOB fields are included in the compare).

**Note:** You cannot use the BUFFER-COMPARE( ) method to compare records that contain CLOB fields, unless one or both of the corresponding fields contain the Unknown value (?); the AVM generates a run-time error. However, you can convert CLOB fields to LONGCHAR values and use the EQ, GE, GT, LE, LT, and NE comparison operators, or the COMPARE function, to compare the LONGCHAR values.

If you want to compare BLOB fields only, you can set this option to FALSE and use the except-list option to exclude CLOB fields from the compare.

**Caution:** When using this option, you get no warning if a LOB field has changed. This can lead to inappropriate results. Therefore, before using this option, you must understand the nature of your data and be sure that logic using this option will not result in inconsistent or out-of-date data in the database.

When comparing buffers in a ProDataSet object, the AVM checks as to whether the BUFFER-COMPARE( ) method satisfies the following two requirements:

- The compare is between a buffer on a Data-source object table and the corresponding ProDataSet temp-table buffer. This means the operation can use any buffer for the data source database table, but only the default buffer for the ProDataSet temp-table.

- There are no except-list or pairs-list arguments for the BUFFER-COMPARE( ) method.
If these two requirements are satisfied, the BUFFER-COMPARE( ) method identifies the fields
to compare based on the pairs-list argument specified in the ATTACH-DATA-SOURCE( )
method for the Data-source object, if any, along with either the except-list or include-list
arguments, if any. Because the ATTACH-DATA-SOURCE( ) method already allows you to
define a field mapping between a Data-source object buffer and a ProDataSet temp-table buffer,
as well as a list of fields to include or exclude from the operation, you do not need to specify
these in the BUFFER-COMPARE( ) method.

When comparing records that contain BLOB fields, the AVM performs a binary comparison on
the BLOB data associated with the source and target records.

Use the no-lobs option with the BUFFER-COMPARE( ) method to ignore large object data
when comparing records that contain BLOB or CLOB fields. You can also use the except-list
option to exclude BLOB and CLOB fields from the compare.

The following example fragment performs a binary compare of all fields in the buffers, except
for the two specified fields:

```
BUFFER-COMPARE(bh2, "binary", "cust-sales-rep, SalesRep").
```

**BUFFER-COPY( ) method**

This method copies any common fields, determined by name, data type, and extent-matching,
from the source buffer to the receiving buffer. If there are fields in one buffer that do not exist
in the other, they are ignored. This method is used to accommodate temp-tables of joins.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

**Syntax**

```
BUFFER-COPY( source-buffer-handle
```

*source-buffer-handle*

An expression that evaluates to the source buffer handle.

*except-list*

A character expression that evaluates to a comma-separated list of field names to be
excluded from the copy.

*pairs-list*

A character expression that evaluates to a comma-separated list of field-name pairs to be
copied.

You can also specify an array element as one or both of the fields. This lets you copy a
field or array element from one buffer to a field or array element in the other buffer, when
the two fields do not have the same name. The order within each field-name pair does not
matter; each pair must contain one field name from the source and one field name from the target.

You can also copy one entire array to another by specifying its name without a subscript.

**no-lobs**

A logical expression indicating whether to ignore BLOB and CLOB fields in the copy. If TRUE, BLOB and CLOB fields are ignored during the copy. If FALSE, BLOB and CLOB fields are copied along with the other fields. The default value is FALSE (that is, BLOB and CLOB fields are included in the copy).

**Caution:** Using this option can create the potential for errors in your data and lead to inappropriate results. Therefore, before using this option, you must understand the nature of your data and be sure that logic using this option will not result in inconsistent or out-of-date data in the database.

When copying buffers in a ProDataSet object, the AVM checks as to whether the BUFFER-COPY( ) method satisfies the following two requirements:

- The copy is between a buffer on a Data-source object table and the corresponding ProDataSet temp-table buffer. This means the operation can use any buffer for the data source database table, but only the default buffer for the ProDataSet temp-table.

- There are no except-list or pairs-list arguments for the BUFFER-COPY( ) method.

If these two requirements are satisfied, the BUFFER-COPY( ) method identifies the fields to copy based on the pairs-list argument specified in the ATTACH-DATA-SOURCE( ) method for the Data-source object, if any, along with either the except-list or include-list arguments, if any. Because the ATTACH-DATA-SOURCE( ) method already allows you to define a field mapping between a Data-source object buffer and a ProDataSet temp-table buffer, as well as a list of fields to include or exclude from the operation, you do not need to specify these in the BUFFER-COPY( ) method.

When copying records that contain a BLOB or CLOB field, the AVM copies the object data associated with the source record to the target record. If the BLOB or CLOB field in the source record contains the Unknown value (?), the AVM stores the Unknown value (?) in the BLOB or CLOB field of the target record. If the target record already has object data associated with it, the AVM deletes that object data before copying the new object data.

Use the no-lobs option with the BUFFER-COPY( ) method to ignore large object data when copying records that contain BLOB or CLOB fields. More specifically:

- When you copy a source record to a new target record, the AVM sets the value of the BLOB or CLOB field in the target record to the Unknown value (?).

- When you copy a source record to an existing target record, the AVM does not change the value of the BLOB or CLOB field in the existing target record.

You can also use the except-list option to exclude BLOB and CLOB fields from the copy.

The following example fragment copies the Customer table to the buffer, bh, except that Customer.SalesRep is copied to a field called cust-sales-rep in the buffer:
BUFFER-CREATE( ) method

Creates a record, sets fields to their default values, and moves a copy of the record into the buffer.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle

**Syntax**

```
BUFFER-CREATE()
```

**Note:** The BUFFER-CREATE method corresponds to the CREATE statement.

BUFFER-DELETE( ) method

Deletes a record from the record buffer and from the database.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle

**Syntax**

```
BUFFER-DELETE()
```

The BUFFER-DELETE method corresponds to the DELETE statement.

If the table has delete validation—that is, if the table specifies an expression that must be true before the record is deleted—the record is not deleted, because the validation expression, normally applied at compile time, cannot be applied fully at run time.

BUFFER-FIELD attribute

The handle of the browse column’s buffer-field.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** BROWSE widget (column)

If the browse column does not have a corresponding buffer field, the Unknown value (?) will be returned.

```
bh:BUFFER-COPY(BUFFER Customer:HANDLE, ?, "cust-sales-rep,SalesRep").
```
**BUFFER-FIELD( ) method**

Returns a handle to a particular field in the buffer.

**Return type:** HANDLE  
**Applies to:** Buffer object handle

**Syntax**

```
BUFFER-FIELD ( field-number | field-name )
```

*field-number*

An integer expression representing the sequence number of the field in the buffer.

*field-name*

A CHARACTER string expression representing the name of the field in the buffer.

---

**BUFFER-HANDLE attribute**

The handle of the buffer object to which the buffer-field belongs.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Buffer-field object handle

---

**BUFFER-LINES attribute**  
*(Character interfaces only)*

The number of lines a user can enter into the editor.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** EDITOR widget

You can set this attribute only before the editor widget is realized. The value must be an integer expression that is equal to or greater than the value specified by the HEIGHT-CHARS or INNER-LINES attributes. If equal, vertical scrolling is disabled.

By default, the AVM does not limit the number of enterable lines (although system limits may apply).

---

**BUFFER-NAME attribute**

The name of the buffer object to which the buffer-field object belongs.
**BUFFER-RELEASE( ) method**

Releases a record from a buffer object. The BUFFER-RELEASE method corresponds to the RELEASE statement.

**Note:** To delete the buffer object, use the DELETE OBJECT statement.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

**Syntax**

```plaintext
BUFFER-RELEASE ( )
```

If a record has been modified, this method causes a WRITE event and executes all related WRITE triggers.

If successful, this method returns TRUE. Otherwise, it returns FALSE. If the validation fails on a newly-created record, this method returns FALSE and raises the ERROR condition.

**BUFFER-VALIDATE( ) method**

Verifies that a record in a buffer object complies with mandatory field and unique index definitions. The BUFFER-VALIDATE( ) method corresponds to the VALIDATE statement.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

**Syntax**

```plaintext
BUFFER-VALIDATE ( )
```

If a field or table has been modified, this method causes a WRITE event and executes all related WRITE triggers.

If successful, this method returns TRUE. Otherwise, it returns FALSE. If the validation fails on a newly-created record, this method returns FALSE and raises the ERROR condition.

The record is not released and the lock status remains the same as before the BUFFER-VALIDATE( ).
**BUFFER-VALUE( ) method**

The current value of a buffer-field object. If you modify the BUFFER-VALUE( ) method, the AVM sets the buffer-field object to the new value.

- **Data type:** The data type of the corresponding buffer-field
- **Access:** Readable/Writeable
- **Applies to:** Buffer-field object handle

**Syntax**

```
BUFFER-VALUE( [ i ] )
```

- `i`  
  An integer expression representing a subscript, for fields that have extents.

The syntax for retrieving the value of a buffer-field object using a dynamic reference to a table field in a dynamic ProDataSet, temp-table, query, or buffer object can be awkward, especially when you know the table and field names at compile time. ABL provides a simpler way to express the same syntax, only in a short-hand form. For example, following is the typical syntax for referring to the CustNum buffer field in the Customer table through a ProDataSet handle:

```
hdSet:GET-BUFFER-HANDLE("ttcust"):BUFFER-FIELD("CustNum"):BUFFER-VALUE( )
```

Following is the short-hand form of the same syntax:

```
hDSet::ttcust::CustNum
```

**Note:** Progress Software Corporation recommends that you do not set the call object's CALL-TYPE attribute to SET-ATTR-CALL-TYPE to set a BUFFER-FIELD object's BUFFER-VALUE ( ) method return value, since there in no way to run triggers for the target field.

**See also:** LITERAL-QUESTION attribute

---

**BYTES-READ attribute**

Returns the number of bytes read from the socket via the last READ( ) method. If the last READ( ) method failed, this attribute will return 0.
BYTES-WRITTEN attribute

Returns the number of bytes written to the socket via the last WRITE( ) method. If the last WRITE( ) method failed, this attribute will return 0.

Data type: INTEGER
Access: Readable
Applies to: Socket object handle

CACHE attribute

Specifies how many records a NO-LOCK query should hold in memory.

Data type: INTEGER
Access: Readable/Writeable
Applies to: Query object handle
Note: The CACHE attribute corresponds to the CACHE option of the DEFINE QUERY statement.

CALL-NAME attribute

The name of one of the following:

- An external procedure, internal procedure, or user-defined function you want to invoke dynamically
- A Windows DLL routine or Unix shared library routine you want to invoke dynamically
- An attribute you want to get or set dynamically
- A method you want to run dynamically

Data type: CHARACTER
Access: Readable/Writable
Applies to: Call object handle

Syntax

CALL-NAME [ = char-expression ]
**CALL-TYPE attribute**

A CHARACTER expression indicating the name of the procedure, user-defined function, attribute, method, or shared library routine. The default is the Unknown value (?).

If `char-expression` is a procedure, the rules for finding the procedure are the same as those of the RUN statement, including the treatment of SUPER. However, the actual instance of the file, procedure name, or attribute is not determined until the dynamic invoke is executed.

If `char-expression` is a user-defined function, an attribute, or a method, the rules for finding the function or attribute are the same as those for finding a function or attribute invoked statically.

If `char-expression` is a shared library routine, at least the following attributes must be set:

- CALL-NAME or ORDINAL
- CALL-TYPE
- LIBRARY
- RETURN-VALUE-DLL-TYPE

If `char-expression` is a shared library routine and LIBRARY specifies a full path name, the AVM searches only that path for the shared library. Otherwise, the AVM first determines if the shared library is loaded in memory. If it is not loaded in memory, the AVM looks for the shared library in the current working directory. If the shared library cannot be found at this point:

- On Windows the AVM uses the standard Windows search algorithm to find the DLL, the same algorithm used to find Windows executable (.exe) files
- On UNIX the AVM continues searching for the shared library using the ABL PROPATH

Using the call object handle, there are two alternate methods for invoking a DLL routine—either by specifying the routine’s name with the CALL-NAME attribute or by specifying the routine’s position in the DLL with the ORDINAL attribute. You can specify an ORDINAL value or a CALL-NAME value, but not both. Specifying an ORDINAL value and setting CALL-NAME at the same time causes the AVM to raise error at run time.

**See also**  
ORDINAL attribute

---

**CALL-TYPE attribute**

The type of call, which must be the dynamic version of one of the following:

- Invoking an external or internal procedure
- Invoking a user-defined function
- Invoking a Windows DLL routine or a Unix shared library routine
- Getting an attribute
- Setting an attribute
CANCEL-BREAK( ) method

- Invoking a method

**Data type:** INTEGER

**Access:** Readable/Writable

**Applies to:** Call object handle

You can use a keyword constant or an integer. Table 68 lists the keyword constants and integer values you can use.

**Table 68: Keyword constants for the CALL-TYPE attribute**

<table>
<thead>
<tr>
<th>Keyword constant</th>
<th>Integer value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCEDURE-CALL-TYPE</td>
<td>1</td>
</tr>
<tr>
<td>FUNCTION-CALL-TYPE</td>
<td>2</td>
</tr>
<tr>
<td>GET-ATTR-CALL-TYPE</td>
<td>3</td>
</tr>
<tr>
<td>SET-ATTR-CALL-TYPE</td>
<td>4</td>
</tr>
<tr>
<td>DLL-CALL-TYPE</td>
<td>5</td>
</tr>
</tbody>
</table>

The default is PROCEDURE-CALL-TYPE.

To get the value of an attribute or to invoke a method, set CALL-TYPE to GET-ATTR-CALL-TYPE.

In this example, the SESSION:NUMERIC-FORMAT attribute is assigned, indicated by the CALL-TYPE value of SET-ATTR-CALL-TYPE:

```c
/* Set SESSION:NUMERIC-FORMAT to "european" */
ASSIGN
hCall:IN-HANDLE    = "session"
hCall:CALL-TYPE    = SET-ATTR-CALL-TYPE
hCall:CALL-NAME    = "numeric-format"
hCall:NUM-PARAMETERS = 1.

hCall:SET-PARAMETER(1, "CHARACTER", "INPUT", "european").
hCall:INVOKE.
```

**Note:** PSC recommends that you do not set the call object’s CALL-TYPE attribute to SET-ATTR-CALL-TYPE to set a BUFFER-FIELD object’s BUFFER-VALUE attribute, since there is no way to run triggers for the target field.

---

CANCEL-BREAK( ) method

Cancels a breakpoint from a debugging session.
CANCEL-BREAK attribute

Return type: LOGICAL
Applies to: DEBUGGER system handle

Syntax

```
CANCEL-BREAK( [ procedure [ , line-number ] ] )
```

**procedure**

A character expression that specifies the name of the procedure for which you want to cancel a breakpoint. The specified procedure does not have to exist at the time the breakpoint is cancelled. If you do not specify *procedure*, the method cancels any breakpoint set on the line immediately following the current line. (This is different from the SET-BREAK( ) method, which sets a breakpoint on the next executable line.)

**line-number**

An integer expression that specifies the line number in *procedure* (based at line 1 of the debug listing) where you want to cancel the breakpoint. A positive integer greater than or equal to 1 represents a line number in the specified *procedure* file. Zero (0) or a negative integer value represents the first executable line of the main procedure block in the specified *procedure* file. If you do not specify *line-number*, the method cancels the breakpoint at the first executable line of *procedure* file.

If you invoke DEBUGGER:CANCEL-BREAK( *procedure*, *line-number* ) on the same line that is specified by *procedure* and *line-number*, the existing breakpoint on the specified line occurs the first time it is executed. The breakpoint is cancelled only on the second and succeeding executions of the line.

To use this method, you must have the Application Debugger installed in your OpenEdge environment.

CANCEL-BUTTON attribute

A button widget in the frame or dialog box to receive the CHOOSE event when a user cancels the current frame or dialog box by pressing the ESC key.

**Data type:** HANDLE
**Access:** Readable/Writeable
**Applies to:** DIALOG-BOX widget, FRAME widget

Any other action normally associated with the ESC key is not performed. The ESC key is any key associated with the ESC key label.

The CANCEL-BUTTON attribute for frames is not supported in character mode.

If the user presses ESCAPE in a frame that has no such cancel button and the frame is part of a frame family, the AVM applies the CHOOSE event to the first cancel button it finds within the frame family in random order.
CANCEL-REQUESTS( ) method

For a state-reset, state-aware, or stateless AppServer, this method raises a STOP condition in the context of the currently running asynchronous request and purges the send queue of any asynchronous requests that have not been executed on the specified AppServer.

For a state-free AppServer, this method raises a STOP condition for all currently running asynchronous requests, and purges the send queue of any asynchronous requests that have not been executed on the specified AppServer.

For Web services, this method terminates the connection to all currently running asynchronous requests and purges the send queue of all asynchronous requests that have not been executed on the specified Web service.

**Return type:** LOGICAL

**Applies to:** Server object handle

**Syntax**

```
CANCEL-REQUESTS()
```

After executing this method, at the next I/O-blocking state (or on executing the PROCESS EVENTS statement) event procedures execute for the following asynchronous requests:

- All requests that were complete when this method executed but whose event procedures have not been run.
- All currently running requests that were stopped in response to this method
- All requests that were purged from the send queue, and never run

This method returns FALSE when the server handle is not in the connected state. (See the CONNECTED( ) method). Otherwise, this method returns TRUE.

**See also:** CANCEL-REQUESTS-AFTER( ) method

---

CANCEL-REQUESTS-AFTER( ) method

Calls the CANCEL-REQUESTS-AFTER( ) method on the server object after the specified number of seconds have elapsed. When CANCEL-REQUESTS-AFTER( ) is called, all requests currently running or queued to run on the server object are cancelled, regardless of when they were started.

If the method is called on a server object that already has a timer running, the timer is restarted with the new time interval, measured from that moment.

If the method is called with a parameter whose value is less than or equal to zero, then the timer on that server object is stopped.
**CANCELLED attribute**

**Return type:** LOGICAL

**Applies to:** Server object handle

**Syntax**

```plaintext
CANCEL-REQUESTS-AFTER(seconds)
```

**seconds**

This required integer parameter specifies the number of seconds before the CANCEL-REQUESTS-AFTER() method is called on the server object.

The method returns TRUE unless an error occurs while setting the timer. In that case, the method returns FALSE, and the timeout is not set.

**Example**

The following simple example uses the CANCEL-REQUESTS-AFTER() method:

```plaintext
DEFINE VARIABLE hSrv as HANDLE.
DEFINE VARIABLE bool as BOOLEAN.

CREATE SERVER hSrv.
hSrv:CONNECT("-URL AppServerDC://hostName/svc").
bool = hSrv:CANCEL-REQUESTS-AFTER(30).
RUN foo.p ON SERVER hSrv ASYNCHRONOUS ("Hello World").
WAIT-FOR WINDOW-CLOSE OF CURRENT-WINDOW.
```

**Notes**

Calling this method on a server object has no immediate effect on any asynchronous requests that are currently running (or queued to run) on that server object. Moreover, the length of time these requests have already been running prior to the call does not affect the timer.

The method can be called before or after the asynchronous requests are run. Any asynchronous requests that are run after the method is called must complete before the timer expires. The time available to complete such a request depends on when it was executed, with respect to the CANCEL-REQUESTS-AFTER() method call.

The timer has no effect on requests run synchronously during the time interval. Synchronous requests are not cancelled, even if they run longer than the specified timeout.

Manually calling the CANCEL-REQUESTS-AFTER() method in the application program during the timeout period has no effect on the timer.

**See also:** CANCEL-REQUESTS() method

---

**CANCELLED attribute**

Indicates if the asynchronous request was cancelled using either the CANCEL-REQUESTS() method or the DISCONNECT() method on the associated server handle.
**CAN-CREATE attribute**

Indicates whether the ABL user has permission to insert into the database the record associated with a buffer.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Buffer object handle

For information about checking permissions at compile time and run time, see *OpenEdge Deployment: Managing ABL Applications.*

**CAN-DELETE attribute**

Indicates whether the ABL user has permission to delete from the database the record associated with a buffer.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Buffer object handle

For information about checking permissions at compile time and run time, see *OpenEdge Deployment: Managing ABL Applications.*

**CAN-READ attribute**

Indicates whether the ABL user has permission to read the record associated with a buffer or buffer-field.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Buffer object handle, Buffer-field object handle

For information about checking permissions at compile time and run time, see *OpenEdge Deployment: Managing ABL Applications.*
CAN-WRITE attribute

Indicates whether the ABL user has permission to modify the record associated with a buffer or buffer-field.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** Buffer object handle, Buffer-field object handle

For information about checking permissions at compile time and run time, see *OpenEdge Deployment: Managing ABL Applications*.

CAREFUL-PAINT attribute

Indicates whether overlapping widgets in a 3D frame will refresh (repaint) carefully but more slowly (TRUE), or quickly, but possibly not as carefully (FALSE).

The CarefulPaint setting in the Startup section of the progress.ini file is used to determine the initial setting of the CAREFUL-PAINT attribute. The default value is TRUE.

You can set this frame attribute at any time.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** FRAME widget

CASE-SENSITIVE attribute

Indicates whether a buffer-field is case-sensitive.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** Buffer-field object handle

CENTERED attribute

Indicates whether the AVM automatically centers the frame in a window.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** FRAME widget

The default value for this attribute is FALSE. When you set this attribute from FALSE to TRUE, the values of the COLUMN, ROW, X, and Y attributes for the frame change to reflect the new location of the frame. Setting the CENTERED attribute from TRUE to FALSE has no meaning and results in an error message.
CHARSET attribute

The current setting of the Character Set (-charset) parameter.

Data type: CHARACTER
Access: Readable
Applies to: SESSION system handle

The CHARSET attribute returns a value that specifies the character set used for ABL data, which is either "iso8859-1" or "undefined". The value is set by the Character Set (-charset) parameter.

This attribute is obsolete. See the CPINTERNAL attribute.

CHECKED attribute

The display state for a toggle box or a toggle-box menu item.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: MENU-ITEM widget, TOGGLE-BOX widget

When this attribute is TRUE, the center of the toggle is filled to represent the “on” state of the value associated with the widget. Setting this attribute to FALSE removes the fill from the center of the toggle to represent the “off” state for the value associated with the widget.

CHILD-BUFFER attribute

Returns the buffer handle of the child member of the data-relation object.

Data type: HANDLE
Access: Readable
Applies to: Data-relation object handle

CHILD-NUM attribute

Returns the relative number assigned to this XML node among its siblings. XML nodes that have the same parent are called siblings, and are numbered from 1 to the number of siblings.

Data type: INTEGER
Access: Readable
Applies to: X-noderef object handle

The Unknown value (?) is returned if the node reference does not refer to an element node, or if the node is an XML document node.
The following example demonstrates the use of the CHILD-NUM attribute:

```
my-index = hNoderef:CHILD-NUM.
```

---

**CLASS-TYPE attribute**

Returns the class type of the most recently compiled class definition (.cls) file. If the most recently compiled file was not a class definition file, this attribute returns the empty string ("").

- **Data type:** CHARACTER
- **Access:** Readable
- **Applies to:** COMPILER system handle

---

**CLEAR() method (Handle)**

This method performs the following actions:

- Resets each attribute of a call object to its default value, which lets you reuse a call object.
- Removes all elements from a dynamic ProDataSet object including buffers and relations. That is, it restores the state of the dynamic ProDataSet object to what it was immediately after the CREATE DATASET statement.
- Initializes the internal state of the Application Debugger.
- Clears temp-table definitions and removes temp-table data.

- **Return type:** LOGICAL
- **Applies to:** Call object handle, ProDataSet object handle, DEBUGGER system handle, Temp-table object handle

**Syntax**

```
CLEAR ( )
```

For the Application Debugger system handle:

- This method has no visible effect on the Debugger window.
- If the Debugger is initialized, this method returns TRUE. Otherwise, it returns FALSE with no effect.

**Note:** To use this method with the DEBUGGER system handle, you must have the Application Debugger installed in your OpenEdge environment.

For more information on using this method for the Debugger, see the reference entry for the DEBUGGER system handle and *OpenEdge Development: Debugging and Troubleshooting*.
For the call object handle, this method resets each attribute of a call object to its default value, which lets you reuse a call object.

**Note:** To reset just the parameters, set the NUM-PARAMETERS attribute to zero.

For the temp-table object handle:

- This method empties the temp-table and removes all its definitional data (field and index definitions and pending saved data). This puts the temp-table object into the CLEAR state, as opposed to the UNPREPARED or PREPARED state.
- Calling any method after this one changes the state to UNPREPARED.

---

**CLEAR-APPL-CONTEXT( ) method**

Clears the application context for the current session.

**Return type:** LOGICAL

**Applies to:** AUDIT-CONTROL system handle

**Syntax**

```
CLEAR-APPL-CONTEXT( )
```

After calling this method, the APPL-CONTEXT-ID attribute is cleared for all connected audit-enabled databases and is no longer recorded in audit event records for this application context.

There can be only one active application context per session at any one point in time. To set a different application context for the session, you can:

- Call the CLEAR-APPL-CONTEXT( ) method, to clear the current application context, and then call the SET-APPL-CONTEXT( ) method with the new application context.
- Call the SET-APPL-CONTEXT( ) method with the new application context. If there is an existing application context in effect, the AVM clears the existing application context before setting the new application context.

Calling this method does not generate an audit event or an audit record.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

**See also:** APPL-CONTEXT-ID attribute, SET-APPL-CONTEXT( ) method

---

**CLEAR-LOG( ) method**

Clears all messages existing in the current client log file and leaves the file open for writing.
**CLEAR-SELECTION( ) method**

Removes the highlight from the currently selected text.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget (column), COMBO-BOX widget, EDITOR widget, FILL-IN widget

**Syntax**

```
CLEAR-SELECTION( )
```

If the highlight is removed, the method returns TRUE. Otherwise, it returns FALSE.

For browses, this method applies only to fill-in and combo-box browse columns.

---

**CLEAR-LOG( ) method**

This method is valid only for DataServers, interactive clients, and batch clients. WebSpeed agents and AppServers write a message to the server log file indicating that it is invalid to use the CLEAR-LOG( ) method to clear a WebSpeed or AppServer server log file. In this case, the method returns FALSE.

WebSpeed agents and AppServers silently ignore the Client Logging (-clientlog) startup parameter. The broker handles the clearing of the WebSpeed and AppServer server logs, through the srvrLogAppend property in the ubroker.properties file.

**Return type:** LOGICAL  
**Applies to:** DSLOG-MANAGER system handle, LOG-MANAGER system handle

**Syntax**

```
CLEAR-LOG( )
```

If the CLEAR-LOG( ) method successfully clears the open log file, it returns TRUE.

If the CLEAR-LOG( ) method fails, it returns FALSE and displays a warning message indicating the reason for the failure.

If there is no client log file, the CLEAR-LOG( ) method returns FALSE and displays a warning message that the operation is not valid when there is no log file.

If you specified a log file threshold with either the Log Threshold (-logthreshold) startup parameter or the srvrLogThreshold property in the ubroker.properties file, the CLEAR-LOG( ) method deletes any existing log files that match the name of the LOGFILE-NAME attribute, the Client Logging (-clientlog) startup parameter, or the DataServer Logging (-dslog) startup parameter. The method then re-creates and opens the first log file in the sequence and changes the LOGFILE-NAME attribute to reflect this.

---

**CLEAR-SORT-ARROWS( ) method**

Clears sort-arrow indicators for all columns in a browse.
CLIENT-CONNECTION-ID attribute

For a session-managed application, this attribute returns the connection ID for the physical AppServer connection associated with this server handle.

For a session-free application, the connection is a binding to an application service that relies on a pool of AppServer connections to service all requests from the client. This attribute returns the connection ID for the first physical AppServer connection associated with the server handle.

For Web services, this attribute returns the empty string.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** Server object handle

This value is assigned by the AppServer broker when an AppServer accepts a connection request from a client application. The AppServer broker and all AppServer agents use the connection ID as an identifier when they log any information associated with the connection.

The same connection ID is available to an ABL client application using the CLIENT-CONNECTION-ID attribute and to the AppServer agent servicing the client on the same connection using the SERVER-CONNECTION-ID attribute on the SESSION handle.

The value of the connection ID is guaranteed to be globally unique for all time within a single computer network. Connection IDs can be compared to each other strictly for equality, but other types of comparisons are irrelevant.

For a client, the connection ID of the associated AppServer connection remains the same until the client disconnects from the AppServer. If the client reconnects to the same AppServer, the connection ID of the new connection (and thus the value of the CLIENT-CONNECTION-ID attribute for that connection) is different from the connection ID of the previous connection.

CLIENT-TTY attribute

Returns the name of the terminal display for this user’s login session. If not specified, the AVM returns a zero-length character string.
CLIENT-TYPE attribute

Returns the type of ABL client currently executing.

**Data type:** CHARACTER
**Access:** Readable
**Applies to:** SESSION system handle

Table 69 shows the value of CLIENT-TYPE for each supported client type.

<table>
<thead>
<tr>
<th>Type of client</th>
<th>Attribute value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProVision standard ABL client</td>
<td>4GLCLIENT</td>
</tr>
<tr>
<td>WebClient</td>
<td>WEBCLIENT</td>
</tr>
<tr>
<td>AppServer agent</td>
<td>APPSERVER</td>
</tr>
<tr>
<td>WebSpeed agent</td>
<td>WEBSPEED</td>
</tr>
<tr>
<td>Other special-purpose clients</td>
<td>Unknown value (?)</td>
</tr>
</tbody>
</table>

CLIENT-WORKSTATION attribute

The name of the host workstation on which the user, represented by the Client-principal object, is working. If not specified, the AVM returns a zero-length character string.

**Data type:** CHARACTER
**Access:** Readable/Writeable
**Applies to:** Client-principal object handle

Once the Client-principal object is sealed, this attribute is read-only.
CLONE-NODE( ) method

Clone the XML node referred to by a node reference. The first parameter must be a valid
X-noderef handle and refers to the new cloned XML node if the method succeeds. The new node
is associated with the same document, but needs to be inserted with INSERT-BEFORE( ) or
APPEND-CHILD( ) to become part of the document structure.

Return type: LOGICAL
Applies to: X-noderef object handle

Syntax

```
CLONE-NODE( x-node-handle, deep )
```

**x-node-handle**

A valid X-noderef handle to use for the new XML node.

**deep**

A logical that if TRUE specifies that the whole sub-tree is to be cloned. The default value
is FALSE.

The following example demonstrates the use of the CLONE-NODE( ) method to clone an entire
sub-tree:

```
h01dNode:CLONE-NODE(hNewNode, true).
```

CLOSE-LOG( ) method

Closes the current log file, which stops an interactive or batch client from writing messages to
the log file.

The CLOSE-LOG( ) method writes a message to the log file indicating that the client
intentionally closed the log file, so that the user knows why there are no more messages in the
log file.

Return type: LOGICAL
Applies to: LOG-MANAGER system handle

Syntax

```
CLOSE-LOG( )
```

If the CLOSE-LOG( ) method successfully closes the open log file, it returns TRUE.

If the CLOSE-LOG( ) method fails, it returns FALSE and displays a warning message
indicating the reason for the failure.
If there is no client log file, the CLOSE-LOG( ) method returns TRUE and does not display a warning message.

**Notes:** This method is valid only for interactive and batch clients. WebSpeed agents and AppServer servers write a message to the server log file indicating that it is invalid to use the CLOSE-LOG( ) method to close a WebSpeed or AppServer server log file. In this case, the method returns FALSE.

Unlike the other LOG-MANAGER methods, you cannot use this method with the DSLOG-MANAGER system handle.

---

**CODE attribute**

A numeric code associated with the last event.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** LAST-EVENT system handle

For keyboard and mouse events (EVENT-TYPE attribute set to "KEYPRESS" or "MOUSE"), this is the key code. For high-level ABL events (EVENT-TYPE attribute set to "PROGRESS"), this is a unique numeric value greater than the key code values. For information on key codes, see the chapter on handling user input in *OpenEdge Development: Programming Interfaces*.

If a mouse event is high-level mouse event (for example, MOUSE-SELECT-CLICK), this attribute is set to the key code of the low-level mouse event (for example, MOUSE-SELECT-UP) that triggered the high-level event. To determine the triggered high-level event, you must also check the value of the FUNCTION attribute, in this case "MOUSE-SELECT-CLICK".

---

**CODEPAGE attribute**

The code page of specified r-code.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** RCODE-INFO system handle

This attribute references the code page of the strings in the text segment. The code page value is written to the r-code file when the file is saved. ABL uses the code page specified by the R-code Out Code Page (-cprcodeout) startup parameter to write the r-code text segment. If -cprcodeout is not specified, ABL uses the value of the Internal Code Page (CPINTERNAL) SESSION handle.

For a file that is session compiled, the return value is the Unknown value (?).  

---

1351
COLUMN attribute

The column position of the left edge of the widget or the column position of the mouse cursor for the last mouse event on the display.

**Data type:** DECIMAL  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LAST-EVENT system handle, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

For browse cells, field groups, and the LAST-EVENT handle, it is readable only.

For all widgets except windows, the COLUMN attribute specifies the location, in character units, of the left edge of the widget relative to the left edge of its parent widget. In windows, the location is relative to the left edge of the display.

For browse columns, the COLUMN attribute returns the Unknown value (?) if the column is hidden.

For control-frames, the COLUMN attribute maps to the Left property of the control-frame COM object (ActiveX control container).

For the LAST-EVENT handle, the COLUMN attribute specifies the column location, in character units, of the last mouse event relative to the left edge of the current frame.

This attribute is functionally equivalent to the X attribute.

COLUMN-BGCOLOR attribute

The color number of the background color for the columns in a browse widget.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (column)

The color number represents an entry in the color table maintained by the COLOR-TABLE handle.

COLUMN-DCOLOR attribute

(Character interfaces only)

The number of the display color of a column.
<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>
COLUMN-PFCOLOR attribute

The color number for the display color of a column with input focus.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (column)

Overrides the color specified for the entire browse widget to display a single column in the specified color.

The color number represents an entry in the color table maintained by the COLOR-TABLE handle.

COLUMN-READ-ONLY attribute

Indicates whether you can tab to a browse column but not edit it.

**Data type:** LOGICAL

**Access:** Readable/Writable

**Applies to:** BROWSE widget (column)

For combo-box browse columns, this attribute is read-only and always returns FALSE.
COLUMN-RESIZABLE attribute

(Graphical interfaces only)

Indicates whether you can resize a browse column by pointing, clicking, and dragging.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BROWSE widget

If COLUMN-RESIZABLE is TRUE, you can resize any of the browse’s browse columns by pointing, clicking, and dragging on a column separator. This attribute lets you turn on and off the ability of end users to resize browse columns. IF COLUMN-RESIZABLE is TRUE, the START-RESIZE and END-RESIZE events for the browse column take precedence over all other events.

When you set a browse’s COLUMN-RESIZABLE attribute to a certain value, the AVM automatically sets the RESIZABLE attribute of the browse’s browse columns to the same value. For more information on the RESIZABLE attribute, see the RESIZABLE attribute reference entry.

If you add the ResizelnCell option to the [Startup] section of the progress.ini file and set it to YES, you limit the user’s ability to change the browse column size to only at the column label cell’s separator. If a column does not have a label, the user cannot change the size of that column.

If the ResizelnCell option is set to NO, you get the default behavior where the user can change the column size at any place on the column separator.

COLUMN-SCROLLING attribute

(Windows only)

The horizontal scrolling behavior of a browse widget.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BROWSE widget

If the COLUMN-SCROLLING attribute is TRUE, horizontal scrolling for the browse widget moves in whole-column increments. If a column is wider than the browse widget, you cannot see the text if the right side of the column, but you can still scroll to the next column.

If the attribute is FALSE, horizontal scrolling for the browse widget moves in increments equal to the pixel width of the average character in the current browse font. In this case, if a column is wider than the browse, you can view it by scrolling through the column in these increments.
The default value is TRUE for a static browse, and FALSE for a dynamic browse.

**COM-HANDLE attribute**

(Windows only)

The component handle to the control-frame COM object.

- **Data type:** COM-HANDLE
- **Access:** Readable
- **Applies to:** CONTROL-FRAME widget

This handle provides access to the ActiveX control container (COM object) associated with the control-frame. You can use this, in turn, to access control-frame COM object properties and methods.

For information on the properties and methods on the control-frame COM object, see the CONTROL-FRAME widget reference entry. For information on accessing COM object properties and methods, see the “Accessing COM object properties and methods” section on page 1277.

**COMPLETE attribute**

Indicates if the asynchronous request is completed and its result is processed on the client.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Asynchronous request object handle

If set to FALSE, the PROCEDURE-COMPLETE event on this handle has not yet been returned from the AppServer running the request. This attribute is set to TRUE when the AppServer returns the PROCEDURE-COMPLETE event and immediately before any specified event procedure executes.

**CONFIG-NAME attribute**

The WebSpeed service name. This method is called by the get-config WebSpeed API function. Intended for internal use only.
**CONNECT( ) method (AppServer)**

Physically connects and associates an AppServer instance, or logically connects an application service, with the specified server handle. The current application becomes a client application of the connected AppServer.

**Return type:** LOGICAL  
**Applies to:** Server object handle

**Syntax**

```
CONNECT ( [ connection-parms ] [ , userid ] [ , password ] [ , app-server-info ] )
```

All of the parameters for the CONNECT( ) method are optional and have defaults if you do not specify them.

**connection-parms**

A character string containing a space-separated list of one or more connection parameters necessary to establish an AppServer connection. These parameters include two types:

- A basic set used to connect to an AppServer instance or application service, regardless of the session model
- A set for specifying and managing the session model of the connection

**Table 70** describes the basic connection parameters you must specify to connect to an AppServer instance or application service, regardless of the session model.

**Table 70: AppServer basic connection parameters**

<table>
<thead>
<tr>
<th>Connection parameter¹</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-AppService application-service</td>
<td>If you connect through a NameServer, the name of an Application Service supported by the specified NameServer. (Defaults to the default service for the specified Name Server.) If you connect directly to an AppServer, this parameter is ignored.</td>
</tr>
<tr>
<td>-H [ host_name</td>
<td>IP-address ]</td>
</tr>
</tbody>
</table>
The UDP port number for a NameServer, or, if you connect directly, the TCP/IP port number for an AppServer connection. You can specify either an explicit port number or a service name. If you use a service name, the method uses the port number associated with that name in the TCP/IP services file. (Defaults to 5162)

If specified, the -H and -S parameters are interpreted as the network address and TCP/IP port number of an AppServer connection. Otherwise, the -H and -S parameters are interpreted as the network address and UDP port number of a NameServer.

If specified, the connection is direct to the AppServer using Secure Sockets Layer (SSL) tunneling.

(Used in conjunction with the -AppService, -H, and -S parameters).

**Note:** Be sure you need SSL before using this option. SSL incurs more or less heavy performance penalties, depending on resources and load.

If specified, the connection does not reuse the SSL session ID when reconnecting to the same SSL-enabled server (either a Web server with HTTPS or an SSL-enabled AppServer).

If specified, turns off host verification for an SSL-enabled connection, either using HTTPS with the AIA or using a direct connection to an SSL-enabled AppServer. Without this parameter specified, the client compares the host name specified in the connection with the Common Name specified in the server certificate, and raises an error if they do not match. With this parameter specified, the client never raises the error. For more information, see *OpenEdge Getting Started: Core Business Services*.

A text file containing any of the other AppServer connection parameters described in this table or Table 71. If this file contains any other OpenEdge startup parameters, the method ignores them.
Note: Connections to an Internet-secure (HTTPS) or SSL-enabled AppServer require the management of public keys on the client (SSL client) and private keys on the server (SSL server). For an Internet-secure AppServer, the SSL server is the Web server that hosts the AIA. For an SSL-enabled AppServer, the SSL server is the AppServer itself. For information on configuring a Web server for HTTPS, see your Web server documentation. For information on using SSL to secure an AppServer, see *OpenEdge Application Server: Developing AppServer Applications*. For information on configuring an AppServer for SSL tunneling, see *OpenEdge Application Server: Administration*. For information on managing private key and digital certificate stores for SSL clients and servers, see *OpenEdge Getting Started: Core Business Services*.

Table 71 describes connection parameters for specifying and managing the session model of the connection.
## Table 71: AppServer session model connection parameters

<table>
<thead>
<tr>
<th>Connection parameter</th>
<th>Session model/ default</th>
<th>Description</th>
</tr>
</thead>
</table>
| -sessionModel        | Session-managed        | Session model supported by the AppServer operating mode, specified by one of the following values:  
 • Session-managed  
 • Session-free  
 This value is not case sensitive.  
 This parameter is required for session-free applications and is optional for session-managed applications.  
 This value must match the AppServer operating mode or the CONNECT( ) method fails.  
 The default value is Session-managed. |
| -connectionLifetime  | Session-free           | The maximum number of seconds that a given connection can be used before it is destroyed. Connections whose lifetime exceeds the specified value are destroyed as they become available.  
 An available connection is one that is not currently reserved to run a request. Bound connections associated with remote persistent procedures are not available for re-use until the persistent procedure is deleted. So, bound connections remain available as long as necessary, even if they exceed the specified value.  
 The default value is 300 seconds. |
| -initialConnections  | Session-free           | The number of connections established when the CONNECT( ) method executes on a given server handle. The value must be greater than zero.  
 If the specified number of connections cannot be created, the CONNECT( ) method fails and any successfully-created connections are closed.  
 The default value is 1. |
The maximum number of connections that can be created for a given server handle to execute non-persistent external procedures. The value must be greater than or equal to zero. If this value is zero, there is no limit to the number of connections that can be created.

**Note:** For calls to persistent procedures, their internal procedures, and user-defined functions, the client has no limit on the number of connections that can be created.

The default value is 0.

The maximum value for the UDP port number used by the client when communicating with the NameServer. If this value is zero, the AVM chooses the NameServer client port randomly. This value should be greater than or equal to the value of the `-nsClientMinPort` parameter.

The default value is 0.

The minimum value for the UDP port number used by the client when communicating with the NameServer. If this value is zero, the AVM chooses the NameServer client port randomly.

The default value is 0.

The maximum amount of time, in seconds, that the client retains an AppServer pick list for an application service.

The default value is 300.

The number of AppServer picks to request from the NameServer each time it looks up the available AppServer connections for a given application service name.

The default value is 1.

<table>
<thead>
<tr>
<th>Connection parameter</th>
<th>Session model/default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>maxConnections</code></td>
<td>Session-free</td>
<td>The maximum number of connections that can be created for a given server handle to execute non-persistent external procedures. The value must be greater than or equal to zero. If this value is zero, there is no limit to the number of connections that can be created. The default value is 0.</td>
</tr>
<tr>
<td><code>-nsClientMaxPort portNum</code></td>
<td>Session-manage Session-free</td>
<td>The maximum value for the UDP port number used by the client when communicating with the NameServer. If this value is zero, the AVM chooses the NameServer client port randomly. This value should be greater than or equal to the value of the <code>-nsClientMinPort</code> parameter. The default value is 0.</td>
</tr>
<tr>
<td><code>-nsClientMinPort portNum</code></td>
<td>Session-manage Session-free</td>
<td>The minimum value for the UDP port number used by the client when communicating with the NameServer. If this value is zero, the AVM chooses the NameServer client port randomly. The default value is 0.</td>
</tr>
<tr>
<td><code>-nsClientPicklistExpiration nSeconds</code></td>
<td>Session-free</td>
<td>The maximum amount of time, in seconds, that the client retains an AppServer pick list for an application service. The default value is 300.</td>
</tr>
<tr>
<td><code>-nsClientPicklistSize nPicks</code></td>
<td>Session-free</td>
<td>The number of AppServer picks to request from the NameServer each time it looks up the available AppServer connections for a given application service name. The default value is 1.</td>
</tr>
</tbody>
</table>
Table 71: AppServer session model connection parameters

<table>
<thead>
<tr>
<th>Connection parameter</th>
<th>Session model/default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-nsClientPortRetry nRetries</td>
<td>Session-manage Session-free</td>
<td>The maximum number of attempts that the client makes to get a valid local UDP port number when attempting to communicate with the NameServer. The default value is 0.</td>
</tr>
<tr>
<td>-nsClientDelay nMilliseconds</td>
<td>Session-manage Session-free</td>
<td>The interval, in milliseconds, that the client waits between attempts to get a valid UDP port number when attempting to communicate with the NameServer. The default value is 0.</td>
</tr>
</tbody>
</table>

Note that the actual AppServer that the client connects to is controlled by the NameServer based on the application service (-AppService) name specified by the client. The ABL interface in cooperation with the NameServer connect the client application to one of the AppServer instances that supports the specified application service. If you do not specify an application service, the NameServer uses whatever AppServer registers itself as the default service, if any. For more information on load balancing, see the information on NameServers and load balancing in *OpenEdge Application Server: Developing AppServer Applications* and the AppServer administration chapter in *OpenEdge Application Server: Administration*.

If the application service is unknown to the NameServer, the client application receives an error. Otherwise, the connection proceeds and any configured Connect procedure executes for the connected AppServer.

For more information on application services and NameServers, see *OpenEdge Application Server: Developing AppServer Applications*.

```
[ userid ] [ , password ] [ , app-server-info ]
```

From one to three character string parameters passed as input to the AppServer Connect procedure. The possible values that you can specify for these parameters is determined by the Connect procedure for the AppServer application. If you omit a parameter, it defaults to the Unknown value (?).

If an error occurs while executing the CONNECT() method, the method returns FALSE. Otherwise, it returns TRUE. An error can occur if:

- The server handle is invalid.
- One of the parameters contains an invalid value.
- One of the values specified in the connection-parms parameter is invalid.
- The Name Server cannot be located.
- The specified Application Service is not registered to a NameServer.
The client application cannot connect to the AppServer selected by the NameServer.

The AppServer selected by the NameServer cannot allocate a connection for the client application.

The AppServer executes a Connect procedure that terminates with a STOP condition, a QUIT condition, or after executing a RETURN ERROR statement. For more information on Connect procedures, see *OpenEdge Application Server: Developing AppServer Applications*.

If the CONNECT( ) method completes successfully, the CONNECTED( ) method returns TRUE.

The connection lasts until the client application executes the server handle DISCONNECT( ) method or until the AVM detects any failure conditions that automatically terminate the connection.

The -URL connection parameter allows you to connect to an AppServer using the AppServer Internet Adapter (AIA) with the following protocols: HTTP and HTTPS.

For more information on AppServers or the AppServer Internet Adapter (AIA), see *OpenEdge Application Server: Developing AppServer Applications*.

---

**CONNECT( ) method (Socket object)**

Connects a socket to the specified TCP/IP port on the specified host.

**Return type:** LOGICAL

**Applies to:** Socket object handle

**Syntax**

```plaintext
CONNECT ( [ connection-parms ] )
```

**connection-parms**

A character string expression that contains a space-separated list of one or more socket connection parameters.

Table 72 describes each socket connection parameter, which can be included in this string.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-H socket-address</td>
<td>Optional. The host name or IP address to which the connection is to be established.</td>
</tr>
<tr>
<td>-S socket-port</td>
<td>The port number for the socket connection. You can specify either an explicit port number or a TCP service name. If you use a TCP service name, the method uses the port number associated with that name in the TCP/IP services file.</td>
</tr>
</tbody>
</table>
If an error occurs while executing the `CONNECT( )` method, the method returns FALSE. Otherwise, it returns TRUE.

When an ABL client (that is not SSL-enabled) calls the `CONNECT( )` method and immediately reads data from the socket using the `READ( )` method, and an ABL server (that is SSL-enabled) calls the `ENABLE-CONNECTIONS( )` method and immediately writes data to the socket using the `WRITE( )` method, a deadlock condition can occur. That is, the client is waiting for the server to send data, and the server (regardless of the Write operation) is waiting for the client connection to send data that starts the SSL connection.

---

### Table 72: Socket connection parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-ssl</code></td>
<td>If specified, the connection to the server socket uses Secure Sockets Layer (SSL) tunneling. (Used in conjunction with the <code>-H</code> and <code>-S</code> parameters.)</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: Be sure you need SSL before using this option. SSL incurs more or less heavy performance penalties, depending on resources and load.</td>
</tr>
<tr>
<td><code>-nosessionreuse</code></td>
<td>If specified, the connection does not reuse the SSL session ID when reconnecting to the same SSL-enabled server socket.</td>
</tr>
<tr>
<td><code>-nohostverify</code></td>
<td>If specified, turns off host verification for an SSL-enabled connection to a server socket. Without this parameter specified, the client compares the host name specified in the connection with the Common Name specified in the server certificate, and raises an error if they do not match. With this parameter specified, the client never raises the error. For more information, see <em>OpenEdge Getting Started: Core Business Services</em>.</td>
</tr>
<tr>
<td><code>-pf filename</code></td>
<td>Optional. A text file containing any of the socket connection parameters described in this table. If this file contains any other OpenEdge startup parameters, this method ignores them.</td>
</tr>
</tbody>
</table>

---

**Note**: Connections to an SSL-enabled server socket require the management of public keys on the client (SSL client) and private keys on the server (SSL server). For ABL sockets, the SSL client is the ABL session initiating the SSL connection on a socket object and the SSL server is the ABL session enabling SSL connections on a server socket object. For information on using SSL to secure an ABL socket connection, see the sections on sockets in *OpenEdge Development: Programming Interfaces*. For more information on SSL and managing private key and digital certificate stores for OpenEdge SSL clients and servers, see *OpenEdge Getting Started: Core Business Services*.
CONNECT() method (Web service)

Connects to and associates a Web service instance with the specified server handle. The current application becomes a client application of the connected Web service.

**Return type:** LOGICAL  
**Applies to:** Server object handle

**Syntax**

```
CONNECT ( [ connection-parms ] )
```

**connection-parms**

A character string containing a space-separated list of one or more connection parameters.

Table 73 describes each Web service connection parameter you can include in this string. This method ignores any other strings included in this parameter.

**Table 73:** Web service connection parameters  

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-WSDL wsdl-document</td>
<td>The location of the WSDL document. This required parameter is the URL, UNC, or local file pathname to the WSDL file that describes the Web service. The document can be local or remote. The location can optionally contain a user’s account name and password to use when connecting to the Web Server. For more information, see the “-WSDL parameter security options” section on page 1367. If the protocol is not part of the wsdl-document’s URL, the ‘file’ protocol is assumed. Additionally, the ‘file’ can be a relative pathname as it is relative to the current working directory.</td>
</tr>
<tr>
<td>-WSDLUserid user-id</td>
<td>Optional user account name to use in connecting to the Web service that hosts the WSDL document. If -WSDLUserid is specified and -WSDLPassword is not, the AVM uses a blank password.</td>
</tr>
<tr>
<td>-WSDLPassword password</td>
<td>Optional password to use with -WSDLUserid. This attribute is ignored if -WSDLUserid is not specified.</td>
</tr>
<tr>
<td>-Service service-name</td>
<td>The local name of the service element within the WSDL document that the application will use. This field is optional. Many WSDL documents only support one service and this parameter is optional if there is only one (or zero) service elements defined. Used in conjunction with -Port.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>-ServiceNamespace</code></td>
<td>The namespace of the service element within the WSDL document that the application will use. Most WSDL documents only support one service and this parameter is optional if there is only one service defined. This parameter is used in conjunction with <code>-Service</code> and is ignored if <code>-Service</code> was not specified. This parameter is optional, if the namespace is included in <code>-Service</code>.</td>
</tr>
<tr>
<td><code>-Port port-name</code></td>
<td>The local name of the port element contained within the service element. Used in conjunction with <code>-Service</code>. This parameter is optional if <code>-Service</code> contains only one port.</td>
</tr>
<tr>
<td><code>-Binding binding-name</code></td>
<td>The local name of the binding element contained in the WSDL document. Used in conjunction with <code>-SoapEndpoint</code>. This parameter is optional if the WSDL contains only one binding.</td>
</tr>
<tr>
<td><code>-BindingNamespace</code></td>
<td>The namespace of the binding element within the WSDL document that the application will use. This optional field is needed only if the local binding-name is not unique.</td>
</tr>
<tr>
<td><code>-SOAPEndpoint URL-endpoint</code></td>
<td>The URL identifying the endpoint for this Web service. Used in conjunction with <code>-Binding</code>. It is an error to use this parameter in conjunction with <code>-Service</code> or <code>-Port</code>.</td>
</tr>
<tr>
<td><code>-SOAPEndpointUserid user-id</code></td>
<td>Optional user account name to use to connect to a Web service that hosts the Web Server application. If <code>-SOAPEndpointUserid</code> is specified and <code>-SOAPEndpointPassword</code> is not, the AVM uses a blank password.</td>
</tr>
<tr>
<td><code>-SOAPEndpointPassword password</code></td>
<td>Optional password to use with the <code>-SoapEndpointUserid</code>. This attribute is ignored if <code>-SoapEndpointUserid</code> is not specified.</td>
</tr>
<tr>
<td><code>-TargetNamespace</code></td>
<td>The namespace contained in the WSDL document. This parameter can be used as a version check. The information in this parameter is compared against the <code>-TargetNamespace</code> contained in the WSDL document. If they do NOT match the CONNECT () method fails.</td>
</tr>
</tbody>
</table>
Table 73: Web service connection parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-connectionLifetime nSeconds</td>
<td>The maximum number of seconds that a given connection can be reused for asynchronous requests before it is destroyed. Connections whose lifetime exceeds the specified value are destroyed as they become available. An available connection is one that is not currently reserved to run an asynchronous request. The default value is 300 seconds.</td>
</tr>
<tr>
<td>-maxConnections num-connections</td>
<td>Maximum number of connections maintained between the client and the Web Server for asynchronous requests. If num connections is less than or equal to 0, the application is requesting no predefined limit on the number of connections. If the client application exceeds the specified number of connections, the asynchronous requests are queued. The default value is 0.</td>
</tr>
<tr>
<td>-nosessionreuse</td>
<td>If specified, the connection does not reuse the SSL session ID when reconnecting to the same HTTPS-enabled Web server.</td>
</tr>
<tr>
<td>-nohostverify</td>
<td>If specified, turns off host verification for an HTTPS Web server connection. Without this parameter specified, the client compares the host name specified in the connection with the Common Name specified in the server certificate, and raises an error if they do not match. With this parameter specified, the client never raises the error. For more information, see OpenEdge Getting Started: Core Business Services.</td>
</tr>
<tr>
<td>-pf filename</td>
<td>A text file containing any of the other Web service binding parameters described in this table. If this file contains any other OpenEdge startup parameters, this method ignores them.</td>
</tr>
</tbody>
</table>

**Note:** Connections to an Internet-secure (HTTPS) Web service require the management of public keys on the client (HTTPS client) and private keys on the server (HTTPS server). For an Internet-secure Web service, the HTTPS server is the Web server that hosts the Web service. For information on configuring a Web server for HTTPS, see your Web server documentation. For more information on HTTPS and SSL, and on managing private key and digital certificate stores for OpenEdge SSL clients and servers, see OpenEdge Getting Started: Core Business Services.

**-WSDL parameter security options**

The -WSDL parameter can optionally contain a user account name and password to use to connect to a Web Server. This is the syntax for specifying the parameter using the HTTP and HTTPS protocols, respectively:
CONNECT( ) method (Web service)

Syntax

-WSDL
http://[user-id[:password]@]web-server-host[:web-server-port]WSDL-path

-WSDL
https://[user-id[:password]@]web-server-host[:web-server-port]WSDL-path

user-id

User account name to use to connect to a Web service that hosts the WSDL document. If user-id is specified and password is not, the AVM uses a blank password.

password

Password to use with the user-id. This parameter is ignored if user-id is not specified.

web-server-host

TCP/IP host address of the Web Server that hosts the WSDL document.

web-server-port

TCP/IP port address of the Web Server that host the WSDL document. The default port is 80 for HTTP and 443 for HTTPS.

WSDL-path

URL path to the WSDL document for the Web service.

Instead of building the account name and password into the WSDL string, you can specify the account name using the -WSDLUserid parameter and the password using the -WSDLPassword parameter. If these parameters are used and the WSDL URL (WSDL-path) also contains a user id and password, the information on the WSDL URL is used.

Connection parameter combinations

The CONNECT( ) method is used to connect an ABL SERVER object to a specific application service. This service can be either an AppServer or a Web service. Independent of the type of application service to which the client is connecting, the client needs to provide the location of the service and transport information. There are two mechanisms for providing this information when connecting to a Web service:

1. The CONNECT( ) method can identify a specific service element name and port element name from the WSDL document. The combination of these two element names identify the location of a set of operations that are available on the Web service. It also identifies the transport data. The service element name is specified with the -Service connection parameter and the port element name is specified with the -Port connection parameter.

If the WSDL document contains several service elements, the CONNECT method must identify which service element the client wants to connect to, via -Service. If the WSDL document only identifies one service element, the CONNECT method does not need to contain the service element name. Similarly if the WSDL document (or if the identified
service element) only identifies one port element, the CONNECT method does not need to contain the port element name.

If the application needs to provide account name and password information, it can accomplish this by providing the account name and password information in the -SoapEndpointUserid and -SoapEndpointPassword parameters.

If the WSDL document identifies multiple service elements with the same local name, the CONNECT( ) method must also contain the -ServiceNamespace connection parameter.

2. If the WSDL document contains several binding elements, the CONNECT method must identify which binding element the client wants to use, via the -Binding parameter. If the WSDL document only identifies one binding element, the CONNECT method does not need to contain the binding element name.

If the application needs to provide account name and password information, it can accomplish this by providing the account name and password information in the -SoapEndpointUserid and -SoapEndpointPassword parameters.

If the WSDL document identifies multiple binding elements with the same local name, the CONNECT( ) method must also contain the -BindingNamespace connection parameter.

If an error occurs while executing the CONNECT( ) method, the method returns FALSE. Otherwise, it returns TRUE. An error can occur if:

- The server handle is invalid.
- One of the parameters contains an invalid value.
- One of the values specified in the connection-parms parameter is invalid.
- The -TargetNamespace does not match the value contained in the WSDL document.
- The WSDL document cannot be located.
- The -WSDLUserId or -WSDLPassword is not valid.

If the CONNECT( ) method completes successfully, the CONNECTED( ) method returns TRUE.

The connection lasts until the client application executes the server handle DISCONNECT( ) method or until the AVM detects any failure condition that automatically terminates the connection.

**CONNECTED( ) method**

Indicates whether an AppServer or Web service is currently connected and associated with the server handle, or if a socket handle is currently connected to a port.

**Note:** For a Web service, this method indicates if a server handle is currently connected to a Web service (that is, if the client has a logical connection to the Web service). It does not indicate that a physical connection exists between the ABL client and the Web service.
**CONNECTED ( )**

For a state-reset, state-aware, or stateless AppServer, this method returns TRUE if the AppServer is currently connected and associated with the server handle. For a state-free AppServer, this method returns TRUE if the CONNECT( ) method has been successfully executed for an application service associated with this handle and at least one AppServer resource is available for the client to access this application service.

For a Web service, this method returns TRUE if the server handle refers to a connected Web service, and returns FALSE otherwise.

This method returns TRUE between the successful invocation of the CONNECT( ) method and a call to the DISCONNECT( ) method. If a server handle was connected to an AppServer or Web service, but the connection terminated abnormally (that is, other than by the DISCONNECT( ) method), the CONNECTED( ) method returns FALSE.

**Note:** This method returning TRUE does not indicate the state of the HTTP connection to the Web service. If there is a failure in the connection between the client and the Web service, subsequent requests might fail.

For a socket object, this method returns TRUE if the socket handle refers to a connected socket, and returns FALSE otherwise.

For more information on AppServers, see *OpenEdge Application Server: Developing AppServer Applications*.

---

**CONTEXT-HELP attribute**

*(Windows only)*

When CONTEXT-HELP is TRUE, a question mark icon displays in the title bar of the window or dialog box. The default value is FALSE. This attribute must be set before the window or dialog box is realized.

**Return type:** LOGICAL

**Access:** Readable/Writable

**Applies to:** DIALOG-BOX widget, WINDOW widget

Due to bugs in Microsoft Windows, the question mark icon does not appear, or appears but does not function, when combined with other attribute settings that affect a window’s title bar:

- If CONTEXT-HELP = TRUE and SMALL-TITLE = TRUE, the question mark icon does not appear.
- If CONTEXT-HELP = TRUE and both MIN-BUTTON = TRUE and MAX-BUTTON = TRUE, the question mark icon does not appear.
- If CONTEXT-HELP = TRUE and either (but not both) of MIN-BUTTON or MAX-BUTTON = TRUE, the question mark icon appears but does not function.

- If CONTEXT-HELP = TRUE and CONTROL-BOX = FALSE, the question mark icon does not appear.

To summarize, you must set CONTEXT-HELP = TRUE, MIN-BUTTON = FALSE, and MAX-BUTTON = FALSE (leaving CONTROL-BOX at its default value of TRUE and SMALL-TITLE at its default value of FALSE) in order to successfully use this feature with a window widget.

**Note:** The preceding settings only apply to window widgets, not to dialog boxes. The question mark icon always functions correctly when used with a dialog box.

---

**CONTEXT-HELP-FILE attribute**

*Windows only*

Specifies the path name of a help (.HLP) file associated with a dialog box, window, or session.

**Return type:** CHARACTER

**Access:** Readable/Writable

**Applies to:** SESSION system handle, DIALOG-BOX widget, WINDOW widget

If CONTEXT-HELP-FILE is not specified (is unknown) for a dialog box, the dialog box inherits the help file of its parent window. If the parent window’s CONTEXT-HELP-FILE is also unknown, it inherits the session’s help file (specified by SESSION:CONTEXT-HELP-FILE). The full pathname of the help file should be given. The AVM does not search for the help file.

---

**CONTEXT-HELP-ID attribute**

*Windows only*

Specifies the identifier of a help topic in a help file.

**Return type:** INTEGER

**Access:** Readable/Writable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

---

**CONTROL-BOX attribute**

*Windows only*

Indicates whether the window has a system menu box in its caption bar.
**Control-Name property**

*Data type:* LOGICAL  
*Access:* Readable/Writable  
*Applies to:* WINDOW widget

In character interfaces, this attribute has no effect.

The CONTROL-BOX attribute must be set before the window is realized. The default value is TRUE.

---

**Control-Name property**  
*(Windows only; Graphical interfaces only)*

The component handle to an ActiveX control that has the specified design-time name *(Control-Name)* and that is loaded into the control-frame.

*Data type:* COM-HANDLE  
*Access:* Readable  
*Applies to:* CONTROL-FRAME widget, COM object

Another way of getting a component handle to an ActiveX control is to access it through the control collection. For more information, see the Controls property entry.

References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

To return the component handle of the ActiveX control, you provide the design-time name as a property of the control-frame COM object. In the following example, Spin is the name of an ActiveX control and is also used as a property to return the handle to that control:

```plaintext
DEFINE VARIABLE hSpin AS COM-HANDLE NO-UNDO.  
DEFINE VARIABLE hControlFrameCOM AS COM-HANDLE NO-UNDO.  
DEFINE VARIABLE hControlFrame AS HANDLE NO-UNDO.  
/* Instantiate the control-frame with hControlFrame and load the Spin control into it*/  
hControlFrameCOM = hControlFrame:COM-HANDLE.  
hSpin = hControlFrameCOM:Spin.  
```

This is the simplest technique to access an ActiveX control that is loaded in a control frame.

---

**Controls property**  
*(Windows only; Graphical interfaces only)*

The component handle to the control collection that references the ActiveX controls in the control-frame.
CONVERT-3D-COLORS attribute

Determine whether image colors are converted to the corresponding system 3D colors.

**Return type:** LOGICAL

**Access:** Readable/Writable

**Applies to:** BUTTON widget, IMAGE widget

The default value of this attribute for a button is TRUE; the default value for an image is FALSE.

The CONVERT-3D-COLORS attribute can be set after a widget is realized, but it will not take effect until an image is loaded into the widget using one of the following methods: LOAD-IMAGE( ), LOAD-IMAGE-UP( ), LOAD-IMAGE-DOWN( ), or LOAD-IMAGE-INSENSITIVE( ).

If the CONVERT-3D-COLORS attribute is TRUE either when the widget is realized or when any of the LOAD-IMAGE methods is executed, the AVM will convert the shades of gray in the image after loading it. Table 74 identifies and describes the colors that are converted.

<table>
<thead>
<tr>
<th>If the color is . . .</th>
<th>And the original Red-Green-Blue (RGB) color value is . . .</th>
<th>Then the new converted system color is . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>White</td>
<td>(255, 255, 255)</td>
<td>System button highlight color</td>
</tr>
<tr>
<td>Light Gray</td>
<td>(192, 192, 255)</td>
<td>System button face color</td>
</tr>
</tbody>
</table>
CONVERT-TO-OFFSET( ) method

Converts a row and column value to a character offset in an editor widget.

Return type: INTEGER
Applies to: EDITOR widget

Syntax

CONVERT-TO-OFFSET ( row , column )

row

An integer row number.

column

An integer column number.

In Windows, both the regular editor and the large editor support CONVERT-TO-OFFSET.

COPY-DATASET( ) method

Copies a source ProDataSet object to a target ProDataSet object. The AVM empties the target ProDataSet object temp-tables of all records before copying the source ProDataSet object, by default.

Return type: LOGICAL
Applies to: ProDataSet object handle

Syntax

targ-dataset-handle

The handle to the target ProDataSet object to receive the copy.
**Copied from the document:**

**COPY-DATASET( ) method**

*src-dataset-handle*

The handle to the source ProDataSet object from which to copy.

*append-mode*

An optional logical expression where TRUE indicates that the AVM copy the ProDataSet object temp-tables in an *append* mode.

When TRUE, the AVM appends the source ProDataSet temp-tables to the target ProDataSet temp-tables. If there is a unique index on a target temp-table and the AVM finds a row with a duplicate key, it does not replace the row. If there is not a unique index on the target temp-table, the AVM appends the data row from the source temp-table to the target temp-table, which might result in duplicate rows. If this operation results in duplicate rows, the AVM does not generate a run-time error.

**Note:** In this mode, the AVM treats duplicate temp-table rows during the copy operation in the same way it treats duplicate temp-table rows during a fill operation in MERGE mode.

When you are certain the ProDataSet temp-tables do not contain duplicate rows, copying the ProDataSet object in append mode is more efficient than copying it in replace mode.

When FALSE, the AVM does not append records in the target ProDataSet temp-tables. The default value is FALSE.

The AVM ignores this expression when *replace-mode* is TRUE.

*replace-mode*

An optional logical expression where TRUE indicates that the AVM copy the ProDataSet object temp-tables in a *replace* mode.

When TRUE, the AVM replaces records in the target ProDataSet object temp-tables with corresponding records from the source ProDataSet temp-tables. The target temp-table must have a unique primary index that the AVM can use to find the corresponding records. When a corresponding record is found in the target temp-table, the AVM replaces the target record with the source record. When a corresponding record is not found in the target temp-table, the AVM creates a new target record using the source record. If the before-image table associated with the target temp-table contains a row for the target record, the row is left in place.

Copying ProDataSet object temp-tables in replace mode is less efficient than copying them in append mode. When you are certain the ProDataSet object temp-tables do not contain duplicate rows, copy the ProDataSet object in append mode.

When FALSE, the AVM does not replace records in the target ProDataSet object temp-tables. The default value is FALSE.

*loose-copy-mode*

An optional logical expression where TRUE indicates that the AVM copy the ProDataSet object temp-tables in a *loose-copy* mode. That is, it relaxes the requirement that the metaschema for the source and target temp-tables be the same.
COPY-DATASET( ) method

When TRUE, the AVM copies each temp-table in the source ProDataSet object to the target ProDataSet object based on a field mapping between the source and target temp-table buffers. If there is an attached data source with a field mapping, the AVM uses that field mapping to copy fields from each source temp-table buffer to its target temp-table buffer. If there are fields in either buffer that do not exist in the other, they are ignored. If there is no field mapping with the attached data source, or there is no attached data source, the AVM copies only those fields with the same name that appear in both the source and target temp-table metaschemas.

When FALSE, the metaschema for the source and target temp-tables must be the same or the AVM generates a run-time error. The default value is FALSE.

pairs-list

An optional character expression that evaluates to a comma-separated list of the target and source temp-table pairs to be copied. Following is the pairs-list syntax:

```
target-table1, source-table1 [, target-table2, source-table2 ] ...)
```

If specified, the AVM copies only the listed temp-tables by matching the target and source temp-table names.

If not specified, the AVM copies all the temp-tables in the order they were defined or added in the ProDataSets. If either the source or target ProDataSet has one or more extra temp-tables at the end, the extra temp-tables are ignored.

current-only

An optional logical expression where TRUE indicates that the AVM copy only the current record from each temp-table at each level in the source ProDataSet object to the target ProDataSet object. The default value is FALSE.

Note: You might need to synchronize the buffers to ensure they are the related buffers. Once you have read a record into a top-level buffer, you can synchronize the related buffers by calling the SYNCHRONIZE( ) method.

To copy the current record from a single temp-table, you can use the BUFFER-COPY statement or BUFFER-COPY( ) method.

name-prefix

An optional character expression used as the prefix for naming the target ProDataSet. If the parameter is not passed, or is passed as the Unknown value (?), the AVM uses the default "cpy" prefix. If the parameter is passed as an empty string """, then no prefix is added and the target ProDataSet will have the same name as the source.

When the AVM copies the source ProDataSet object, it copies each temp-table in its entirety and in the order in which the temp-table was defined. That is, it does not copy the temp-tables in an interleaved and nested manner based on their data relations. If either the source or target ProDataSet has one or more extra temp-tables at the end, the extra temp-tables are ignored.
When the AVM copies a ProDataSet object in any mode, except loose-copy mode, and the target ProDataSet object has a metaschema (that is, temp-table and relation definitions), the source ProDataSet object metaschema must be the same. If the source and target ProDataSet object metaschema is not the same, the AVM generates a run-time error. If the target ProDataSet object is a newly created dynamic object with only a handle and no metaschema, the AVM copies the source ProDataSet object including its metaschema.

**Note:** If the source or target (but not both) ProDataSet has any before-table records, you can use COPY-DATASET on that ProDataSet. However, if `append mode` or `replace mode` is specified and the target ProDataSet has any before-table records, the AVM generates a run-time error.

**See also:** ATTACH-DATA-SOURCE( ) method, FILL-MODE attribute, COPY-TEMP-TABLE( ) method

---

**COPY-SAX-ATTRIBUTES( ) method**

Performs a deep copy of a SAX-attributes object.

Typically, this method is used to capture the contents of the SAX-attributes object automatically created, populated, and destroyed by the SAX parser during the scope of a call to the startElement callback procedure. For example, to preserve the attributes of an XML element outside of the startElement procedure, you create a SAX-attributes object outside the scope of the startElement callback and use this method on the handle of the new object. The handle to the new SAX-attributes object could then be passed, for example, as a parameter to the START-ELEMENT( ) method of a SAX-writer object. In this way, you can easily program a concurrent SAX read/write routine.

The copy deletes any previous contents of the target handle and replaces them with the contents of the source handle. Remember, if you explicitly create SAX-attributes objects using the CREATE SAX-ATTRIBUTES statement, you must explicitly delete the objects when your copying operations complete.

**Return type:** LOGICAL

**Applies to:** SAX-attributes object handle

**Syntax**

```plaintext
target-handle: COPY-SAX-ATTRIBUTES ( source-handle )
```

- **target-handle**
  A handle to a valid SAX-attributes object. The contents of this SAX-attributes object handle will be overwritten by the contents of the SAX-attributes object of the `source-handle`.

- **source-handle**
  A handle to a valid SAX-attributes object. The contents of this SAX-attributes object will overwrite the contents of the `target-handle` SAX-attributes object.

The following is an example:
COPY-TEMP-TABLE() method

Copies a source temp-table object to a target temp-table object. Either of the temp-tables (source or target) may be a member of a ProDataSet object. The AVM empties the target temp-table of all records before copying the source temp-table, by default.

**Return type:** LOGICAL  
**Applies to:** Temp-table object handle

**Syntax**

```
```

- `targ-tt-handle`  
The handle to the target temp-table object to receive the copy.

- `src-tt-handle`  
The handle to the source temp-table object from which to copy.

- `append-mode`  
An optional logical expression where TRUE indicates that the AVM copy the temp-table object in an append mode.

  When TRUE, the AVM appends the source temp-table object to the target temp-table object. If there is a unique index on the target temp-table and the AVM finds a row with a duplicate key, it does not replace the row. If there is not a unique index on the target temp-table, the AVM appends the data row from the source temp-table to the target temp-table, which might result in duplicate rows. If this operation results in duplicate rows, the AVM does not generate a run-time error.

- `replace-mode`  
When FALSE, the AVM does not append records in the target temp-table object. The default value is FALSE.

  The AVM ignores this expression when `replace-mode` is TRUE.

- `loose-copy-mode`  
When you are certain a temp-table object does not contain duplicate rows, copying the object in append mode is more efficient than copying it in replace mode.

- `name prefix`  
When TRUE, the AVM copies all temp-table objects. If any object has the same name as an existing temp-table object, it replaces it.

**Note:** In this mode, the AVM treats duplicate temp-table rows during the copy operation in the same way it treats duplicate temp-table rows during a fill operation in MERGE mode.
COPY-TEMP-TABLE( ) method

replace-mode

An optional logical expression where TRUE indicates that the AVM copy the temp-table object in a replace mode.

When TRUE, the AVM replaces records in the target temp-table object with corresponding records from the source temp-table object. The target temp-table must have a unique primary index that the AVM can use to find the corresponding record. When the corresponding record is found in the target temp-table, the AVM replaces the target record with the source record. When the corresponding record is not found in the target temp-table, the AVM creates a new target record using the source record. If the before-image table associated with the target temp-table contains a row for the target record, the row is left in place.

Copying a temp-table object in replace mode is less efficient than copying it in append mode. When you are certain a temp-table object does not contain duplicate rows, copy the object in append mode.

When FALSE, the AVM does not replace records in the target temp-table object. The default value is FALSE.

loose-copy-mode

An optional logical expression where TRUE indicates that the AVM copy the temp-table object in a loose-copy mode. That is, it relaxes the requirement that the metaschema for the source and target temp-tables be the same.

When TRUE, the AVM copies the source temp-table object to the target temp-table object based on a field mapping between the source and target temp-table buffers. If there is an attached data source with a field mapping, the AVM uses that field mapping to copy fields from the source temp-table buffer to its target temp-table buffer. If there are fields in either buffer that do not exist in the other, they are ignored. If there is no field mapping with the attached data source, or there is no attached data source, the AVM copies only those fields with the same name that appear in both the source and target temp-table metaschema.

When FALSE, the metaschema for the source and target temp-tables must be the same or the AVM generates a run-time error. The default value is FALSE.

name-prefix

An optional character expression used as the prefix for naming the target temp-table. If the parameter is not passed, or is passed as the Unknown value (?), the AVM uses the default “cpy” prefix. If the parameter is passed as an empty string “”, then no prefix is added and the target temp-table will have the same name as the source.

If the source temp-table object has a before-image table that contains changed row data, the AVM generates a run-time error.

When the AVM copies a temp-table object in any mode, except loose-copy mode, and the target temp-table object is in a PREPARED state (that is, it has a metaschema), the source temp-table object metaschema must be the same. Each column in the source temp-table must match the target temp-table in position, data type, and extent. If the source temp-table object metaschema is not the same, the AVM generates a run-time error. If the target temp-table object is not in a PREPARED state (that is, it has no metaschema), the AVM copies the source temp-table object including its metaschema.
If the target temp-table object is a member of a ProDataSet object, the AVM does not track changes to the data in that temp-table (it ignores the TRACKING-CHANGES attribute setting during the copy operation).

**Note:** If the source or target (but not both) temp-table has any before-table records, you can use COPY-TEMP-TABLE on that temp-table. However, if append mode or replace mode is specified and the target temp-table has any before-table records, the AVM generates a run-time error.

**See also:** FILL-MODE attribute, COPY-DATASET( ) method

### CPCASE attribute

The case table the AVM uses to establish case rules for the Internal Code Page (-cpinternal) startup parameter.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

This attribute reads the value you set using the Case Table (-cpcase) startup parameter.

### CPCOLL attribute

The collation table the AVM uses with the Internal Code Page (-cpinternal) startup parameter.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

By default, the AVM uses the collation rules you specify to compare characters and sort records. The collation rules specified with the Collation Table (-cpcoll) startup parameter take precedence over a collation specified for any database the AVM accesses during the session, except when the AVM uses or modifies pre-existing indexes. If you do not specify a collation with the -cpcoll startup parameter, the AVM uses the language collation rules defined for the first database on the command line. If you do not specify a database on the command line, the AVM uses the collation rules with the default name "basic" (which might or might not exist in the convmap.cp file).

### CPINTERNAL attribute

The internal code page the AVM uses in memory.
CPLOG attribute

The code page for all messages written to the log (.lg) file.

Data type: CHARACTER
Access: Readable
Applies to: SESSION system handle

This attribute reads the value you set using the Log File Code Page (-cplog) startup parameter.

CPPRINT attribute

The code page the AVM uses for the OUTPUT TO PRINTER statement.

Data type: CHARACTER
Access: Readable
Applies to: SESSION system handle

This attribute reads the value you set using the Printer Code Page (-cpprint) startup parameter.

CPRCODEIN attribute

The code page the AVM uses to convert text strings into the text segment.

Data type: CHARACTER
Access: Readable
Applies to: SESSION system handle

This attribute reads the value you set using the R-code In Code Page (-crcodein) startup parameter.

CPRCODEOUT attribute

The code page ABL uses at compile time to convert text strings into the text segment and marks the text segment with the code page name.
CPSTREAM attribute

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

This attribute reads the value you set using the R-code Out Code Page (-cprcodeout) startup parameter.

CPSTREAM attribute

The code page the AVM uses for stream I/O.  
**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

This attribute reads the value you set using the Stream Code Page (-cpstream) startup parameter.

CPTERM attribute

The code page the AVM uses for I/O with character terminals.  
**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

This attribute reads the value you set using the Terminal Code Page (-cpterm) startup parameter.

CRC-VALUE attribute

The cyclic redundancy check (CRC) value for either an r-code file, or a database table corresponding to a buffer object.  
**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer object handle, RCODE-INFO system handle

When applied to the RCODE-INFO system handle, the r-code CRC is calculated using the filename and contents of the r-code file specified by the RCODE-INFO:FILE-NAME attribute.

When applied to the Buffer object handle, the database CRC is calculated using the metaschema _CRC field value from the _File record for the database record corresponding to the buffer object's table (which can be a standard or temp-table).
The CRC for a temp-table is calculated differently than for a standard table. Some differences include:

- Standard tables have a _File record in the database that contains a _CRC field for the CRC value, which is calculated as you make changes to the table. Temp-tables do not have a _File record, and do not exist in a database.
- The CRC values for both standard and temp-tables include the data type, extent and position of each column in the table, as well as index information. However, the CRC value for a standard table includes additional information that a CRC value for a temp-table does not (such as, the _Order field in the _File record).
- The CRC value for a standard table is stored in a .r file. The AVM uses that CRC value at run time to verify the integrity of application r-code that uses the table. The AVM uses the CRC value for a temp-table to compare table parameters between a calling and called procedure (to avoid a field-by-field comparison).

For more information on CRCs, see *OpenEdge Deployment: Managing ABL Applications.*

---

**CREATE-LIKE() method**

Creates a table like another existing table, or a dynamic ProDataSet object like another static or dynamic ProDataSet object.

**Return type:** LOGICAL

**Applies to:** ProDataSet object handle, Temp-table object handle

**Syntax**

```
CREATE-LIKE( { src-buffer-handle-exp | src-table-name-exp } [
    , src-index-name-exp ] )
```

```
CREATE-LIKE( { src-dataset-handle | src-dataset-name } [
    , name-prefix ] )
```

*src-buffer-handle-exp*

An expression that evaluates to a buffer handle from which to copy the field definitions, and optionally, the indexes if *src-index-name-exp* is not specified.

*src-table-name-exp*

An expression that evaluates to a table name from which to copy the field definitions and, optionally, the indexes if *src-index-name-exp* is not specified.

*src-index-name-exp*

A character expression giving an index to be copied from the source table. If this option is specified, only this single index is copied from the source table.
**CREATE-LIKE-SEQUENTIAL( ) method**

*src-dataset-handle*

The handle to the ProDataSet object from which to create the new ProDataSet object.

*src-dataset-name*

The name of the ProDataSet object from which to create the new ProDataSet object.

*name-prefix*

A character expression to prepend to each of the source ProDataSet member buffer names, which creates a new name for each new member buffer.

For a table handle, this method copies the field definitions from the specified source table and establishes the default or specified source indexes. You cannot call this method after another definitional method is called unless you call CLEAR( ) first.

For a ProDataSet object handle, this method creates a dynamic ProDataSet object like another static or dynamic ProDataSet object. The AVM creates the new ProDataSet object with the same name, temp-table definitions, and relation definitions. The AVM also creates the same before-image and after-image tables, if any exist for the source object. No data from the source temp-tables is copied. The AVM also lets you rename the newly created ProDataSet member buffers by prepending a prefix to the source buffer names.

See also: CREATE-LIKE-SEQUENTIAL( ) method

---

**CREATE-LIKE-SEQUENTIAL( ) method**

Creates a table like another existing database table or temp-table. Unlike CREATE-LIKE( ), which creates temp-table fields in metaschema _field._field-rpos order (POSITION order in the .df schema definition file) of the source table’s fields, this method creates fields in _field._order sequence.

**Return type:** LOGICAL

**Applies to:** Temp-table object handle

You can guarantee agreement of temp-table field order between any client and any AppServer using CREATE-LIKE-SEQUENTIAL( ), as long as the _field._order values are the same. CREATE-LIKE-SEQUENTIAL( ) uses the field order as defined in the Data Dictionary when the source is a database table.

**Syntax**

```
CREATE-LIKE-SEQUENTIAL( { src-buffer-handle-exp | src-table-name-exp } [, src-index-name-exp ] )
```

*src-buffer-handle-exp*

An expression that evaluates to a buffer handle from which to copy the field definitions, and optionally, the indexes if src-index-name-exp is not specified.
**CREATE-NODE( ) method**

Create an XML node in the current document. The first parameter must be a valid X-noderef handle and will refer to the new XML node if the method succeeds. This method merely creates the XML node as part of the XML document. The INSERT-BEFORE or APPEND-CHILD methods are required to actually insert it into the document’s tree.

**Return type:** LOGICAL

**Applies to:** X-document object handle

**Syntax**

```
CREATE-NODE( x-node-handle , name , type )
```

**x-node-handle**

A valid X-noderef handle to use for the new XML node.

**name**

A character expression representing the NAME of the node. The relationship between the node NAME and SUBTYPE attributes is shown in Table 75.

**type**

A character expression representing the node’s SUBTYPE, which will be one of: ATTRIBUTE, CDATA-SECTION, COMMENT, DOCUMENT-FRAGMENT, ELEMENT, ENTITY-REFERENCE, PROCESSING-INSTRUCTION, TEXT.
The following example demonstrates creating a node in a document. If hDoc is an X-document handle, and hNoderef and hNoderefChild are X-noderefs, this is how you would add hNoderefChild to hNoderef in the document associated with hDoc:

```abl
/* Assume hNoderef has previously been added to the tree. Create an ABL handle that can refer to a node in an XML parse tree. */
CREATE X-NODEREF hNoderefChild.

/* Create an XML node whose name is "Address" & whose type is "ELEMENT" */
hDoc:CREATE-NODE(hNoderefChild, "Address", "ELEMENT")

/* Put this child into the tree and ultimately into the document. */
hNoderef:APPEND-CHILD(hNoderefChild).
```

### CREATE-NODE-NAMESPACE( ) method

Creates a namespace-aware XML node whose name can be either a single string \( y \) or an \( x:y \) combination.

**Note:** To ensure consistency across all nodes in an XML document, use either the CREATE-NODE-NAMESPACE( ) method or the CREATE-NODE( ) method to build an XML document; do not use both methods within a single document.

**Return type:** LOGICAL

**Applies to:** X-document object handle

**Syntax**

```abl
CREATE-NODE-NAMESPACE
( x-node-handle , namespace-uri , qualified-name , type )
```

* x-node-handle

A valid X-noderef handle to use for the new namespace-aware XML node.
namespace-uri

A character expression representing the namespace Uniform Resource Identifier (URI). The *namespace-uri* must be unique and persistent. Although the *namespace-uri* may be an HTTP URL, there is no guarantee that it points to a retrievable resource. It is only a name and care should be taken if you use this name for other purposes.

If the character expression evaluates to either the empty string ("") or the Unknown value (?), no namespace is associated with the element.

qualified-name

A character expression representing the name of the node, optionally qualified with a prefix including a colon (for example, *prefix:node-name*). Unless you are using a default namespace, a prefix is required and should be set to the prefix specified when you declared the namespace using the xmlns attribute.

type

A character expression representing the node’s SUBTYPE, which will be either ELEMENT or ATTRIBUTE.

The following code fragment illustrates how to create a namespace-aware node in an XML document using either a specific namespace or the default namespace:

```c
/* Look for a colonized name in rootNodeName. */
found = INDEX(rootNodeName, ":").
IF found > 0 THEN DO:
  /* Namespace declarations are special kinds of attributes that belong in the http://www.w3.org/2000/xmlns/ namespace. */
  errStat = hDocument:CREATE-NODE-NAMESPACE(hNsDecl, "http://www.w3.org/2000/xmlns/", "xmlns:" + SUBSTRING(rootNodeName, 1, found - 1), "attribute").
END.
ELSE DO:
  /* Use the default namespace, which does not need a namespace declaration prefix, and assign it to the http://www.w3.org/2000/xmlns/ namespace. */
END.
IF NOT errStat THEN LEAVE.
/* Set the value of the namespace attribute to the namespace URI. */
hNsDecl:NODE-VALUE = namespaceURI.
```

**CREATE-RESULT-LIST-ENTRY( ) method**

Creates an entry in the result list for the current row. The developer uses the *CREATE-RESULT-LIST-ENTRY* method in conjunction with new browse rows or new query rows to synchronize the data with the query.
**CURRENT-CHANGED attribute**

Indicates whether a record in a buffer is different following a FIND CURRENT or GET CURRENT statement or method. If the record is different, CURRENT-CHANGED is TRUE. Otherwise, CURRENT-CHANGED is FALSE.

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** Buffer object handle

**Note:** The CURRENT-CHANGED attribute corresponds to the CURRENT-CHANGED function.

**CURRENT-COLUMN attribute**

The value of the browse column that contains the current cell. This attribute moves focus to the cell in the specified column in the current row.

**Data type:** HANDLE

**Access:** Readable/Writeable

**Applies to:** BROWSE widget

For the browse, if the browse or a browse component currently has focus, then setting the attribute to another column causes the proper LEAVE and cell ENTRY events to happen.

If the setting of the CURRENT-COLUMN attribute happens when focus is outside of the browse, then the browse’s internal handle to the current column is updated so that it will become the current column when you tab back into the browse. Also if you apply "START-SEARCH" the search mode will now use this column to search on.

**CURRENT-ENVIRONMENT attribute**

Returns a list of CGI environment variable settings and HTTP header information, and is used by the `get-cgi` WebSpeed API function. Intended for internal use only.
CURRENT-ITERATION attribute (data objects)

Indicates which iteration level corresponds to the buffer handle during a recursive FILL of a ProDataSet.

Data type: INTEGER
Access: Readable
Applies to: Buffer object handle

As a recursive ProDataSet FILL is proceeding, it creates clones of the relevant buffers, relations, queries and data-sources for each level of recursion. As a new record is added to the ProDataSet, it fires FILL events on the recursed, cloned buffer. From inside the event handler, you may want to see previous iterations of the buffer; its parent, grandparent, great-grandparent, and so on. CURRENT-ITERATION returns the level of iteration for the cloned buffer handle.

If the buffer object handle does not point to a ProDataSet temp-table or is not part of a recursive data-relation, CURRENT-ITERATION returns the Unknown value (?)

See also: DEFINE DATASET statement, FILL( ) method, GET-ITERATION( ) method (data objects), NUM-ITERATIONS attribute (data objects), RECURSIVE attribute

CURRENT-ITERATION attribute (widget objects)

A handle for the current iteration of the frame or dialog box.

Data type: HANDLE
Access: Readable/Writeable
Applies to: DIALOG-BOX widget, FRAME widget

This attribute is a read-only attribute for dialog boxes.

CURRENT-QUERY( ) method

The handle to the ProDataSet query that contains the currently selected row in the ProBindingSource. This method enables access to the correct child query when a bound .NET grid edits, creates, or deletes a row from a child table.

Use this method when the .NET control is bound to a ProDataSet object that contains child buffers.

1389
**CURRENT-QUERY() method**

**Data type:** HANDLE

**Access:** Readable

**Applies to:** Data-relation object handle

**Syntax**

```
CURRENT-QUERY( [ INPUT band-index AS INTEGER ] )
```

**band-index**

An optional INTEGER value that specifies the band index in a hierarchical grid. The band index is a 0-based index. Use this parameter only with recursive data-relations. If you specify this parameter for a non-recursive data-relation, the AVM raises an error.

When a .NET control binds to a ProBindingSource that uses a ProDataSet as its data source object, multiple relations for the same parent-child relationship might be presented to the user simultaneously. When the user first expands a parent row in the bound .NET control, the ProBindingSource creates a new child query and displays all child rows for that parent row. The ProBindingSource uses the ProDataSet object’s data-relation query to create and maintain this unique query for all child rows related to the expanded parent row.

**Note:** You cannot set this query handle or modify the query.

The following code fragment shows an event handler. The event handler accepts information from a bound UltraWinGrid displaying Order and Orderline data through the grid’s extended version of the .NET System.EventArgs class. From that information, the event handler can find the correct query for the currently selected record.

```
DEFINE VARIABLE hDataSet AS HANDLE NO-UNDO.
...
PROCEDURE BeforeRowUpdate:
    DEFINE INPUT PARAMETER sender AS System.Object  NO-UNDO.
    DEFINE INPUT PARAMETER args AS Infragistics.Win.UltraWinGrid.CancelableRowEventArgs NO-UNDO.
    DEFINE VARIABLE cBufferName AS CHARACTER NO-UNDO.
    DEFINE VARIABLE hRelation AS HANDLE NO-UNDO.
    DEFINE VARIABLE hQuery AS HANDLE NO-UNDO.
    cBufferName = args:Row:Band:Key.
    IF cBufferName EQ "ttOrder" THEN
        ASSIGN
            hRelation = hDataSet:GET-RELATION(1)
            hQuery  = hRelation:CURRENT-QUERY.
        END.
    ELSE IF cBufferName EQ "ttOrderLine" THEN
        ASSIGN
            hRelation = hDataSet:GET-RELATION(2)
            hQuery  = hRelation:CURRENT-QUERY.
        END.
    END.
END PROCEDURE.
```
When a ProBindingSource is attached to a ProDataSet with a recursive data-relation, the code above does not work because a single buffer is associated with multiple BandIndexes in a hierarchical grid. The event handler must specify the BandIndex of the current row to determine the correct query.

The following example shows a similar event handler using the optional parameter. Because an employee might also be a manager and have employees of his own, dsRecursive has a recursive data-relation between EmpName and Manager. For the top band of the hierarchy, the event handler can use the TOP-NAV-QUERY. For lower bands, it needs the optional parameter to determine the correct query.

```
DEFINE TEMP-TABLE ttEmp NO-UNDO
BEFORE-TABLE ttEmpB
FIELD EmpName AS CHARACTER
FIELD Manager AS CHARACTER
FIELD HireDate AS INTEGER
INDEX idxEmpName AS UNIQUE EmpName.

DEFINE DATASET dsRecursive FOR ttEmp
DATA-RELATION r1 FOR tttemp, tttemp
RELATION-FIELDS(EmpName,Manager) RECURSIVE.

DEFINE VARIABLE hRelation AS HANDLE NO-UNDO.
DEFINE VARIABLE hTopQuery AS HANDLE NO-UNDO.

...

PROCEDURE BeforeRowUpdate:
  DEFINE INPUT PARAMETER sender AS System.Object NO-UNDO.
  DEFINE INPUT PARAMETER args AS Infragistics.Win.UltraWinGrid.CancelableRowEventArgs NO-UNDO.
  DEFINE VARIABLE bandIndex AS INTEGER NO-UNDO.
  DEFINE VARIABLE hQuery AS HANDLE NO-UNDO.
  ASSIGN
    bandIndex = args:Row:Band:Index
    hRelation = DATASET dsRecursive:GET-RELATION(1).
  IF bandIndex EQ 0 THEN
    hQuery = hTopQuery.
  ELSE IF bandIndex > 0 THEN
    hQuery = hRelation:CURRENT-QUERY(bandIndex).
  END PROCEDURE.
```

See also: BandIndex property

---

**CURRENT-RESULT-ROW attribute**

The sequence number of the current row of a dynamic query’s result list.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** Query object handle

**Note:** The CURRENT-RESULT-ROW attribute corresponds to the CURRENT-RESULT-ROW function.
CURRENT-ROW-MODIFIED attribute

Indicates whether any cells in the current row have been changed.

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** BROWSE widget

The CURRENT-ROW-MODIFIED attribute is set to TRUE if the user has modified any cell within the current row since focus moved to that row.

CURRENT-WINDOW attribute

A current window for the specified procedure.

**Data type:** HANDLE

**Access:** Readable/Writeable

**Applies to:** Procedure object handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

Specifies and allows you to reset the current window used to parent alert box, dialog box, or frame widgets for the specified procedure. The default value is the Unknown value (?). Returns the Unknown value (?) for a Web service procedure or proxy persistent procedure.

If you set this attribute to the handle of a window, this value takes precedence over the CURRENT-WINDOW handle to provide the default window for parenting alert boxes, frames, and dialog boxes created within the procedure.

This attribute is especially useful for creating and associating a unique current window with each instantiation of a persistent procedure. For more information on persistent procedures, see the RUN statement reference entry.

CURSOR-CHAR attribute

The current character position of the text cursor on the current text line in an editor widget.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** EDITOR widget

Assigning a value to CURSOR-CHAR moves the text cursor to the specified character position on the current text line. If the editor widget is not already realized, the AVM realizes the widget when you query the CURSOR-CHAR attribute.
The line within an editor widget where the text cursor is positioned.

Data type: INTEGER
Access: Readable/Writeable
Applies to: EDITOR widget

Assigning a value to CURSOR-LINE moves the text cursor to the specified line. If the editor widget is not already realized, the AVM realizes the widget when you query the CURSOR-LINE attribute.

The character offset of the cursor within a widget.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget

Assigning a value to CURSOR-OFFSET moves the text cursor to the specified character offset. If the editor widget is not already realized, the AVM realizes the widget when you query the CURSOR-OFFSET attribute.

In Windows, both the regular editor and the large editor support CURSOR-OFFSET.

For browses, this attribute applies only to fill-in and combo-box browse columns.

For browse columns, CURSOR-OFFSET specifies the character offset of the cursor within a browse-cell of the browse column.

The behavior of the RETURN key for the fill-in widgets of a frame.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: SESSION system handle

If TRUE, the RETURN key in a fill-in acts like a TAB, and if the fill-in is the last widget in the tab order of its parent frame and of all ancestor frames, the RETURN key applies a GO event to the frame (behavior prior to Version 7). This GO event, from a fill-in RETURN, propagates to all ancestor frames and their descendants, including siblings of the current frame and their descendants, all in the same frame family. If a widget is not a fill-in, the window system handles RETURN entries.
DATA-SOURCE attribute

The default value is TRUE for character interfaces and FALSE for graphical interfaces. The AVM ignores this attribute if there is a default button on the frame.

DATA-SOURCE attribute

Returns the handle to the Data-source object currently attached to the ProDataSet object buffer.

Data type: HANDLE
Access: Readable
Applies to: Buffer object handle

DATA-SOURCE-COMPLETE-MAP attribute

Returns a comma-separated list of field name pairs for all fields in a ProDataSet temp-table buffer that are mapped to corresponding fields in an attached Data-source object.

Data type: CHARACTER
Access: Readable
Applies to: Buffer object handle

This list is formatted as a comma-separated list of field name pairs, qualified with the ProDataSet and Data-source temp-table names, using the following syntax:

Syntax

```
 tt-buffer-name.tt-field-name,db-table-name.db-field-name [, ...]
```

Note: You may use a subscript reference for array fields mapped explicitly through subscripts.

If the ProDataSet temp-table buffer does not have an attached Data-source object, this attribute returns the Unknown value (?).

Use the ATTACHED-PAIRLIST attribute to get a list of only the field name pairs you specified with the most recently attached Data-source object.

DATA-SOURCE-MODIFIED attribute

Indicates that data in the data source associated with a ProDataSet temp-table buffer has been modified.
DATA-SOURCE-ROWID attribute

Identifies the data-source row corresponding to the buffer object handle.

**Data type:** ROWID  
**Access:** Readable/Writeable  
**Applies to:** Buffer object handle

This attribute locates the data-source row corresponding to either an after-table buffer or a before-table buffer. The portion of the SAVE-ROW-CHANGES( ) method that locates the appropriate data-source row is used to produce a ROWID for users who want to either make their own version of SAVE-ROW-CHANGES( ) or access the source record in some way before or after SAVE-ROW-CHANGES( ).

**Syntax**

```
DATA-SOURCE-ROWID( { join level | buffer name } )
```

- **join level**
  - An integer expression that evaluates to the level of join, if the data-source is a join.

- **buffer name**
  - A character expression that evaluates to the name of one of the data-source buffers.

**See also:**  
AFTER-TABLE attribute, BEFORE-TABLE attribute,  
SAVE-ROW-CHANGES( ) method

DATA-TYPE attribute

A character value that represents the data type of the field associated with the widget. For example, the DATA-TYPE attribute of a slider widget always returns the value "INTEGER" because slider widgets can only represent integer values.
**DATASET attribute**

*Data type:* CHARACTER  
*Access:* Readable/Writeable  
*Applies to:* BROWSE widget (column), Buffer-field object handle, COMBO-BOX widget, EDITOR widget, FILL-IN widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

This attribute is writeable for combo-boxes (only before realization), fill-ins, and text widgets only. For combo-boxes, writing to this attribute makes the drop-down list empty.

You must define this attribute as “CHARACTER” for SIMPLE and DROP-DOWN combo-boxes.

For widgets like image or rectangle, where a data type has no meaning, the attribute returns "UNKNOWN".

The DATA-TYPE attribute is only writable for dynamic fill-ins before they are realized. This attribute is read only for static fill-ins.

---

**DATASET attribute**

Returns the handle for the ProDataSet object of which the buffer is a member. Use this handle to access the attributes and methods of the associated ProDataSet object.

*Data type:* HANDLE  
*Access:* Readable  
*Applies to:* Buffer object handle

---

**DATE-FORMAT attribute**

The format used to represent dates during the current ABL session (for the DATE, DATETIME, and DATETIME-TZ data types).

*Data type:* CHARACTER  
*Access:* Readable/Writeable  
*Applies to:* SESSION system handle

Typical values are "mdy" or "dmy". This attribute provides the same functionality as the Date Format (-d) parameter.

---

**DB-CONTEXT attribute**

Returns the logical database to which the DSLOG-MANAGER system handle currently applies. Valid values are any valid, connected logical name or alias for a database of a supported database type. The default value is the Unknown value (?). If you set DB-CONTEXT to an alias, it returns the logical name of the database currently assigned to that alias.
Each DataServer connection is a separate entity for which you can specify different logging settings. You use this attribute at run time to specify the DataServer connection with which you are working. You must set DB-CONTEXT before accessing any other attribute or method of the DSLOG-MANAGER system handle.

If you set DB-CONTEXT to the Unknown value (?), you cannot access DSLOG-MANAGER until you reset DB-CONTEXT to a valid logical database name or alias. When the database specified in DB-CONTEXT is disconnected, the client automatically sets DB-CONTEXT to the Unknown value (?).

The following statements show how you can set this attribute:

```sql
DSLOG-MANAGER:DB-CONTEXT = "mymss".
DSLOG-MANAGER:DB-CONTEXT = myvar.
DSLOG-MANAGER:DB-CONTEXT = "myalias".
```

---

**DB-REFERENCES attribute**

A comma-separated list of the databases, (in the form of logical database names) referenced by an r-code file or by a persistent procedure. Returns the Unknown value (?) for a Web service procedure or proxy persistent procedure.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** Procedure object handle, RCODE-INFO system handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

The following example displays a list of all databases referenced by sample.r in a comma-separated list that is contained in the DB-REFERENCES attribute.

```sql
RCODE-INFO:FILE-NAME = "sample.r".
DISPLAY RCODE-INFO:DB-REFERENCES.
```

---

**DBNAME attribute**

The logical name of the database from which the field is taken.
**DCOLOR attribute**

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** BROWSE widget (column), Buffer object handle, Buffer-field object handle, COMBO-BOX widget, EDITOR widget, FILL-IN widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

The default logical name for a database name is the name of the database file without the file extension. You can set the logical name of a database using the Logical Database Name (-ld) parameter.

---

**DCOLOR attribute**  
*(Character Interfaces only)*

The color number for the display color of the widget in character mode. This attribute is ignored in graphical interfaces.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (browse, column, and cell), BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, LITERAL widget, MENU widget, MENU-ITEM widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

For browse widgets, it is readable only. For a browse cell, it specifies the color of a specific cell in the view port. You can set this color only as the cell appears in the view port during a ROW-DISPLAY event.

For rectangles, DCOLOR specifies the fill color. In windows, DCOLOR specifies the color inherited by the menu bar, if the menu bar has no color specified.

The color number represents an entry in the color table maintained by the COLOR-TABLE handle.

You can now change the color of the background of menu frames (including menubars, submenus and pop-up menus) using the DCOLOR attribute. Previously, specifying the DCOLOR attribute for menus only changed the default color for menu items. Now, the DCOLOR attribute will be applied to the menu frame also. Note that no syntax changes were made. You can still specify the DCOLOR attribute for individual menu items.

For more information on widget color, see the PFCOLOR attribute.
DDE-ERROR attribute  
(Windows only)

The error condition returned by the most recent exchange in a DDE conversation associated with the frame. A DDE function or a DDE-NOTIFY event initiates an exchange in a DDE conversation.

This attribute is supported only for backward compatibility. Use the Component Object Model (COM) instead.

Data type: INTEGER  
Access: Readable  
Applies to: FRAME widget

Table 76 lists the possible errors returned by an exchange in a DDE conversation.

Table 76: ABL DDE errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>DDE INITIATE failure</td>
</tr>
<tr>
<td>2</td>
<td>A DDE statement (DDE ADVISE, DDE EXECUTE, DDE GET, DDE REQUEST, or DDE SEND) time out</td>
</tr>
<tr>
<td>3</td>
<td>Memory allocation error</td>
</tr>
<tr>
<td>4</td>
<td>Invalid channel number (not an open conversation)</td>
</tr>
<tr>
<td>5</td>
<td>Invalid data item (in topic)</td>
</tr>
<tr>
<td>6</td>
<td>DDE ADVISE failure (data link not accepted)</td>
</tr>
<tr>
<td>7</td>
<td>DDE EXECUTE failure (commands not accepted)</td>
</tr>
<tr>
<td>8</td>
<td>DDE GET failure (data not available)</td>
</tr>
<tr>
<td>9</td>
<td>DDE SEND failure (data not accepted)</td>
</tr>
<tr>
<td>10</td>
<td>DDE REQUEST failure (data not available)</td>
</tr>
<tr>
<td>11</td>
<td>DDE-NOTIFY event failure (data not available)</td>
</tr>
<tr>
<td>99</td>
<td>Internal error (unknown)</td>
</tr>
</tbody>
</table>

This attribute applies to any frame in Windows that is a Dynamic Data Exchange (DDE) frame for a DDE conversation.

DDE-ID attribute  
(Windows only)

The DDE channel number of the most recent conversation involved in an exchange.
DDE-ITEM attribute

This attribute is supported only for backward compatibility. Use the Component Object Model (COM) instead.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** FRAME widget

This attribute applies to any frame in Windows that is a Dynamic Data Exchange (DDE) frame for a DDE conversation.

---

DDE-ITEM attribute  
(Windows only)

The name of the data item affected by the most recent conversational exchange (for example, the name of a worksheet cell such as "R3C5").

This attribute is supported only for backward compatibility. Use the Component Object Model (COM) instead.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** FRAME widget

This attribute applies to any frame in Windows that is a Dynamic Data Exchange (DDE) frame for a DDE conversation.

---

DDE-NAME attribute  
(Windows only)

The name of the application involved in the most recent conversational exchange (for example, the name of a worksheet application such as "EXCEL").

This attribute is supported only for backward compatibility. Use the Component Object Model (COM) instead.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** FRAME widget

This attribute applies to any frame in Windows that is a Dynamic Data Exchange (DDE) frame for a DDE conversation.

---

DDE-TOPIC attribute  
(Windows only)

The topic name of the most recent conversation (for example, the "System" topic, or the name of an Excel worksheet such as "Sheet1").
This attribute is supported only for backward compatibility. Use the Component Object Model (COM) instead.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** FRAME widget

This attribute applies to any frame in Windows that is a Dynamic Data Exchange (DDE) frame for a DDE conversation.

### DEBLANK attribute

How to process leading blanks in fill-in widgets during user input.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** FILL-IN widget

This attribute applies to fill-ins for CHARACTER fields that are enabled for input.

If the DEBLANK attribute is TRUE, the AVM removes leading blanks from the widget following user input that changes the SCREEN-VALUE attribute of the widget. Any leading blanks in the SCREEN-VALUE before input are not removed unless the user modifies the field. After the field is modified, the procedure must explicitly redisplay the field to view the effect of the DEBLANK attribute.

### DEBUG( ) method

Starts and initializes the Debugger, and immediately gives control to the Debugger in stand-alone mode while blocking the invoking procedure.

**Return type:** LOGICAL  
**Applies to:** DEBUGGER system handle

**Syntax**

```
DEBUG ( )
```

This method has the same effect as starting OpenEdge with the Debugger (-debug) startup parameter, except that instead of running the Debugger from the OpenEdge command line, it runs it from the invoking procedure. The invoking procedure then waits to continue execution until the Debugger exits. Although the Debugger has no control over the invoking procedure, it can control any other procedure started with the Debugger RUN option.

If the Debugger starts successfully, this method returns TRUE after the Debugger exits. Otherwise, it returns FALSE with no effect.
DEBUG-ALERT attribute

Indicates whether the AVM provides access to ABL stack trace and .NET stack trace information, when applicable, when an error occurs during a session (TRUE or FALSE). Its major use is for error alert boxes, so you can determine where an error has occurred in your code.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: SESSION system handle

You can also set DEBUG-ALERT to TRUE using the Debug Alert (-debugalert) startup parameter. For more information about the -debugalert startup parameter, see OpenEdge Deployment: Startup Command and Parameter Reference.

When an unhandled ABL error or .NET Exception occurs—in an interactive session for any ABL client the AVM displays an Error message box. When Debug Alert is TRUE, the message box also includes a Help button. Clicking on the Help button produces a Stack Trace dialog box containing ABL stack trace and .NET stack trace information. The ABL stack trace and the .NET stack trace are written to the client log when the Client Logging (-clientlog) startup parameter is specified. The top of the stack (most recent call) is displayed at the top of the trace listing.

For more information about debugging from an alert dialog box, see OpenEdge Development: Debugging and Troubleshooting.

DECIMALS attribute

Indicates the number of decimal places, after the decimal point, that are stored for a buffer-field object that corresponds to a DECIMAL field. If the value of DECIMALS is nonzero, the AVM rounds off any source that you assign to BUFFER-VALUE to the specified number of decimal places before completing the assignment. Otherwise, the assignment executes without rounding off the source value.

Valid values are zero (0) to ten (10).

The attribute also applies to temp-table buffer fields. If the WRITE-XML() method is used on the object containing the buffer field, then the XML Document generated will write the decimal field with the number of decimal places specified.

Note: The AVM determines the number of decimal places to display, as opposed to store, from the FORMAT attribute (not the DECIMALS attribute) of the buffer-field.
DECLARE-NAMESPACE( ) method

Adds a namespace declaration to a tag in the XML document represented by a SAX-writer object.

Return type: LOGICAL
Applies to: SAX-writer object handle

Syntax

DECLARE-NAMESPACE( namespace-URI [ , prefix ] )

namespace-URI

A CHARACTER or LONGCHAR expression evaluating to the URI of the attribute.

prefix

A CHARACTER or LONGCHAR expression evaluating to the prefix of the namespace.

Call this method to add a namespace declaration to a start tag. You can only call this method directly following a call to START-ELEMENT, WRITE-EMPTY-ELEMENT, INSERT-ATTRIBUTE, or DECLARE-NAMESPACE method. That is, you can only call this method when the WRITE-STATUS attribute is SAX-WRITE-TAG. The WRITE-STATUS attribute remains SAX-WRITE-TAG after this method call.

Regardless of the value of the STRICT attribute, this method fails if you do not call it after one of the valid methods listed above.

If you use an empty string ("") or the Unknown value (?) for the prefix, or you omit the prefix, then the method declares the default namespace: xmlns="namespace-URI".

DEFAULT attribute

Indicates whether the button is a default button.
DEFAULT-BUFFER-HANDLE attribute

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BUTTON widget

If the DEFAULT attribute is TRUE, the specified button is a default button. To make the specified button the default button for the frame, you must also set the frame’s DEFAULT-BUTTON attribute to the handle of the button. A default button is one that handles all RETURN events when no other RETURN-enabling widget in the frame or dialog box has focus. RETURN-enabling widgets include any field-level widget for which a RETURN trigger is defined, or any button, whether or not it has a trigger defined. Thus, if a button has focus, that button handles the next RETURN event. If any other field-level widget without a RETURN trigger has focus, the default button handles the next RETURN event.

You can set this attribute only before the widget is realized.

Note: When the frame receives a default RETURN event, it actually sends a CHOOSE event to the default button. If the user presses the RETURN key while in a frame that has no default button, and the frame is part of a frame family, the AVM applies the CHOOSE event to the first default button it can find within the frame family in random order.

DEFAULT-BUFFER-HANDLE attribute

Like static temp-tables, every dynamic temp-table is created with at least one buffer. This buffer’s object handle is returned by this attribute. DEFAULT-BUFFER-HANDLE cannot be called until the TEMP-TABLE-PREPARE() method has been called, since the default buffer is not created until then.

Data type: HANDLE
Access: Readable
Applies to: Temp-table object handle

Syntax

\[ tt-buffer-handle = tt-handle:DEFAULT-BUFFER-HANDLE \]

DEFAULT-BUTTON attribute

Indicates whether a button is a default button for the frame or dialog box.

Data type: HANDLE
Access: Readable/Writeable
Applies to: DIALOG-BOX widget, FRAME widget

To make the specified button the default button for the frame or dialog box, you must also set the button’s DEFAULT attribute to TRUE.

The DEFAULT-BUTTON attribute for frames is not supported in character mode.
The default button cannot display an image.

A default button is one that handles all RETURN events when no other RETURN-enabling widget in the frame or dialog box has focus. RETURN-enabling widgets include any field-level widget for which a RETURN trigger is defined, or any button, whether or not it has a trigger defined. Thus, if a button has focus, that button handles the next RETURN event. If any other field-level widget without a RETURN trigger has focus, the default button handles the next RETURN event.

**Note:** When the frame receives a default RETURN event, it actually sends a CHOOSE event to the default button. If the user presses the RETURN key while in a frame that has no default button, and the frame is part of a frame family, the AVM applies the CHOOSE event to the first default button it can find within the frame family in random order.

---

**DEFAULT-COMMIT attribute**  
(AppServer only)

Indicates how an open transaction under the control of a transaction initiating procedure is to complete if the procedure is deleted in the absence of any SET-COMMIT( ) method or SET-ROLLBACK( ) method.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Transaction object handle

Setting the DEFAULT-COMMIT attribute to TRUE ensures that the transaction is completed. Setting it to FALSE ensures that the transaction is rolled back. The default value is FALSE.

**Note:** One common event that can terminate an open transaction is deleting the transaction initiating procedure that created the transaction.

---

**DEFAULT-STRING attribute**

The unformatted version of the INITIAL attribute.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Buffer-field object handle

For example, consider the following temp-table definition:

```plaintext
DEFINE TEMP-TABLE ttFoo
  FIELD dFoo AS DATE  INITIAL TODAY
  FIELD iFoo AS INTEGER  INITIAL 5000.
```
The DEFINE TEMP-TABLE statement defines the DATE field ttFoo.dFoo with an INITIAL value of TODAY. For this field, the INITIAL attribute is [today’s date], formatted subject to SESSION:DATE-FORMAT. However, the DEFAULT-STRING attribute contains TODAY, the unformatted character value.

The INTEGER field ttFoo.iFoo is defined with an INITIAL value of 5000. The INITIAL attribute is the formatted 5,000. The DEFAULT-STRING attribute contains the unformatted 5000.

DEFAULT-STRING renders its dates and numeric values in LOCAL format, subject to the DATE-FORMAT and NUMERIC-FORMAT attributes of the SESSION system handle.

See also: DATE-FORMAT attribute, DEFAULT-VALUE attribute, INITIAL attribute, NUMERIC-FORMAT attribute

DEFAULT-VALUE attribute

The initial value of a table column in the native data type of the buffer-field.

Data type: The data type of the corresponding buffer-field
Access: Readable
Applies to: Buffer-field object handle

For a DATE field with an INITIAL value of TODAY, DEFAULT-VALUE would contain a DATE value with today’s date. For a DATETIME field with an INITIAL value of NOW, DEFAULT-VALUE would contain a DATETIME value with the current time. For a DECIMAL field, DEFAULT-VALUE would contain a DECIMAL value, as opposed to the INITIAL attribute, which has a CHARACTER data type.

DEFAULT-VALUE is suitable for assignment into a newly created record, but not as the initial value in the ADD-NEW-FIELD( ) method. In this case, TODAY and NOW will be the values and not the special strings for TODAY and NOW. That is, DEFAULT-VALUE for the initial argument in ADD-NEW-FIELD( ) will return INITIAL [today’s date], instead of INITIAL TODAY.

In order for ADD-NEW-FIELD( ) to work correctly with an existing buffer for a new temp-table being dynamically built, you can use the ADD-LIKE-FIELD( ) method or, rather than using DEFAULT-VALUE, you can use the DEFAULT-STRING attribute, which is the unformatted, character data type version of the DEFAULT-VALUE including TODAY and NOW.

See also: ADD-LIKE-FIELD( ) method, ADD-NEW-FIELD( ) method, DATE-FORMAT attribute, DEFAULT-STRING attribute, INITIAL attribute, NUMERIC-FORMAT attribute

DELETE( ) method

Deletes an item from a combo box, radio-set, or selection list.
**DELETE( ) method**

**Return type:** LOGICAL

**Applies to:** BROWSE widget (column), COMBO-BOX widget, RADIO-SET widget, SELECTION-LIST widget

This is the syntax for a combo-box, selection-list, or browse column.

**Syntax (combo-box, selection-list, or browse column)**

```plaintext
DELETE ( list-index | list-item )
```

**list-index**
- An integer expression that specifies the ordinal position of a value in the combo box list or selection list.

**list-item**
- A character-string expression that specifies a single value or a delimiter-separated list of values in the widget.

The DELETE( ) method removes the item specified by list-index, or removes the specified list-item from the list. list-item can represent multiple items. For example, you might specify DELETE( "Chicago, Boston, New York" ), where the delimiter is a comma. The delimiter is a comma by default or is specified by the DELIMITER attribute. If the method is successful, it returns TRUE.

For browses, this method applies only to combo-box browse columns.

This is the syntax for a radio-set.

**Syntax (radio-set)**

```plaintext
DELETE ( label )
```

**label**
- A character-string expression that specifies an item to delete from the radio-set.

The DELETE( ) method deletes the item from the radio-set, whose appearance changes depending on the user interface and the setting of the AUTO-RESIZE attribute. For all user interfaces, if AUTO-RESIZE is TRUE, the remaining items collapse toward the top to fill the gap left by the deleted item. If AUTO-RESIZE is FALSE in Windows, the remaining items are repositioned to evenly span the original radio-set dimensions; in character interfaces, the remaining items collapse upward as when AUTO-RESIZE is TRUE.

If the method is successful, it returns TRUE.

**Note:** A single call to DELETE can delete one or more items from a combo box or selection list, or one item from a radio set.
DELETE-CHAR( ) method

Deletes the character at the current text cursor position.

**Return type:** LOGICAL

**Applies to:** EDITOR widget

**Syntax**

```
DELETE-CHAR()
```

If the character is successfully deleted, the method returns TRUE.

DELETE-CURRENT-ROW( ) method

Deletes the most recently selected row from a browse and the results list.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
DELETE-CURRENT-ROW()
```

This method does not delete the record from the database and has no effect on the database buffer. If you then want to delete the database record associated with the row, use the DELETE statement.

If the row is successfully deleted from the browse and results list, the method returns TRUE.

DELETE-HEADER-ENTRY( ) method

Deletes the XML underlying a SOAP-header-entryref object, without deleting the object.

**Return type:** LOGICAL

**Applies to:** SOAP-header-entryref object handle

**Syntax**

```
DELETE-HEADER-ENTRY()
```

DELETE-LINE( ) method

Deletes the line that currently contains the text cursor.
DELETE-NODE( ) method

Unlinks and deletes the node and its sub-tree from the XML document. The ABL handle is not deleted.

Return type: LOGICAL
Applies to: X-noderef object handle

Syntax

DELETE-NODE( )

The following example demonstrates the use of the DELETE-NODE( ) method. Only use this when you are through using the node and all of its descendants.

h0ldNode:DELETE-NODE( ).

DELETE-RESULT-LIST-ENTRY( ) method

Deletes the current row of a query’s result list.

Return type: LOGICAL
Applies to: BROWSE widget, Query object handle

Syntax

DELETE-RESULT-LIST-ENTRY( )

For the browse, DELETE-RESULT-LIST-ENTRY( ) solves the following problem: Suppose you create a browse with a primary table and a secondary table, and in the primary table, the key to the secondary table changes. The AVM never displays the new secondary table because the result list entry contains the rowid of the original secondary table.

When you use DELETE-RESULT-LIST-ENTRY( ) together with CREATE-RESULT-LIST-ENTRY( ), you can update the result list entry and display the modified row without having to reopen the query.

For example, suppose you create a browse with customer.name, customer.salesrep, and salesrep.repname (from the Sports database). Then, in one record of the browse, you change customer.salesrep from “bbb” to “dkp.”
Without using DELETE-RESULT-LIST-ENTRY( ), the secondary record remains “bbb” until the query is reopened.

The following code fragment uses DELETE-RESULT-LIST-ENTRY( ) and CREATE-RESULT-LIST-ENTRY( ) to display the modified secondary record:

```
ON ROW-LEAVE OF my-brow DO:
   DEFINE VARIABLE num AS INTEGER NO-UNDO.
   DEFINE VARIABLE ok AS LOGICAL NO-UNDO.

   IF Customer.SalesRep:MODIFIED THEN DO:
      num = Customer.CustNum.
      ok = my-brow:DELETE-RESULT-LIST-ENTRY().
      /* DELETE-RESULT-LIST-ENTRY() disconnects recs from rec bufs, so re-read Customer and SalesRep records */
      FIND Customer WHERE Customer.CustNum EQ num.
      /* Create new result list entry with “new” secondary table's rowid */
      ok = my-brow:CREATE-RESULT-LIST-ENTRY().
      /* Update viewport */
      DISPLAY SalesRep.RepName WITH BROWSE my-brow.
   END.
END. /* ROW-LEAVE OF my-brow */
```

**Note:** During this operation, the query pointer must not move.

### DELETE-SELECTED-ROW( ) method

Deletes the $n$th selected row from a browse and the results list.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
DELETE-SELECTED-ROW ( $n$ )
```

$n$

An integer expression that specifies a selected row within the browse.

**Note:** Do not confuse the DELETE-SELECTED-ROW method (note the singular) with the DELETE-SELECTED-ROWS method (note the plural).

The AVM maintains a numbered list of selected rows, starting at 1. When the DELETE-SELECTED-ROW( $n$ ) method is encountered, the AVM searches this list to find the $n$th selected row.

This method does **not** delete the record from the database and has no effect on the database buffer. If you want to delete the database record associated with the row, use the DELETE statement.
If the row is successfully deleted, the method returns TRUE.

If you want to delete all selected rows, whether it is one or many, DELETE-SELECTED-ROWS is the preferred, optimized method for doing so.

DELETE-SELECTED-ROWS( ) method

Deletes all currently selected rows from a browse and the associated results list.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
DELETE-SELECTED-ROW( )
```

**Note:** Do not confuse the DELETE-SELECTED-ROW method (note the singular) with the DELETE-SELECTED-ROWS method (note the plural).

This method does **not** delete the record from the database and has no effect on the database buffer. If you want to delete the database record associated with the row, use the **DELETE** statement.

If the row is successfully deleted, the method returns TRUE.

DELIMITER attribute

The character that separates values input to or output from a combo box or selection list.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (column), COMBO-BOX widget, RADIO-SET widget, SELECTION-LIST widget

Delimiter character can have any ASCII value from 1 to 127. The default delimiter is a comma.

For browses, this attribute applies only to combo-box browse columns.

DESELECT-FOCUSED-ROW( ) method

Deselects the row with current focus.
DESELECT-ROWS( ) method

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
DESELECT-ROWS ( )
```

This method is ignored on single-select browse widgets, because focus follows selection.

DESELECT-ROWS( ) method

Deselects all currently selected rows in the browse and clears the associated record buffer.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
DESELECT-ROWS ( )
```

If the rows are successfully deselected, the method returns TRUE.

DESELECT-SELECTED-ROW( ) method

Deselects the $n$th selected row in a browse.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
DESELECT-SELECTED-ROW ( n )
```

$n$

An integer expression that specifies a selected row within the browse.

The AVM maintains a numbered list of selected rows, starting at 1. When the DESELECT-SELECTED-ROW( $n$ ) method is encountered, the AVM searches this list to find the $n$th selected row. If the row is successfully deselected, the method returns TRUE.

DETACH-DATA-SOURCE( ) method

Detaches a Data-source object from a temp-table buffer in a ProDataSet object.
DISABLE( ) method

Disables the radio set button. The selected radio-set button’s SCREEN-VALUE is changed to the first enabled radio set button or to the Unknown value (?) if all radio set buttons are disabled.

Return type: LOGICAL
Applies to: RADIO-SET widget

Syntax

DISABLE ( label )

label

A character-string expression that specifies the label of a button in the radio set.

If the operation is successful, the method returns TRUE.

DISABLE-AUTO-ZAP attribute

Indicates whether the AVM ignores the value of the AUTO-ZAP attribute.

Data type: LOGICAL
Access: Readable/Writable
Applies to: BROWSE widget (column), COMBO-BOX widget, FILL-IN widget

If DISABLE-AUTO-ZAP is TRUE, the AVM ignores the value of the AUTO-ZAP attribute and assumes it is FALSE. If the DISABLE-AUTO-ZAP attribute is FALSE, the AVM assumes the value of the AUTO-ZAP attribute is TRUE.

DISABLE-CONNECTIONS( ) method

Indicates that the AVM no longer listen for or accept new connections on the port associated with the server socket. However, all existing connections are still valid.
DISABLE-DUMP-TRIGGERS() method

Return type: LOGICAL
Applies to: Server socket object handle

Syntax

DISABLE-DUMP-TRIGGERS()

Returns TRUE if connections are disabled for this server socket object, even if the server socket object was never enabled or was already disabled.

DISABLE-DUMP-TRIGGERS() method

Allows a user to access a buffer object’s table without firing FIND triggers.

Return type: LOGICAL
Applies to: Buffer object handle

Syntax

DISABLE-DUMP-TRIGGERS()

To run this method, the end user must have CAN-DUMP privileges for the table.

Triggers cannot be disabled from a persistent procedure.

The FIND trigger remains disabled until the procedure in which it is disabled returns.

See also: DISABLE TRIGGERS statement

DISABLE-LOAD-TRIGGERS() method

Allows you to create or update a buffer object’s table without executing update triggers such as CREATE, WRITE, DELETE or ASSIGN.

Return type: LOGICAL
Applies to: Buffer object handle

Syntax

DISABLE-LOAD-TRIGGERS( allow-replication )

allow-replication

A LOGICAL expression indicating whether to disable or allow replication triggers. When TRUE, replication triggers are allowed to run, including the DELETE trigger. When FALSE, all triggers are disabled.

To run this method, you must have CAN-LOAD privileges for the table.

Triggers cannot be loaded from a persistent procedure.
The triggers remain disabled until the procedure in which it is disabled returns.

**Note:** The Disable Delete Trigger (`-disabledeltrig`) startup parameter disables the DELETE trigger when ALLOW-REPLICATION is on for the DISABLE TRIGGERS statement or the DISABLE-LOAD-TRIGGER() buffer method. For more information about this parameter, see *OpenEdge Deployment: Startup Command and Parameter Reference*.

**See also:** DISABLE TRIGGERS statement

---

**DISCONNECT( ) method**

Disconnects the client from the AppServer or Web service currently associated with the specified server handle. For the socket, closes the socket by terminating the connection between the socket and the port to which it is connected.

**Return type:** LOGICAL

**Applies to:** Server object handle, Socket object handle

**Syntax**

```
DISCONNECT ( )
```

When the AppServer receives a disconnect request:

- **For a state-reset or state-aware AppServer** — Control returns immediately to the client application, and any configured Disconnect procedure executes in the connected AppServer agent.

- **For a stateless AppServer** — Any configured Disconnect procedure executes in an available AppServer agent, then control returns to the client application.

- **For any AppServer with pending asynchronous requests** — All running or pending asynchronous requests are cancelled and the corresponding event procedure is called for each request. The CANCELLED attribute on the asynchronous request handle for all such cancelled requests is set to TRUE.

If an error occurs during the disconnection from an AppServer, DISCONNECT( ) returns FALSE. An error occurs if:

- The server handle is invalid.

- The server is either not connected or already disconnected.

If DISCONNECT( ) completes successfully, the CONNECTED( ) method returns FALSE. In addition, all attributes of the SERVER object (except for the FIRST PROCEDURE and LAST PROCEDURE attributes) are restored to their initial state. Specifically, SUBTYPE returns the Unknown value (?).

For more information on AppServers, see *OpenEdge Application Server: Developing AppServer Applications.*
For sockets, the AVM automatically closes a socket if it detects that the connection to which the socket is bound has failed or been terminated.

DISPLAY-MESSAGE( ) method

Displays a message in an alert box. The Debugger stores these messages and displays them to the user in an alert box when the Debugger regains control of an application.

Return type: INTEGER
Applies to: DEBUGGER system handle

Syntax

```
DISPLAY-MESSAGE ( char-expression )
```

`char-expression`

Any character expression.

This method appends a new line to `char-expression` before displaying the specified string. If the Debugger is initialized and `char-expression` is a valid character expression, this method returns TRUE. Otherwise, it returns FALSE with no effect.

Note: To use this method, you must have the Application Debugger installed in your OpenEdge environment.

DISPLAY-TIMEZONE attribute

The time zone offset, in minutes, used to display DATETIME-TZ data. The default value is the session’s time zone offset.

Data type: INTEGER
Access: Readable/Writeable
Applies to: SESSION system handle

If the format string for the DATETIME-TZ does not include the time zone offset, the AVM converts the DATETIME-TZ data to the local date and time and displays the data with the time zone offset specified by this attribute.

If the format string for the DATETIME-TZ includes the time zone offset, the AVM ignores this attribute and displays the data in the local time of the value, along with the time zone offset.

Set this attribute to the Unknown value (?) to use the session’s time zone offset for display.
DISPLAY-TYPE attribute

The type of display used in the session—"GUI" for a graphical display and "TTY" for a character-mode display.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

DOMAIN-DESCRIPTION attribute

The description of the authentication domain that authenticated the user represented by the Client-principal object. If not specified, the AVM returns a zero-length character string.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Client-principal object handle  

Once the Client-principal object is sealed, this attribute is read-only.

**See also:** DOMAIN-NAME attribute, DOMAIN-TYPE attribute

DOMAIN-NAME attribute

The name of the authentication domain that authenticated the user represented by the Client-principal object. You must set this attribute before you can seal the associated Client-principal object using the SEAL( ) method.

The authentication domain name you specify must match an authentication domain name registered in the trusted authentication domain registry for the Client-principal object. The AVM uses this domain name to find the associated authentication domain registry entry to validate the object before you can use it.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Client-principal object handle  

If you specify the Unknown value (?) or the empty string (""), the AVM generates a run-time error.

Once the Client-principal object is sealed, this attribute is read-only.
DOMAIN-TYPE attribute

The type of the authentication domain that authenticated the user represented by the Client-principal object. If not specified, the AVM returns a zero-length character string.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: Client-principal object handle

Once the Client-principal object is sealed, this attribute is read-only.

See also: DOMAIN-DESCRIPTION attribute, DOMAIN-TYPE attribute

DOWN attribute

Indicates the number of iterations in a down frame that contain data or number of potential rows in a browse widget. For a one-down frame, the value of DOWN is 1. Sets the number of browse-rows that appear in the viewport.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget, FRAME widget

In character mode, the DOWN attribute must be set before the browse is realized. Attempting to set the attribute after realization of the browse causes a run-time error.

If you change the value of a browse’s DOWN attribute, you change the number of rows that appear in the viewport, which might change the value of the browse’s HEIGHT-CHARS and HEIGHT-PIXELS attributes. Changing the value of a browse’s DOWN attribute does not change the value of the browse’s ROW-HEIGHT-CHARS and ROW-HEIGHT-PIXELS attributes.

Note: If the browse’s height is set with the DOWN attribute and a browse column is added using the ADD-CALC-COLUMN( ), ADD-COLUMNS-FROM( ) or ADD-LIKE-COLUMN( ) methods, the browse’s height may change to ensure that the number of DOWN is preserved.

DRAG-ENABLED attribute

Indicates whether the user can simultaneously hold down the mouse select button and drag the mouse cursor through the selection list. As the mouse cursor passes over an item, the item is highlighted. When the user releases the select button, the highlighted item becomes the selected item.
**DROP-TARGET attribute**

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SELECTION-LIST widget

In this style of selecting, a user can deselect an item only by selecting another. Once an item is selected, the list cannot revert to its unselected state.

The default value for this attribute is TRUE.

**Note:** In Windows, DRAG-ENABLED is always TRUE.

You can set this attribute only before the widget is realized.

---

**DROP-TARGET attribute**  
(Windows only; Graphical interfaces only)

Indicates whether the widget can accept dropped files.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

If DROP-TARGET is TRUE, dragging one or more files over the widget causes the mouse pointer to change to indicate that the widget can accept the files. The default value of DROP-TARGET is FALSE.

For related information, see the reference entries for the DROP-TARGET option of the DEFINE BROWSE statement, DEFINE BUTTON statement, DEFINE FRAME statement, and DEFINE VARIABLE statement.

---

**DUMP-LOGGING-NOW( ) method**

Writes the accumulated query statistics for the specified query to the log file.

**Return type:** LOGICAL  
**Applies to:** Query object handle

**Syntax**

```plaintext
query-handle:DUMP-LOGGING-NOW(reset-expression)
```

`query-handle`  
A variable of type HANDLE that represents the handle to a query object.
reset-expression

A logical expression where TRUE indicates that the AVM clear the query statistics after writing the statistics to the log file, and FALSE indicates that the AVM leave the query statistics unchanged.

If the AVM writes the query statistics to the log file successfully, the method returns TRUE. If the AVM does not write the query statistics to the log file, the method returns FALSE. The AVM does not write query statistics to the log file under the following conditions:

- QryInfo logging for the specified query was not turned on before the query started.

  To turn on basic logging for an individual query, you must set the BASIC-LOGGING attribute to TRUE before a query starts. For a dynamically opened query, this is before the QUERY-PREPARE( ) method. For a statically opened query, this is before the OPEN QUERY statement.

- QryInfo logging was turned off for the specified query, or all queries, before the query completed.

You can use the DUMP-LOGGING-NOW( ) method only when the logging level of the QryInfo log entry type is set to level 2 (Basic) or higher. To set the logging level of the QryInfo log entry type, use the LOG-ENTRY-TYPES attribute or the Log Entry Types (-logentrytypes) startup parameter with the logging level option.

If the logging level of the QryInfo log entry type is set to level 2 (Basic), the DUMP-LOGGING-NOW( ) method writes query statistics to the log file only if the BASIC-LOGGING attribute is set to TRUE before the query started.

For more information about the Log Entry Types (-logentrytypes) startup parameter, see OpenEdge Deployment: Startup Command and Parameter Reference.

For more information about logging query statistics, see OpenEdge Development: Debugging and Troubleshooting.

DYNAMIC attribute

Indicates whether the widget is dynamic or static.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>LOGICAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>BROWSE widget, Buffer object handle, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU widget, MENU-ITEM widget, ProDataSet object handle, Query object handle, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, Temp-table object handle, TEXT widget, TOGGLE-BOX widget, WINDOW widget</td>
</tr>
</tbody>
</table>

If the DYNAMIC attribute is TRUE, the widget is dynamic, otherwise it is static.
EDGE-CHARS attribute

The width, in character units, of the edge of a rectangle.

Data type: DECIMAL
Access: Readable/Writeable
Applies to: RECTANGLE widget

EDGE-PIXELS attribute

The width, in pixels, of the edge of a rectangle.

Data type: INTEGER
Access: Readable/Writeable
Applies to: RECTANGLE widget

EDIT-CAN-PASTE attribute
(Windows only; Graphical interfaces only)

Indicates whether the Clipboard contains data that can be pasted into the widget.

Data type: LOGICAL
Access: Readable
Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget

If the Clipboard contains data that can be pasted into the widget, EDIT-CAN-PASTE is TRUE. Otherwise, it is FALSE.

For browses, this attribute applies only to fill-in and combo-box browse columns.

EDIT-CAN-UNDO attribute
(Windows only; Graphical interfaces only)

Indicates whether the widget can undo the last modification.

Data type: LOGICAL
Access: Readable
Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget

If the widget can undo the last modification, EDIT-CAN-UNDO has the value TRUE, otherwise it has the value FALSE.

If you set EDIT-CAN-UNDO to any value, the AVM empties the undo buffer.

For browses, this attribute applies only to fill-in and combo-box browse columns.
EDIT-CLEAR( ) method
(Windows only; Graphical interfaces only)

Deletes the selected text.

Return type: LOGICAL

Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget

Syntax

EDIT-CLEAR( )

If the widget performs the operation successfully, the method returns TRUE. Otherwise, it returns FALSE.

For browses, this method applies only to fill-in and combo-box browse columns.

EDIT-COPY( ) method
(Windows only; Graphical interfaces only)

Copies the currently selected text in the widget to the Clipboard.

Return type: LOGICAL

Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget

Syntax

EDIT-COPY( )

If the widget performs the operation successfully, the method returns TRUE. Otherwise, it returns FALSE.

For browses, this method applies only to fill-in and combo-box browse columns.

EDIT-CUT( ) method
(Windows only; Graphical interfaces only)

Copies the currently selected text in the widget to the Clipboard and then deletes the selected text.

Return type: LOGICAL

Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget

Syntax

EDIT-CUT( )
If the widget performs the operation successfully, the method returns TRUE. Otherwise, it returns FALSE.

For browses, this method applies only to fill-in and combo-box browse columns.

EDIT-PASTE( ) method
(Windows only; Graphical interfaces only)

Copies the currently selected text of the Clipboard into the widget at the current cursor position, if the Clipboard contains text data.

**Return type:** LOGICAL

**Applies to:** BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget

**Syntax**

```
EDIT-PASTE ( )
```

If the widget performs the operation successfully, the method returns TRUE. Otherwise, it returns FALSE.

For browses, this method applies only to fill-in and combo-box browse columns.

EDIT-UNDO( ) method
(Windows only; Graphical interfaces only)

Makes the editor undo its most recent edit if possible.

**Return type:** LOGICAL

**Applies to:** BROWSE widget (cell), COMBO-BOX widget, EDITOR widget

**Syntax**

```
EDIT-UNDO ( )
```

If the widget performs the operation successfully, the method returns TRUE. Otherwise, it returns FALSE.

For browses, this method applies only to fill-in and combo-box browse columns.

EMPTY attribute

Indicates whether the SCREEN-VALUE attribute for the editor contains text.
EMPTY-DATASET( ) method

Data type: LOGICAL
Access: Readable
Applies to: EDITOR widget

The EMPTY attribute is TRUE if the editor contains no text (that is, the editor’s SCREEN-VALUE is null).

EMPTY-DATASET( ) method

Empties a ProDataSet object of all records in its associated temp-tables.

Return type: LOGICAL
Applies to: ProDataSet object handle

Syntax

EMPTY-DATASET ( )

When you invoke this method, the ABL Virtual Machine (AVM) sets the ORIGIN-HANDLE attribute on any changes temp-tables corresponding to the source temp-tables of this ProDataSet to the Unknown value (?).

EMPTY-TEMP-TABLE( ) method

Deletes all records from a temp-table associated with a buffer object.

When you empty a temp-table that is defined as UNDO within a transaction, the ABL Virtual Machine (AVM) deletes the records individually. This is less efficient than emptying the temp-table outside the transaction, where the AVM deletes all records in the temp-table as a unit.

Return type: LOGICAL
Applies to: Buffer object handle

Syntax

EMPTY-TEMP-TABLE ( )

When you invoke this method on a buffer, the AVM sets the ORIGIN-HANDLE attribute on any changes temp-table corresponding to the source temp-table associated with this buffer object to the Unknown value (?).

Note: This method corresponds to the EMPTY TEMP-TABLE statement.
**ENABLE( ) method**

Enables the specified radio button within the radio set.

**Return type:** LOGICAL  
**Applies to:** RADIO-SET widget

**Syntax**

```
ENABLE ( label )
```

`label`

A character-string expression that specifies the label of a radio button.

If the operation is successful, the method returns TRUE.

---

**ENABLE-CONNECTIONS( ) method**

Specifies the TCP/IP port that the AVM uses to listen for new connections. Once called, the AVM automatically listens for and accepts new connections for the specified port.

**Return type:** LOGICAL  
**Applies to:** Server socket object handle

**Syntax**

```
ENABLE-CONNECTIONS( connection-parms )
```

`connection-parms`

A character string expression that contains a space-separated list of one or more socket connection parameters.

Table 77 describes the socket connection parameters you can include in this string.

**Table 77: Socket connection parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-S socket-port</td>
<td>The TCP/IP port number that the AVM should listen to and accept connections on. You can specify either an explicit port number or a TCP service name. If you use a TCP service name, the method uses the port number associated with that name in the TCP/IP services file.</td>
</tr>
<tr>
<td>-pf filename</td>
<td>Optional. A text file containing any of the socket connection parameters described in this table. If this file contains any other OpenEdge startup parameters, this method ignores them.</td>
</tr>
</tbody>
</table>
Neither an AppServer nor a WebSpeed agent can act as a socket server, since they are already listening on a port. ENABLE-CONNECTIONS is only valid from batch clients, GUI clients and character clients. This method will generate an error if it is called from an invalid application.

This method will also generate an error if it is called multiple times without the DISABLE-CONNECTION( ) method being called in between.

**Note:** Connections to an SSL-enabled server socket require the management of public keys on the client (SSL client) and private keys on the server (SSL server). For ABL sockets, the SSL client is the ABL session initiating the SSL connection on a socket object and the SSL server is the ABL session enabling SSL connections on a server socket object. For information on using SSL to secure an ABL socket connection, see the sections on sockets in OpenEdge Development: Programming Interfaces. For more information on SSL and managing private key and digital certificate stores for OpenEdge SSL clients and servers, see OpenEdge Getting Started: Core Business Services.
ENABLE-EVENTS( ) method
(Windows only)

Enables event notification for automation objects.

**Return type:** CHARACTER

**Applies to:** Automation Object

**Syntax**

```
ENABLE-EVENTS ( event-proc-prefix )
```

**event-proc-prefix**

A character-string expression that the AVM prepends to event names. The resulting string is the name of the internal procedure the AVM runs when an event is fired. During an event notification, all running procedures and all persistent procedures are searched to find a procedure with the name matching `event-proc-prefix.eventname` (for example, `ExcelWB.SelectionChanged`).

ENCODING attribute

Returns the name of the character encoding used to encode the contents of an XML document. The default encoding is UTF-8.

**Data type:** CHARACTER

**Access:** Readable/Writable

**Applies to:** X-document object handle, SAX-writer object handle

For an X-document object, the AVM sets the ENCODING attribute to the encoding name specified in the XML document’s encoding declaration when you load an XML document using the LOAD( ) method (Handle).

You can also set the ENCODING attribute to the name of the character encoding to use when saving an XML document using the SAVE( ) method. The AVM records this character encoding in the encoding declaration in the XML document’s prologue. If you do not set the ENCODING attribute, when you save the document, the document will not have an encoding declaration in its prologue, but the document will be saved with the default encoding of UTF-8.

For a SAX-writer object, you can set the ENCODING attribute to the name of the character encoding to use when writing the XML document. You can set this attribute only when the WRITE-STATUS is either SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. That is, you can only change this attribute when the writer is not writing, otherwise it fails and generates an error message. The AVM records this character encoding in the encoding declaration in the XML document’s prologue. If you do not set the ENCODING attribute, when you write the document, the document will not have an encoding declaration in its prologue, but the document will be written with the default encoding of UTF-8.

The encoding name must be an Internet Assigned Numbers Authority (IANA) name supported by the ABL XML Parser. Table 78 lists the names of the supported IANA encodings and their corresponding ABL code pages.

</tbody>
</table>

**ENCRIPT-AUDIT-MAC-KEY() method**

Encrypts and encodes the specified character expression and returns an encrypted character value that you can store for later use in message authentication code (MAC) operations.
ENCRYPTION-SALT attribute

**Return type:** CHARACTER  
**Applies to:** AUDIT-POLICY system handle

### Syntax

```plaintext
ENCRIPT-AUDIT-MAC-KEY( encrypt-key )
```

`encrypt-key`

A character expression containing the key to encrypt. The AVM converts this key to UTF-8 before encrypting it and storing it, which ensures a consistent value regardless of code page settings.

The following code fragment illustrates how to use the ENCRYPT-AUDIT-MAC-KEY( ) method:

```plaintext
DEFINE VARIABLE val AS CHARACTER NO-UNDO.
DEFINE VARIABLE key AS CHARACTER NO-UNDO INITIAL “Open Sesame”.
... 
val = AUDIT-POLICY:ENCRIPT-AUDIT-MAC-KEY(key).
... 
_db-detail._db-mac-key = val.
```

---

ENCRYPTION-SALT attribute

The default salt value (a random series of bytes) to use with the GENERATE-PBE-KEY function. The default value is the Unknown value (?), which indicates that no salt value is used to generate the password-based encryption key.

**Data type:** RAW  
**Access:** Readable/Writeable  
**Applies to:** SECURITY-POLICY system handle

If specified, this salt value is combined with a password value and hashed some number of times to generate a password-based encryption key (using the algorithm specified by the PBE-HASH-ALGORITHM attribute and the number of iterations specified by the PBE-KEY-ROUNDS attribute).

When set, only the first 8 bytes are used. If the value has fewer than 8 bytes, it is padded at the end with zero-value bytes.

You can use the GENERATE-PBE-SALT function to generate a salt value, which can help to ensure that the password key value is unique.

You are responsible for generating, storing, and transporting this value.
END-DOCUMENT( ) method

Closes the XML document represented by a SAX-writer object.

Return type: LOGICAL
Applies to: SAX-writer object handle

Syntax

```
END-DOCUMENT( )
```

Closes the XML stream. This is the logical conclusion of creating the XML document.

If you call this method before the START-DOKUMENT method, the method fails. WRITE-STATUS must not be SAX-WRITE-IDLE or SAX-WRITE-COMPLETE when you call this method. END-DOCUMENT changes WRITE-STATUS to SAX-WRITE-COMPLETE.

If the STRICT attribute is TRUE and the final tag has not been closed (that is, the root node), then this method fails.

See also: START-DOKUMENT( ) method

END-ELEMENT( ) method

Ends an XML node based upon the name of the node with in a SAX-writer object.

Return type: LOGICAL
Applies to: SAX-writer object handle

Syntax

```
END-ELEMENT( name [, namespace-URI ] )
```

name
A CHARACTER or LONGCHAR expression evaluating to the fully qualified or unqualified name of the element.

namespace-URI
A CHARACTER or LONGCHAR expression evaluating to the URI of the element. If the element doesn’t contain a namespace, it can evaluate to an empty string ("") or the Unknown value (?).

Ends an XML node and sets the WRITE-STATUS to SAX-WRITE-ELEMENT.
For every invocation of END-ELEMENT, there must be a preceding corresponding call of the START-ELEMENT method. All the parameter values must match for the methods to correspond. The method does not resolve namespaces. Instead, it matches the namespace against the corresponding START-ELEMENT value.

If the STRICT attribute is TRUE and the method does not match a preceding START-ELEMENT call, then the method fails.

See also: START-ELEMENT( ) method

**END-EVENT-GROUP( ) method**

Indicates the end of a group of related events in the current session.

**Return type:** LOGICAL

**Applies to:** AUDIT-CONTROL system handle

**Syntax**

```
END-EVENT-GROUP( )
```

After calling this method, the EVENT-GROUP-ID attribute is cleared for all connected audit-enabled databases and is no longer recorded in audit event records for this event group.

There can be only one active event group per session at any one point in time. To set a different event group for the session, you can:

- Call the END-EVENT-GROUP( ) method, to end the current event group, and then call the BEGIN-EVENT-GROUP( ) method to begin the new event group.
- Call the BEGIN-EVENT-GROUP( ) method to begin the new event group. If there is an existing event group in effect, the AVM ends the existing event group before beginning the new event group.

Calling this method does not generate an audit event or an audit record.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

See also: BEGIN-EVENT-GROUP( ) method, EVENT-GROUP-ID attribute

**END-FILE-DROP( ) method**  
* (Windows only; Graphical interfaces only)  

Terminates a drag-and-drop operation and frees the memory allocated by Windows to hold the names of the dropped files.

**Return type:** BOOLEAN

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget,
RADIO-SET widget, SELECTION-LIST widget, SLIDER widget,
TOGGLE-BOX widget, WINDOW widget

**Syntax**

```
END-FILE-DROP ( )
```

This method returns TRUE if it is successful. If there is no current drag-and-drop operation,
GET-DROPPED-FILE( ) returns FALSE.

---

**END-USER-PROMPT attribute**

A freeform string that WebClient uses when prompting for a userid and password, if it does not
find those values in the security cache.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** CODEBASE-LOCATOR system handle

---

**ENTRY( ) method**

Returns the character-string value of the specified list entry.

**Return type:** CHARACTER

**Applies to:** BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

**Syntax**

```
ENTRY ( list-index )
```

**list-index**

An integer expression that specifies an entry within the combo-box list or selection list.

For browses, this method applies only to combo-box browse columns.

---

**ENTRY-TYPES-LIST attribute**

Returns a character string containing a comma-separated list of all valid entry types for the
current OpenEdge environment. For DataServer server logging, the string contains the valid
entry types against the logical database specified by the DB-CONTEXT attribute.
**ERROR attribute**

A compile-time or run-time error condition.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** Asynchronous request object handle, Buffer object handle, COMPILER system handle, ERROR-STATUS system handle, ProDataSet object handle, Temp-table object handle

The ERROR attribute corresponds to the **ERROR function**.

For the asynchronous request object handle, the ERROR attribute indicates that the ERROR condition was encountered during the processing of an AppServer or Web Server request. If the COMPLETE attribute is FALSE, the value of this attribute is the Unknown value (?). This attribute is set immediately before the event procedure is executed.

For the COMPILER system handle, the ERROR attribute indicates whether an error occurred in the preceding compilation. If no error occurred in the preceding compilation, the value of ERROR is the Unknown value (?).

For the ProDataSet object handle, Temp-table object handle, and Buffer object handle, the ERROR attribute indicates whether an error occurred during a FILL or SAVE-ROW-CHANGES operation.

For a ProDataSet object handle or a temp-table object handle, the ERROR attribute is reset to FALSE when one of the following methods removes the object’s before-image records:

- FILL( ) method
- EMPTY-DATASET( ) method
- MERGE-CHANGES( ) method
- ACCEPT-CHANGES( ) method
- REJECT-CHANGES( ) method

For the Buffer object handle, this attribute causes the row to be backed out rather than merged with the MERGE-CHANGES( ) method or the MERGE-ROW-CHANGES( ) method.

This attribute is marshalled between the client and the AppServer.

For the ERROR-STATUS system handle, the ERROR attribute indicates whether the ABL ERROR condition was raised in the most recent statement that used the NO-ERROR option. If no ERROR condition was raised in that statement, the value of the ERROR attribute is FALSE.
The ERROR attribute is writeable for a ProDataSet object, a Temp-table object, and a Buffer object. You can set the ERROR attribute programmatically in order to manage the application response to errors. For example, you might set the ERROR attribute to FALSE in order to ignore all errors that might be returned for a statement using the NO-ERROR option. However, note that manually setting this attribute has no affect on ABL error management. Thus, if you set the ERROR attribute to TRUE, the AVM does not also raise the ERROR condition.

**Note:** Statements such as COMPILE that handle errors as part of their normal function do not raise the ABL ERROR condition. For example, the COMPILE statement does not raise the ERROR condition when it encounters compilation errors in a procedure.

---

**ERROR-COLUMN attribute**

The character position at which a compiler error occurred.

- **Data type:** INTEGER
- **Access:** Readable
- **Applies to:** COMPILER system handle

If no error occurred in the preceding compilation, the value of ERROR-COLUMN is the Unknown value (?)

---

**ERROR-OBJECT-DETAIL attribute**

Identifies the SOAP-fault object that contains SOAP fault message detail.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:** ERROR-STATUS system handle

If a Web service operation generates a SOAP fault message, the AVM generates the following error:

```
Web service %s<operation> failed. SOAP faultstring is %s (nnnn)
```

The complete SOAP fault error message is returned to the AVM as part of the ERROR-STATUS system handle.

If the ABL application invokes the Web service operation with the NO-ERROR option on the RUN statement, any errors that occur as a result of the operation are suppressed. In this case, the application can access the SOAP fault message detail using the SOAP-fault and SOAP-FAULT-DETAIL object handles. Otherwise, the AVM displays the error message to the end user.
**ERROR-ROW attribute**

The line number at which a compiler error occurred.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** COMPILER system handle

If no error occurred in the preceding compilation, the value of ERROR-ROW is the Unknown value (?).

**ERROR-STACK-TRACE attribute**

This attribute controls whether or not the CallStack property on error objects can be used. Because the CallStack feature is for debugging and can slow system performance, error objects should not save call stacks in a production environment. This attribute allows you to disable the CallStack property on all error objects. When this attribute is FALSE, the default value, the CallStack property on an error object will be the Unknown value (?).

You can also set this session attribute using the -errorstack startup parameter.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

**ERROR-STRING attribute**

An arbitrary string value associated with a buffer or temp-table object that provides descriptive information about an error on that object.

**Data type:** CHARACTER  
**Access:** Readable/Writable  
**Applies to:** Buffer object handle, Temp-table object handle

Setting the attribute does not in any way signal an error condition to ABL. The AVM does not inspect this string, or take action based on its value.

The AVM automatically clears this attribute by setting its value to the empty string ("") when one of the following occurs:

- The FILL( ) method is used on any ProDataSet object containing a temp-table, on one of its member temp-table objects, or on a parent buffer that cascades down through that temp-table object.
- The EMPTY-TEMP-TABLE( ) method is used on a temp-table object buffer.
- You set the ERROR-STRING attribute, for the temp-table object, to the empty string ("").

The number of characters in this string is limited to 3K.
EVENT-GROUP-ID attribute

Returns the universally unique identifier (UUID) for the audit event group in effect for the current session, as a Base64 character string. The UUID is 22 characters in length (the two trailing Base64 pad characters are removed).

Data type: CHARACTER  
Access: Readable  
Applies to: AUDIT-CONTROL system handle

The value of this attribute is set by the BEGIN-EVENT-GROUP( ) method, and cleared by the END-EVENT-GROUP( ) method. This value is recorded in all audit event records generated for this audit event group until you either end the current audit event group or begin a different audit event group.

If no audit event group is in effect, this method returns the Unknown value (?).

See also: BEGIN-EVENT-GROUP( ) method, END-EVENT-GROUP( ) method

EVENT-PROCEDURE attribute

The name of the internal procedure to run as the event procedure for an asynchronous request.

Note: Applies only if the ASYNCHRONOUS attribute is TRUE.

Data type: CHARACTER  
Access: Readable  
Applies to: Asynchronous request object handle, Call object handle

The name of this internal procedure is the same as the name of the event procedure as specified by the EVENT-PROCEDURE option on the RUN statement. If the EVENT-PROCEDURE option is not specified, this attribute is set to the empty string ("").

EVENT-PROCEDURE-CONTEXT attribute

The procedure handle of the active procedure context where the event procedure is defined for an asynchronous request.

Note: Applies only if the ASYNCHRONOUS attribute is TRUE.
**EVENT-TYPE attribute**

Data type: HANDLE
Access: Readable
Applies to: Asynchronous request object handle, Call object handle

This procedure handle is the same as the handle specified by the EVENT-PROCEDURE...IN procedure-context option of the RUN statement that executes this request. If the EVENT-PROCEDURE...IN option is not specified (the default), this attribute is set to the value of the THIS-PROCEDURE system handle at the time the RUN statement was executed.

---

**EVENT-TYPE attribute**

The type of the last event.

Data type: CHARACTER
Access: Readable
Applies to: LAST-EVENT system handle

Valid event types are:

- "KEYPRESS" — When the detected event is a keyboard event identified by key label, such as ESC, CTRL+A, or A.
- "MOUSE" — When the detected event is a portable or three-button mouse event, such as MOUSE-SELECT-UP or LEFT-MOUSE-UP.
- "PROGRESS" — When the detected event is a high-level ABL event. These include all events identified as direct manipulation, key function, developer, and other miscellaneous events, such as SELECTION, DELETE-LINE, U1, or CHOOSE.

---

**EXCLUSIVE-ID attribute**

The ID assigned to a state-aware cookie. Intended for internal use only.

Data type: CHARACTER
Access: Readable
Applies to: WEB-CONTEXT system handle

---

**EXECUTION-LOG attribute**

Determines whether the AVM traces the execution of procedures, user-define functions, and the publish and subscribe statements in the execution log. Intended for internal use only.
EXPAND attribute

How to set the size of a horizontal radio set.

Data type: LOGICAL
Access: Readable/Writable
Applies to: RADIO-SET widget

This attribute applies to radio sets whose HORIZONTAL attribute are set to TRUE (for horizontal alignment).

If TRUE, the size for each button is equal to the width of the button with the longest label. If FALSE, the size for each button is set according to its label.

You can set this attribute only before the widget is realized.

EXPANDABLE attribute
(Graphical interfaces only)

Indicates whether the AVM extends the right-most browse column to the right edge of the browse. This covers white space that appears when the browse is wider than the sum of the widths of the browse columns.

Data type: LOGICAL
Access: Readable/Writable
Applies to: BROWSE widget

If you set a browse’s EXPANDABLE attribute to TRUE, the AVM extends the right-most browse column to the right edge of the browse, if necessary, to cover any white space that might appear-unless you explicitly set the width of the right-most browse column using the WIDTH-CHARS or WIDTH-PIXELS attribute. The right-most browse column expands to the right anytime the browse or another browse column is resized.

If the browse has a horizontal scroll bar, no white space appears between the right-most browse column and the right edge of the browse, and the right-most browse column does not expand to the right.

If EXPANDABLE is TRUE and a browse column’s VISIBLE attribute is changed, the last column’s width may be changed.

When adding dynamic browse columns to a browse, it is best to keep EXPANDABLE turned off until all columns are added.
**EXPORT( ) method**  
**AppServer only**

Creates and modifies an AppServer’s export list, which specifies the remote procedures that a client application can execute in the current AppServer session.

**Return type:** LOGICAL  
**Applies to:** SESSION system handle

**Syntax**

```
EXPORT( [list] )
```

*list*  
A comma-separated list of procedure names and name-patterns. EXPORT( ) ignores white space (blank, tab, and newline) at the beginning and end of an entry. The only wildcard EXPORT( ) supports is the asterisk (*). For more information on wildcards, see the reference entry for the MATCHES function.

The EXPORT( ) method applies only to AppServers. That is, if the REMOTE attribute of the SESSION handle is FALSE, EXPORT( ) does nothing and returns FALSE.

The EXPORT( ) method can be called repeatedly within the context of the AppServer instance. Each time EXPORT( ) is called, the AppServer instance adds the procedures in *list* to its export list. If you do not specify *list*, the EXPORT( ) method resets the export list to empty.

The EXPORT( ) method performs pattern matching by comparing two procedure names character-by-character, taking wildcards into account. Procedure names must match exactly. Case (uppercase and lowercase) is significant.

If the EXPORT( ) method is never called, a client application can call any procedure in the AppServer’s PROPATH. Once EXPORT( ) is called in the context of an AppServer, a client application can call only the procedures in the export list.

Typically, the Connect procedure or Startup procedure of an AppServer calls the EXPORT( ) method, depending on the operating mode. For example, where you might call it from the Connect procedure on a state-reset or state-aware AppServer, you would probably call it from the Startup procedure on a stateless AppServer. For more information on Connect procedures, see the reference entry for the CONNECT( ) method (AppServer). For more information on both types of procedures and the AppServer, see *OpenEdge Application Server: Developing AppServer Applications*.

**EXPORT-PRINCIPAL( ) method**

Exports a sealed Client-principal object, with its currently defined property and attribute settings, by converting it to a raw value. You can assign this value to a RAW variable and send it to another client (such as the AppServer™). The receiving client can then import the raw value into another Client-principal object handle, using the IMPORT-PRINCIPAL( ) method, and use the imported object to set a user ID using either the SET-CLIENT( ) method or SET-DB-CLIENT function.
**Return type:** RAW  
**Applies to:** Client-principal object handle

**Syntax**

```plaintext
EXPORT-PRINCIPAL( )
```

If the Client-principal object is in the initial (presealed) LOGOUT state, the AVM generates a run-time error.

Calling this method does not generate an audit event or an audit record.

The following code fragment illustrates how to use the EXPORT-PRINCIPAL() method:

```plaintext
DEFINE VARIABLE hCP AS HANDLE NO-UNDO.
DEFINE VARIABLE raw-cp AS RAW NO-UNDO.
... CREATE CLIENT-PRINCIPAL hCp.
raw-cp = hCP:EXPORT-PRINCIPAL( ).
```

**See also:** IMPORT-PRINCIPAL( ) method, SET-CLIENT( ) method, SET-DB-CLIENT function

---

**EXTENT attribute**

The number of elements in an array field.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer-field object handle

**Note:** The EXTENT attribute corresponds to the EXTENT function.

---

**FETCH-SELECTED-ROW( ) method**

Fetches the \( n \)th selected row in a browse and puts the row into the database buffer. In other words, this method specifies one row from the one-based index into all currently selected rows and puts that row into the record buffer.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```plaintext
FETCH-SELECTED-ROW ( n )
```
FGCOLOR attribute

$n$

An integer expression that specifies a selected row within the browse.

The AVM maintains a numbered list of selected rows, starting at 1. The AVM builds this numbered list as the user selects rows in the browse. When you call the FETCH-SELECTED-ROW method, the AVM searches this list to find the $n$th row selected by the user.

FGCOLOR attribute
(Graphical interfaces only)

The color number for the foreground color of the widget.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (browse, column, and cell), COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

The color number represents an entry in the color table maintained by the COLOR-TABLE handle.

For a browse cell, it specifies the color of a specific cell in the view port. You can set this color only as the cell appears in the view port during a ROW-DISPLAY event.

You cannot set this attribute for a BUTTON widget.

You cannot set this attribute for combo-boxes, selection-lists, editors, or native fill-in fields (VIEW-AS FILL-IN NATIVE) when they are disabled (not SENSITIVE).

Setting the FGCOLOR attribute for any of the following field-level widgets within a dialog-box or frame overrides any INHERIT-FGCOLOR attribute or option settings: BROWSE, COMBO-BOX (all types), EDITOR, FILL-IN (NATIVE and Enabled), and SELECTION-LIST.

**Note:** This attribute has no meaning for control-frames because the ActiveX control visualization constitutes the foreground.

**See also:** BGCOLOR attribute, Frame phrase, INHERIT-FGCOLOR attribute

FILE-CREATE-DATE attribute
(Windows only)

Indicates the date on which the specified file was created.
FILE-CREATE-TIME attribute

(Windows only)

Indicates the time when the specified file was created.

Data type: INTEGER
Access: Readable
Applies to: FILE-INFO system handle

FILE-MOD-DATE attribute

Indicates the last date the specified file was modified.

Data type: DATE
Access: Readable
Applies to: FILE-INFO system handle

This attribute is supported on all platforms.

FILE-MOD-TIME attribute

Indicates the last time the specified file was modified.

Data type: INTEGER
Access: Readable
Applies to: FILE-INFO system handle

This attribute is supported on all platforms.

FILE-NAME attribute

The name of the file associated with a handle. Returns the empty string for a Web service procedure.

The FILE-NAME attribute of the COMPILER handle is maintained only for backward compatibility. Use the GET-FILE-NAME( ) method, instead.
### FILE-OFFSET attribute

The character offset in the source file in which a Compiler error occurred.

**Data type:**  INTEGER  
**Access:**  Readable  
**Applies to:**  COMPILER system handle  

If no error occurred in the preceding compilation, the value of FILE-OFFSET is the Unknown value (?).

### FILE-SIZE attribute

Indicates the size of the specified file.

**Data type:**  INTEGER  
**Access:**  Readable  
**Applies to:**  FILE-INFO system handle  

This attribute is supported on all platforms.
FILE-TYPE attribute

A string of characters that indicate the type of file that is currently specified for the FILE-INFO handle.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** FILE-INFO system handle

The character string specifies two classes of file types—one type per file from the first class and one or more types per file from the second class. Table 79 lists the file type characters from the first class of file types.

<table>
<thead>
<tr>
<th>File type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>The file is a directory.</td>
</tr>
<tr>
<td>F</td>
<td>The file is a standard file or FIFO pipe (UNIX systems).</td>
</tr>
<tr>
<td>M</td>
<td>The file is a member of an ABL procedure library.</td>
</tr>
<tr>
<td>S</td>
<td>The file is a special device (UNIX systems).</td>
</tr>
<tr>
<td>X</td>
<td>The file type is unknown. (Contact your Progress Software Corporation Technical Support representative if you receive this value.)</td>
</tr>
</tbody>
</table>

Table 80 lists the file type characters from the second class of file types.

<table>
<thead>
<tr>
<th>File type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>The file is hidden.</td>
</tr>
<tr>
<td>L</td>
<td>The file is a symbolic link (UNIX systems).</td>
</tr>
<tr>
<td>P</td>
<td>The file is a pipe file (UNIX systems).</td>
</tr>
<tr>
<td>R</td>
<td>The file is readable.</td>
</tr>
<tr>
<td>W</td>
<td>The file is writeable.</td>
</tr>
</tbody>
</table>

**FILL( ) method**

Fills a ProDataSet object, recursively, based on its defined data sources, data relations, and queries. You can fill a ProDataSet object completely by running FILL on the ProDataSet handle itself, or partially by starting at the level of one of its member Buffer objects.
**FILL( ) method**

**Return type:** LOGICAL

**Applies to:** ProDataSet object handle, Buffer object handle

**Syntax**

```
FILL( )
```

You can define a query for the data source of a ProDataSet member buffer at any level of the ProDataSet object to select the records to fill in one FILL operation. You can also use the FILL-WHERE-STRING attribute to override the WHERE clause in the query for the data source during a FILL operation.

You can perform a FILL operation on a ProDataSet object or one of its member buffer objects any number of times. You might do this, for example, to load data in a ProDataSet object or buffer after you have modified a data-source object query or attached to a different data-source object.

You can specify the FILL mode to direct the FILL operation for a ProDataSet member buffer using the FILL-MODE attribute. The default FILL-MODE is MERGE. When FILL-MODE is REPLACE, the BEFORE-ROW-FILL event handler is run after the original ProDataSet row is copied into the ProDataSet buffer.

A number of built-in events fire automatically at different points during the FILL process, for example before the FILL, after a record is created in the temp-table, and so on. For more information about ProDataSet events, see the “ProDataSet events” section on page 1846.

You can recursively fill a ProDataSet with self-referencing elements, for example, bill-of-materials parent/child tables or organization chart manager/employee tables. For a static ProDataSet, use the RECURSIVE option of the data-relation object. For a dynamic ProDataSet, use the ADD-RELATION( ) method of the ProDataSet object handle.

**Note:** When executing the FILL( ) method on a temp-table or ProDataSet, and the default buffer of one of the contained temp-tables is available, there is no guarantee as to the state of that buffer after the method finishes executing. The record buffer may not be available. If default buffer availability is an issue, it is suggested that a named buffer be used with this method. A named buffer can be created with the DEFINE BUFFER statement.

For more information about filling a ProDataSet object, see *OpenEdge Development: ProDataSets*.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

If the AVM encounters an error, it sets the value of the ERROR attribute to TRUE for the associated ProDataSet object handle and Temp-table object handle.

**See also:** ADD-RELATION( ) method, ATTACH-DATA-SOURCE( ) method, BATCH-SIZE attribute, CREATE DATASET statement, CREATE DATA-SOURCE statement, DEFINE DATASET statement, DEFINE DATA-SOURCE statement, FILL events, FILL-MODE attribute, FILL-WHERE-STRING attribute, LAST-BATCH attribute, NEXT-ROWID
FILLED attribute

Indicates if the background color of a rectangle is set to a certain value.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** RECTANGLE widget

If the value of the FILLED attribute is TRUE, the background color of the rectangle depends on the value of the BGCOLOR attribute (for graphical interfaces) or the value of the DCOLOR attribute (for character interfaces). The default value of FILLED is TRUE.

FILL-MODE attribute

Specifies the mode in which the FILL( ) method fills a ProDataSet member buffer. The default mode is MERGE.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** Buffer object handle

Table 81 lists the FILL( ) method modes.

<table>
<thead>
<tr>
<th>When the mode is . . .</th>
<th>The FILL( ) method . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPEND</td>
<td>Fills the table by adding new records on top of existing records in the table, without performing any record comparisons. If this creates duplicate records, the AVM generates a run-time error and you must manage the duplicate records. If you are certain there are no duplicate records, an APPEND is more efficient than a MERGE.</td>
</tr>
<tr>
<td>EMPTY</td>
<td>Empties the table before the FILL operation begins.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Fills the table by merging new records with existing records in the table. The FILL( ) method checks each record to ensure there are no duplicate records (based on the table’s unique primary index). If the FILL( ) method finds a record with a duplicate key, it does not replace the record because the record might have dependent records elsewhere in the ProDataSet. In this case, the AVM does not generate a run-time error. Thus, you cannot use this mode to refresh existing records.</td>
</tr>
</tbody>
</table>
**FILL-WHERE-STRING attribute**

The current WHERE expression for a data-source query, beginning with the keyword WHERE, and not including the prior FOR EACH phrase of an OPEN QUERY statement.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Data-source object handle

You can use this attribute to override the existing WHERE expression in the query for the data-source object during a FILL( ) operation. The default is the Unknown value (?).

**Notes:** You can also modify the query on an associated data-relation using the WHERE-STRING attribute.

The NAME attribute of the Temp-table object handle is writeable for dynamic and AVM-generated temp-tables. You might need to update a FILL-WHERE-STRING that references a renamed temp-table with new strings using the new table name.

**See also:** DEFINE DATA-SOURCE statement, FILL( ) method, WHERE-STRING attribute

---

### Table 81: FILL( ) method modes

<table>
<thead>
<tr>
<th>When the mode is...</th>
<th>The FILL( ) method...</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO-FILL</td>
<td>Does not perform the FILL operation on the table.</td>
</tr>
<tr>
<td>REPLACE</td>
<td>Fills the table by replacing existing records in the table. The FILL( ) method checks each record to determine whether or not it exists in the table (based on the table’s unique primary index). If the record exists in the table, the FILL( ) method replaces it. If the record does not exist, the FILL( ) method creates a new record. The BEFORE-ROW-FILL event handler is run after the original ProDataSet row is copied into the ProDataSet buffer. A REPLACE is less efficient than an APPEND or a MERGE.</td>
</tr>
</tbody>
</table>

---

**FIND-BY-ROWID( ) method**

Locates the record with the rowid you specify, then moves the record into the buffer.
**Return type:** LOGICAL  
**Applies to:** Buffer object handle

### Syntax

```plaintext
FIND-BY-ROWID ( rowid 
    [ , 
    { SHARE-LOCK | EXCLUSIVE-LOCK | NO-LOCK } 
    [ , NO-WAIT ] 
    ] )
```

*rowid*

An expression of type ROWID that represents the rowid of the desired record.

**SHARE-LOCK | EXCLUSIVE-LOCK | NO-LOCK**

The type of lock that the AVM places on the record, if found. The default is SHARE-LOCK.

---

**Note:** For more information on record locks, see *OpenEdge Getting Started: ABL Essentials.*

---

**NO-WAIT**

Causes FIND-BY-ROWID to return FALSE immediately if another user has a lock on the desired record and FIND-BY-ROWID specifies a locking option other than NO-LOCK.

---

**Note:** To determine whether another user has a lock on the desired record, use the LOCKED attribute of the buffer object.

---

The FIND-BY-ROWID method returns TRUE if it finds the record, and FALSE if it does not.

The following is an example:

```plaintext
DEFINE VARIABLE bh AS HANDLE NO-UNDO.  
DEFINE VARIABLE r  AS ROWID NO-UNDO.  

r = ... /* ROWID from some parameter */  
bh = BUFFER CUSTOMER:HANDLE.  
bh:FIND-BY-ROWID(r).
```

---

**Note:** The FIND-BY-ROWID method corresponds to a FIND statement of the form FIND buffer WHERE ROWID (buffer) = rowid ... etc. That is, triggers are honored, and the default lock mode is SHARE-LOCK. One difference, however, is that the FIND-BY-ROWID method does not raise an error if it cannot find the record.
FIND-CURRENT( ) method

Changes the lock mode of a record in a buffer.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle  

**Syntax**

```
FIND-CURRENT ( [ lockmode [ , wait-mode ] ] )
```

**lockmode**

An integer expression evaluating to one of the following constants: SHARE-LOCK, EXCLUSIVE-LOCK, or NO-LOCK. You can assign any of these constants to an integer variable. For example, mylock = NO-LOCK. The default is SHARE-LOCK.

**waitmode**

An integer expression evaluating to one of the following: NO-WAIT, 0, or the Unknown value (?). You can assign NO-WAIT to an integer variable. For example, mywait = NO-WAIT.

The default is to wait.

The following shows an example of the FIND-CURRENT method:

```
DEFINE VARIABLE bh AS HANDLE NO-UNDO.
bh = BUFFER Customer:HANDLE.
DO TRANSACTION:
  bh:FIND-CURRENT(EXCLUSIVE-LOCK).
END.
```

If the change in lock status succeeds, the method returns TRUE, otherwise it returns FALSE.

If the lock change fails, a message displays. You can suppress the message using NO-ERROR on the statement containing the method.

Executing the FIND-CURRENT method resets the CURRENT-CHANGED attribute. If the record in the database changes between the time the original record was found and the FIND-CURRENT executes, the CURRENT-CHANGED attribute returns TRUE. If the record does not change, then the CURRENT-CHANGED attribute returns FALSE.
FIND-FIRST( ) method

Gets a single record. This method lets a user get the first record that satisfies the predicate expression.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

**Syntax**

```
FIND-FIRST (predicate-expression [, lockmode [, wait-mode ]] )
```

**predicate-expression**

A character expression that evaluates to the following syntax:

**Syntax**

```
[ WHERE [ logical-expression ] ] [ USE-INDEX index-name ]
```

Once evaluated, *predicate-expression* can contain only constants and unabbreviated references to fields from the buffer.

The *predicate-expression* itself can be built using a concatenation of character expressions.

**lockmode**

An integer expression evaluating to one of the following constants: SHARE-LOCK, EXCLUSIVE-LOCK, or NO-LOCK. You can assign any of these constants to an integer variable. For example, mylock = NO-LOCK.

The default is SHARE-LOCK.

**wait-mode**

An integer expression evaluating to one of the following: NO-WAIT, 0, or the Unknown value (?). You can assign NO-WAIT to an integer variable. For example, mywait = NO-WAIT. The default is to wait.

The following shows some examples of FIND-FIRST method:
FIND-LAST( ) method

Gets a single record. This method lets a user get the last record that satisfies the predicate expression.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

**Syntax**

```
FIND-LAST ( predicate-expression [, lockmode [, wait-mode ] ] )
```

**predicate-expression**

A character expression that evaluates to the following syntax:

**Syntax**

```
[ WHERE [ logical-expression ] ] [ USE-INDEX index-name ]
```

Once evaluated, *predicate-expression* can contain only constants and unabbreviated references to fields from the buffer.

The *predicate-expression* itself can be built using a concatenation of character expressions.

**lockmode**

An integer expression evaluating to one of the following constants: SHARE-LOCK, EXCLUSIVE-LOCK, or NO-LOCK. You can assign any of these constants to an integer variable. For example, `mylock = NO-LOCK`.

---

```
DEFINE VARIABLE bh AS HANDLE NO-UNDO.
DEFINE VARIABLE myname AS CHARACTER NO-UNDO.

bh = BUFFER Customer:HANDLE.

DO TRANSACTION:
    bh:FIND-FIRST("", EXCLUSIVE-LOCK).
END.

bh:FIND-FIRST("WHERE Customer.Name = " + QUOTER(myname), NO-LOCK).
```
The default is SHARE-LOCK.

wait-mode

An integer expression evaluating to one of the following: NO-WAIT, 0, or the Unknown value (?). You can assign NO-WAIT to an integer variable. For example, mywait = NO-WAIT. The default is to wait.

The following shows some examples of the FIND-LAST method:

```
DEFINE VARIABLE bh AS HANDLE NO-UNDO.
bh = BUFFER Customer:HANDLE.
bh:FIND-LAST("WHERE Customer.Balance > 0 use-index name").
bh:FIND-LAST("WHERE Customer.CustNum > 5 AND Customer.Address < 'z'").
```

If FIND-LAST succeeds, it returns TRUE, otherwise it returns FALSE.

If FIND-LAST fails, it does not raise an error but displays an error message. You can suppress the message using NO-ERROR on the statement containing the method.

See also: FIND-CURRENT( ) method, FIND-FIRST( ) method, FIND-UNIQUE( ) method, FIND statement

FIND-UNIQUE( ) method

Gets a single record. This method lets a user get a unique record that satisfies the predicate expression.

Return type: LOGICAL
Applies to: Buffer object handle

Syntax

```
FIND-UNIQUE ( predicate-expression [ , lockmode [ , wait-mode ] ] )
```

predicate-expression

A character expression that evaluates to the following syntax:

```
[ WHERE [ logical-expression ] ] [ USE-INDEX index-name ]
```

Once evaluated, predicate-expression can contain only constants and unabbreviated references to fields from the buffer. The predicate-expression itself can be built using a concatenation of character expressions.
**lockmode**

An integer expression evaluating to one of the following constants: SHARE-LOCK, EXCLUSIVE-LOCK, or NO-LOCK. You can assign NO-LOCK to an integer variable. For example, mylock = NO-LOCK.

The default is SHARE-LOCK.

**waitmode**

An integer expression evaluating to one of the following: NO-WAIT, 0, or the Unknown value (?). The default is to wait.

You can assign NO-WAIT to an integer variable. For example, mywait = NO-WAIT.

The following shows some examples of the FIND-UNIQUE method:

```plaintext
DEFINE VARIABLE bh AS HANDLE NO-UNDO.
DEFINE VARIABLE myname AS CHARACTER NO-UNDO.

bh = BUFFER Customer:HANDLE.

bh:FIND-UNIQUE("WHERE Customer.Custnum < 3 AND Customer.Name = 'lift line skiing'").

bh:FIND-UNIQUE("WHERE Customer.CustNum = 30").

bh:FIND-UNIQUE("WHERE Customer.Name = " + QUOTER(myname). MESSAGE bh:AMBIGUOUS.
```

If FIND-UNIQUE succeeds, it returns TRUE, otherwise it returns FALSE.

If FIND-UNIQUE fails, a message displays. You can suppress this message using NO-ERROR on the statement containing the method.

If more than one record satisfies the predicate expression, then the AMBIGUOUS attribute is set to TRUE.

**See also:** FIND-FIRST() method, FIND-CURRENT() method, FIND-LAST() method, FIND statement

---

**FIRST-ASYNC-REQUEST attribute**

Returns the first entry in the list of all current asynchronous request handles for the specified AppServer or Web service that have been created in the current session.

**Data type:** HANDLE

**Access:** Readable

**Applies to:** Server object handle

If there are no asynchronous request handles for the specified server, FIRST-ASYNC-REQUEST returns the Unknown value (?).
FIRST-BUFFER attribute

Returns the handle for the first dynamic buffer in the first table containing a dynamic buffer. The table may be either a temp-table or a connected database, in that order. If no dynamic temp-table or database buffers exist in the session, it returns the Unknown value (?)..

**Note:** Only dynamic buffers created with the CREATE BUFFER statement are chained on the SESSION system handle.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** SESSION system handle  

There is no LAST-BUFFER attribute associated with the SESSION handle since the chain is one-directional.

FIRST-CHILD attribute

The handle of the first widget created in the container widget or the current session.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** DIALOG-BOX widget, FIELD-GROUP widget, FRAME widget, MENU widget, SUB-MENU widget, WINDOW widget, SESSION system handle

You can use the FIRST-CHILD attribute to find the first entry in a list of all frames and dialog boxes in a window, all field groups in a frame or dialog box, all widgets in a field group, all menu items in a menu or submenu, or all windows in an ABL session (SESSION system handle). After finding the first entry, you can find the remaining entries in the list by using each widget’s NEXT-SIBLING attribute.

FIRST-COLUMN attribute

A handle to the first column in a browse widget, regardless of the value of its READ-ONLY attribute or its VISIBLE attribute.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** BROWSE widget  

After finding the first column, accessing the NEXT-COLUMN attribute of the current column allows you to walk through the browse columns.
**FIRST-DATASET attribute**

A handle to the first dynamic ProDataSet object created in the current ABL session.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:** SESSION system handle

After finding the first entry, you can find the remaining entries in the list by using the NEXT-SIBLING attribute for each dynamic ProDataSet object. Use the NEXT-SIBLING attribute to get the next entry in the list of ProDataSet object handles created in the current ABL session.

**FIRST-DATA-SOURCE attribute**

A handle to the first dynamic Data-source object created in the current ABL session.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:** SESSION system handle

Use the NEXT-SIBLING attribute to get the next entry in the chain of dynamic Data-source object handles created in the current ABL session.

**FIRST-FORM attribute**

*(Windows only; GUI for .NET only)*

The object reference for the first .NET form or ABL FormProxy object (Progress.GUI.FormProxy) in the list of all valid form objects created in the current ABL session.

- **Data type:** Progress.Windows.IForm
- **Access:** Readable
- **Applies to:** SESSION system handle

Once you get the first object reference in the list, you can use the NextForm property in the Progress.Windows.IForm interface to get the next entry in the list of form object references.

**Note:** To obtain the first class-based object in the list of all valid ABL and .NET objects created in the current ABL session, use the FIRST-OBJECT attribute.
FIRST-OBJECT attribute

The object reference for the first class instance in the list of all valid ABL and .NET class instances created in the current ABL session. If there are no class instances in the current session, this attribute returns the Unknown value (?).

Data type: Progress.Lang.Object
Access: Readable
Applies to: SESSION system handle

Once you get the first object reference in the list, you can use the NEXT-SIBLING property in the Progress.Lang.Object class to get the next entry in the list of ABL and .NET object references.

There are two points worth noting about this attribute with garbage collection enabled:

- The object references maintained by the FIRST-OBJECT attribute and the NEXT-SIBLING property do not count as references for garbage collection. That is, if a class instance is referenced only on the session object chain, it is available for automatic garbage collection.

- When an ABL object that inherits from a .NET object is on the session object chain, it can have circular references that prevent it from being deleted (as with pure ABL objects). When there are no more ABL references to such an ABL-derived .NET object, the object is removed from the object chain, but may still be instantiated because of references to it from .NET. If the application re-obtains a reference to the object in ABL by getting it from .NET, the reference is again placed on the object chain.

Note: To obtain the first .NET form or ABL FormProxy object in the list of all valid form objects created in the current ABL session, use the FIRST-FORM attribute.

See also: FIRST-FORM attribute, LAST-OBJECT attribute, NEXT-SIBLING property, Progress.Lang.Object class

FIRST-OF() method

Returns TRUE if the current iteration of the query predicate FOR EACH . . . BREAK BY . . . is the first iteration for a new break group.

Return type: LOGICAL
Applies to: Query object handle

Syntax

FIRST-OF( level )
**FIRST-PROCEDURE attribute**

For AppServer, returns the first entry in the list of remote persistent procedures running on the connected AppServer. For Web services, returns the first entry in the list of procedure objects associated with the Web service.

**Data type:** HANDLE

**Access:** Readable

**Applies to:** Server object handle, SESSION system handle

If the current session has no active persistent procedures or the AppServer has no active remote persistent procedures, FIRST-PROCEDURE has the Unknown value (?). To find the next persistent procedure given the first, use the NEXT-SIBLING attribute of the procedure handle.

For information on creating persistent procedures, see the RUN statement reference entry. For more information on the AppServer, see *OpenEdge Application Server: Developing AppServer Applications*. To check a handle for validity, use the VALID-HANDLE function.

---

**FIRST-QUERY attribute**

A handle to the first dynamic query created in the current ABL session.
First-server attribute

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

Use the NEXT-SIBLING attribute to get the next entry in the chain of dynamic query handles created in the current ABL session. The chain of dynamic query handles includes all automatically generated queries, such as those created for data-relation objects.

First-server attribute

A handle to the first entry in the list of server handles of the current ABL session. This includes both AppServer server objects and Web service server objects.

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

The handle associated with the first entry in the list of all server handles created in the current session. If the current session has no server handles, FIRST-SERVER has the Unknown value (?). For more information on server handles, see the Server object handle reference entry.

First-server-socket attribute

A handle to the first entry in the list of all valid server socket handles created in the current session. If there are no server socket handles in this session, FIRST-SERVER-socket returns the Unknown value (?).

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

First-socket attribute

A handle to the first entry in the list of all valid socket handles created in the current session. If there are no socket handles in this session, FIRST-SOCKET returns the Unknown value (?).

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

First-tab-item attribute

The first widget in the tab order of a field group.
**FIT-LAST-COLUMN attribute**

**Data type:** HANDLE  
**Access:** Readable/Writeable  
** Applies to:** FIELD-GROUP widget

When you set this attribute, the assigned widget is moved to the first tab position, preceding the widget that was previously at this position. Other widgets in the field group maintain their same relative tab positions.

To set the attribute, you must assign it the handle of a field-level widget or frame that can receive focus from a TAB event and that is also a child of the field group to which the attribute applies. If the FIRST-TAB-ITEM attribute is not set (that is, is the Unknown value (?)), the default first tab position goes to the widget identified by the FIRST-CHILD attribute of the field group.

For more information on how frames owned by a field group participate in the tab order of that field group, see the FRAME widget reference entry.

**Note:** Any tab reordering that you do with this attribute can be reset by a subsequent ENABLE statement unless you define the frame that owns the field group with the KEEP-TAB-ORDER option. For more information, see the ENABLE statement and Frame phrase reference entries.

---

**FIT-LAST-COLUMN attribute**  
**(Graphical interfaces only)**

Allows the browse to be displayed so that there is no empty space to the right and no horizontal scroll bar by potentially widening or shrinking the last browse column’s width.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
** Applies to:** BROWSE widget

When this attribute is specified, and the last browse column can be fully or partially displayed in the browse’s viewport, then the last browse column’s width is adjusted so that it fits within the viewport with no empty space to its right and no horizontal scroll bar.

If the last browse column is fully contained in the viewport with empty space to its right, it grows so that its right edge is adjacent to the vertical scroll bar.

If the last browse column extends outside the viewport, it shrinks so its right edge is adjacent to the vertical scroll bar and the horizontal scroll bar is not needed.

The default value is FALSE.

**Note:** The FIT-LAST-COLUMN attribute performs the same function as the EXPANDABLE attribute. Progress Software Corporation recommends that you use the FIT-LAST-COLUMN attribute instead of the EXPANDABLE attribute. This recommendation includes replacing EXPANDABLE with FIT-LAST-COLUMN in your current code.

The following shows the DEFINE BROWSE statement syntax with FIT-LAST-COLUMN specified:
The MIN-COLUMN-WIDTH attribute affects the FIT-LAST-COLUMN attribute. As a result, if FIT-LAST-COLUMN is set to TRUE, the last browse column is resized to fit within the viewport only if its width is no smaller than the minimum width. To specify the minimum size that the last browse column’s width can be reduced to, use the MIN-COLUMN-WIDTH-PIXELS or MIN-COLUMN-WIDTH-CHARS attribute. See MIN-COLUMN-WIDTH-PIXELS attribute and MIN-COLUMN-WIDTH-CHARS attribute for more information.

FIT-LAST-COLUMN and NO-EMPTY-SPACE are mutually exclusive. If both are specified in the DEFINE BROWSE statement, the compiler displays an error message. If one attribute is set to TRUE while the other attribute is already TRUE, a warning message displays at run time.

FIT-LAST-COLUMN is primarily intended for use in the initial layout of a static browse. It is most useful when laying out a browse with a specified width when you have only a few browse columns and you want to fully use the available space in your viewport.

If the FIT-LAST-COLUMN attribute is set to TRUE, and, subsequently, any browse column’s width is changed or the browse’s width is changed, then the last browse column’s width might be adjusted so that it fits within the viewport with no empty space and no horizontal scroll bar.

When the last browse column’s width is set at run time after the browse is realized, then FIT-LAST-COLUMN is ignored.

If the FIT-LAST-COLUMN attribute is set to FALSE, the last browse column’s width remains the same and is never changed by ABL.

The FIT-LAST-COLUMN attribute and the EXPANDABLE attribute have the same behavior. Therefore, if you specify the Expand Browse (-expandbrow) startup parameter at startup, the FIT-LAST-COLUMN attribute is set to TRUE for each browse in that session.

See also: DEFINE BROWSE statement

**FLAT-BUTTON attribute**
(Windows only; Graphical interfaces only)

Indicates whether a button is two-dimensional until the mouse passes over it, at which time, a 3D border appears.

**Data type:** LOGICAL

**Access:** Readable/Writable

**Applies to:** BUTTON widget

The FLAT-BUTTON attribute must be set before the button is realized. The default value is FALSE.
FOCUSED-ROW attribute

The 1-based index or position of the focused row in the viewport.

- **Data type:** INTEGER
- **Access:** Readable
- **Applies to:** BROWSE widget

FOCUSED-ROW-SELECTED attribute

Indicates whether the row that has focus is selected.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** BROWSE widget

If the row that has focus is selected, FOCUSED-ROW-SELECTED is TRUE. Otherwise, it is FALSE.

FONT attribute

(Graphical interfaces only)

The number of the font of a widget.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget (browse, column, and cell), BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, LITERAL widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

The font number represents an entry in the font table maintained by the FONT-TABLE handle.

For a browse cell, it specifies the font of a specific cell in the view port. You can set this font only as the cell appears in the view port during a ROW-DISPLAY event.

For browsers, this attribute applies only to fill-in and combo-box browse columns.

Setting the FLAT-BUTTON attribute to TRUE forces the NO-FOCUS attribute to TRUE because the FLAT-BUTTON attribute only works with the NO-FOCUS attribute. Similarly, setting the NO-FOCUS attribute to FALSE forces the FLAT-BUTTON attribute to FALSE.

The mnemonic key (**ALT** accelerator) for a widget will not work if the NO-FOCUS attribute is TRUE because this removes the widget from the tab order. Also, because the widget is not in the tab order, pressing **TAB** will not change focus from the widget.
**FOREGROUND attribute**

Indicates whether the field group is a foreground or a background field group.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** FIELD-GROUP widget

If the FOREGROUND attribute is TRUE, the field group is a foreground (data iteration) group. If FOREGROUND is FALSE, the field group is the background group for the frame.

**FOREIGN-KEY-HIDDEN attribute**

Specifies whether to hide foreign key fields in the child records of a nested data-relation in a ProDataset.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** Data-relation object handle

This setting is only valid if the NESTED attribute is also TRUE.

When working with large ProDataSets, omitting foreign keys in nested child records can yield smaller XML documents, more efficient network transfers, and performance gains with the READ-XML( ) and WRITE-XML( ) methods.

Care must be taken when deciding to use this feature. The READ-XML( ) method automatically populates foreign keys in nested child records with the value in the outer parent record when the foreign key is omitted from the XML document. Unless you are sure that the receiver of the XML document will do the same, you should not use this option in your nested data-relations.

For example, while .NET can read this XML document and populate an ADO .NET DataSet, it will create rows in the child DataTable with a null value for the foreign key field.

**See also:** NESTED attribute

**FORM-INPUT attribute**

Returns raw HTTP form input that is less than 32K in size. Do not access this attribute.
**FORM-LONG-INPUT attribute**

Data type: CHARACTER  
Access: Readable  
Applies to: WEB-CONTEXT system handle

**FORM-LONG-INPUT attribute**

Returns raw HTTP form input that is greater than 32K in size. The AVM performs no conversion on the data. Do not access this attribute.

Data type: MEMPTR  
Access: Readable  
Applies to: WEB-CONTEXT system handle

**FORMAT attribute**

The text format of a widget or browse-cell.

Data type: CHARACTER  
Access: Readable/Writeable  
Applies to: BROWSE widget (cell), Buffer-field object handle, COMBO-BOX widget, FILL-IN widget, TEXT widget, TOGGLE-BOX widget

For DROP-DOWN-LIST combo-boxes, if you set this attribute with items in the drop-down list, all items are converted to the new format. This attribute is ignored for SIMPLE and DROP-DOWN combo-boxes.

For combo boxes whose entries consist of label-value pairs, the AVM converts all values to the new format.

For browses, this attribute applies only to fill-in and combo-box browse columns.

For browses in Windows, if you modify the FORMAT attribute of a browse-cell, its format changes, but its size does not.

For buffer-fields, the value of the FORMAT attribute does not affect the ABL user interface anywhere. Rather, it controls the output of the STRING-VALUE attribute, and lets users explicitly format non-ABL user interfaces.

**Note:** When the AUTO-RESIZE attribute is TRUE, the AVM resizes combo box and fill-in field widgets with run-time changes to the FORMAT attribute.

**FORMATTED attribute**

Determines the format of XML output from a SAX-writer object.
### FORWARD-ONLY attribute

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SAX-writer object handle

The default value is FALSE.

TRUE indicates that the SAX-writer should format the document with additional white space, carriage returns, and line feeds, so that the elements display in a hierarchical manner.

FALSE indicates the SAX-writer should create an optimized document that includes no extra white space.

You can read this attribute at all times, but you can only write to it when the WRITE-STATUS is either SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. That is, you can only change the attribute when the SAX-writer is not writing, otherwise the call fails and generate an error message.

### FORWARD-ONLY attribute

Lets you avoid building result-lists for static and dynamic queries.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Query object handle

Set to TRUE to avoid building result-lists for queries. Set to FALSE to build result-lists for queries. The default is FALSE.

When TRUE, you cannot use the GET PREV, GET LAST, REPOSITION, or BROWSE methods or statements with these queries. If you do, the AVM generates an error. You can use the GET-FIRST( ) method and GET FIRST statement only on newly opened queries, and you can use the GET NEXT statement and GET-NEXT( ) method freely.

If you set FORWARD-ONLY to TRUE, and you open a query with preselect or sort, the AVM still builds a result-list in order to resolve the query. You cannot set FORWARD-ONLY while a query is open or being browsed.

Setting FORWARD-ONLY to TRUE can improve the performance of operations on queries.

### FRAGMENT attribute

Specifies if the output of a SAX-writer object is a complete document or a fragment.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SAX-writer object handle

The default value is FALSE.
FRAME attribute

The handle of the frame that contains the widget.

**Data type:** HANDLE  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

This attribute is writeable only for static frames and all dynamic widgets. You can set this attribute for a static frame only before the widget is realized.

FRAME-COL attribute

The decimal column position, in character units, of the left edge of the widget relative to the upper left corner of the frame that contains the widget.

**Data type:** DECIMAL  
**Access:** Readable  
**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

FRAME-NAME attribute

The name of the frame that contains the widget.

TRUE indicates that the writer should not include the XML declaration or require a root node. This behavior allows the developer to create XML fragments which can be used to create larger documents. For example, one SAX-writer object’s document fragment LONGCHAR could be used as the parameter of WRITE-FRAGMENT for another SAX-writer.

FALSE indicates the SAX-writer should create a complete XML document with the XML declaration and root node.

You can read this attribute at all times, but you can only write to it when the WRITE-STATUS is either SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. That is, the attribute can only be changed when the SAX-writer is not writing, otherwise it fails and generates an error message.
**FRAME-ROW attribute**

The decimal row position, in character units, of the top edge of the widget relative to the upper left corner of the frame that contains the widget.

- **Data type:** DECIMAL
- **Access:** Readable
- **Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

If the parent frame is a down frame with multiple occurrences, the FRAME-ROW attribute regards the original occurrence as the parent, not the current occurrence.

**FRAME-SPACING attribute**

The number of display units between frames in a window. In graphical interfaces the display units are pixels. In character interfaces the display units are character cells.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** SESSION system handle

By default, the value for FRAME-SPACING is the height of one row in the default system font. In character interfaces, this is the character cell height. In graphical interfaces, this is the number of pixels returned by the PIXELS-PER-ROW attribute.

**FRAME-X attribute**

The location of the left edge of the widget relative to the upper left corner of the frame that contains the widget.
FRAME-Y attribute

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

In character mode, this attribute returns the widget location in row column units. In graphical interfaces, this attribute returns pixels.

---

FRAME-Y attribute

The location of the top edge of the widget relative to the upper left corner of the frame that contains the widget.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

In character mode, this attribute returns the widget location in row column units. In graphical interfaces, this attribute returns pixels.

---

FREQUENCY attribute

Indicates the incremental display of the TIC-MARKS attribute. It is used exclusively with the TIC-MARKS attribute.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** SLIDER widget

For example, if you set FREQUENCY to 5, a tic mark appears in every fifth position along the length of the slider.

---

FULL-HEIGHT-CHARS attribute

The maximum internal height of the window, in character units.
FULL-HEIGHT-PIXELS attribute

Data type: DECIMAL
Access: Readable
Applies to: WINDOW widget

The maximum internal height of a window is the height of the screen display minus the vertical spacing required to display the border, title bar, menu bar, message area, and status area of the window.

The value of this attribute is the Unknown value (?) until the window is realized.

FULL-HEIGHT-PIXELS attribute

The maximum internal height of the window, in pixel units.

Data type: INTEGER
Access: Readable
Applies to: WINDOW widget

The maximum internal height of a window is the height of the screen display minus the vertical spacing required to display the border, title bar, menu bar, message area, and status area of the window.

The value of this attribute is the Unknown value (?) until the window is realized.

FULL-PATHNAME attribute

The absolute pathname of the file specified in the FILE-NAME attribute.

Data type: CHARACTER
Access: Readable
Applies to: FILE-INFO system handle

FULL-WIDTH-CHARS attribute

The maximum internal width of the window, in character units.

Data type: DECIMAL
Access: Readable
Applies to: WINDOW widget

The maximum internal width of a window is the width of the screen display minus the horizontal spacing required to display the border of the window.

The value of this attribute is the Unknown value (?) until the window is realized.
FULL-WIDTH-PIXELS attribute

The maximum internal width of the window, in pixel units.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** WINDOW widget

The maximum internal width of a window is the width of the screen display minus the horizontal spacing required to display the border of the window.

The value of this attribute is the Unknown value (?) until the window is realized.

FUNCTION attribute

The names of high-level events based on the EVENT-TYPE attribute value.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** LAST-EVENT system handle

For EVENT-TYPE = "KEYPRESS", this attribute returns key functions, such as "RETURN". For EVENT-TYPE = "MOUSE", this attribute returns high-level events for both portable and three-button event types, such as "MOUSE-SELECT-CLICK" (portable) or "LEFT-MOUSE-CLICK" (three-button). For EVENT-TYPE = "PROGRESS", this attribute returns high-level widget and direct manipulation events, such as "CHOOSE" or "SELECTION".

GET-ATTRIBUTE( ) method

Returns the value of the specified attribute of an element referred to by an XML node reference.

**Return type:** LOGICAL  
**Applies to:** X-noderef object handle

**Syntax**

```
GET-ATTRIBUTE( name )
```

**name**

The attribute name whose value is desired. Attribute names are defined within the element tag. If using a DTD, you can define attributes with the "IMPLIED" property and those attributes will appear in the DOM structure.

If hNoderef is an element node with various attributes, and anames and bname are character program variables, the following example demonstrates listing all the attributes of the node:
GET-ATTRIBUTE-NODE( ) method

Returns the XML ATTRIBUTE node with the specified name.

**Return type:** LOGICAL

**Applies to:** X-noderef object handle

**Syntax**

```
GET-ATTRIBUTE-NODE( attr-node-handle, name )
```

<table>
<thead>
<tr>
<th>attr-node-handle</th>
</tr>
</thead>
<tbody>
<tr>
<td>A valid X-noderef handle to use for the XML ATTRIBUTE node.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>A character expression representing the name of the XML ATTRIBUTE node. For a namespace-aware ATTRIBUTE node, you must qualify the node name with a prefix including a colon (for example, prefix:node-name).</td>
</tr>
</tbody>
</table>

GET-BINARY-DATA( ) method

Returns a MEMPTR containing the binary data in the file specified in the form field. The AVM sets the size of the MEMPTR to match the size of the file. This method is called by the get-binary-data WebSpeed API function. Intended for internal use only.

**Return type:** MEMPTR

**Applies to:** WEB-CONTEXT system handle

**Syntax**

```
GET-BINARY-DATA( INPUT field-name )
```

<table>
<thead>
<tr>
<th>field-name</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name of the form field containing the name of the file posted in the web request received by the WebSpeed Agent.</td>
</tr>
</tbody>
</table>

If the specified field is not part of the form, or the field is not of type ‘file’, the AVM returns the Unknown value (?) and displays an error message. You can suppress this message by using NO-ERROR on the statement containing the method.
GET-BLUE-VALUE( ) method
(Graphical interfaces only)

Returns the blue component of an entry in the color table.

**Return type:** INTEGER

**Applies to:** COLOR-TABLE system handle

**Syntax**

```
GET-BLUE-VALUE ( index )
```

*index*  
An integer expression that specifies an entry in the color table.

---

GET-BROWSE-COLUMN( ) method

Returns the handle for the requested browse column.

**Return type:** HANDLE

**Applies to:** BROWSE widget

**Syntax**

```
GET-BROWSE-COLUMN( col-index )
```

*col-index*  
An integer value specifying the 1-based index into the browse column list.

---

GET-BUFFER-HANDLE( ) method

Gets the handle to a particular buffer of a query or ProDataSet object.

**Return type:** HANDLE

**Applies to:** ProDataSet object handle, Query object handle

**Syntax**

```
GET-BUFFER-HANDLE ( buffer-sequence-number | buffer-name )
```

*buffer-sequence-number*  
An integer that represents the sequence number of the desired buffer.

**Note:** Sequence numbers for buffers of a query start at one, where one represents the top level and subsequent numbers represent lower levels of join, if any.
buffer-name

A CHARACTER expression that evaluates to the name of a buffer in the query or ProDataSet object.

If the buffer cannot be found, this attribute returns the Unknown value (?).

GET-BYTES-AVAILABLE( ) method

Indicates the number of bytes available for reading from the socket.

Return type: INTEGER
Applies to: Socket object handle

Syntax

GET-BYTES-AVAILABLE( )

GET-CALLBACK-PROC-CONTEXT( ) method

Returns the handle of the procedure that contains the internal procedure associated with the ABL callback for the specified event.

Return type: HANDLE
Applies to: Buffer object handle, ProDataSet object handle, Query object handle

Syntax

GET-CALLBACK-PROC-CONTEXT( event-name )

event-name

The name of a defined event.

If the object does not have a callback procedure for the specified event, this method returns the Unknown value (?).

Use the SET-CALLBACK-PROCEDURE( ) method to associate an internal procedure with a callback for an object.

For more information on events, see the “Handle-based Object Events Reference” section on page 1827.

See also: APPLY-CALLBACK( ) method, GET-CALLBACK-PROC-NAME( ) method, SET-CALLBACK-PROCEDURE( ) method

GET-CALLBACK-PROC-NAME( ) method

Returns the name of the internal procedure associated with the ABL callback for the specified event.
GET-CGI-LIST( ) method

**Return type:** CHARACTER  
**Applies to:** Buffer object handle, ProDataSet object handle, Query object handle

**Syntax**

```plaintext
GET-CALLBACK-PROC-NAME( event-name )
```

*event-name*

The name of a defined event.

If the object does not have a callback procedure for the specified event, this method returns the Unknown value (?).

Use the SET-CALLBACK-PROCEDURE( ) method to associate an internal procedure with a callback for an object.

For more information on events, see the “Handle-based Object Events Reference” section on page 1827.

**See also:** APPLY-CALLBACK( ) method, GET-CALLBACK-PROC-CONTEXT( ) method, SET-CALLBACK-PROCEDURE( ) method

---

**GET-CGI-LIST( ) method**

Gets the list of CGI environment variables. This method is called by the *get-cgi* WebSpeed API function. Intended for internal use only.

**Return type:** CHARACTER  
**Applies to:** WEB-CONTEXT system handle

---

**GET-CGI-VALUE( ) method**

Gets the value of a specified CGI environment variable. This method is called by the *get-cgi* WebSpeed API function. Intended for internal use only.

**Return type:** CHARACTER  
**Applies to:** WEB-CONTEXT system handle

---

**GET-CGI-LONG-VALUE( ) method**

Returns a LONGCHAR value in either the code page specified in the HTML-CHARSET attribute, if that code page is valid for a LONGCHAR, or -cpinternal. Otherwise, it returns the Unknown value (?) and displays an error message. You can suppress this message by using NO-ERROR on the statement containing the method. This method is called by the *get-cgi-long* and *get-long-value* WebSpeed API functions. Intended for internal use only.
GET-CHANGES( ) method

Loads an empty ProDataSet object with changed rows from either a single temp-table or all temp-tables in another ProDataSet object.

Return type: LOGICAL
Applies to: Buffer object handle, ProDataSet object handle

Syntax

\[ \text{change-handle:GET-CHANGES(original-handle [, get-parent-mode ])} \]

change-handle

A handle to the ProDataSet object or ProDataSet temp-table buffer to receive the changed rows.

original-handle

A handle to the source ProDataSet object or ProDataSet temp-table buffer that contains the changed rows.

get-parent-mode

An optional logical expression where TRUE indicates that the AVM get changed rows in a get-parent mode.

When TRUE, the AVM includes the parent row of each changed child row in the ProDataSet object or ProDataSet temp-table (if any). If there is more than one parent level above the changed row, the AVM includes the parent row at each level. In this case, the parent temp-tables must have a unique primary index that the AVM can use to find the corresponding rows. If a parent row has changed, the AVM copies both the before-image and after-image of the parent row. If a parent row has not changed, there will be no before-image of the parent row, and its change state (ROW-STATE) will be ROW-UNMODIFIED (0) or the Unknown value (?).

Note: When the relation mode of a parent is REPOSITION, no attempt is made to find that parent.

When FALSE, the AVM does not include parent rows. The default value is FALSE.

The ProDataSet objects associated with the change-handle and original-handle must have the same number of temp-table buffers, and the definition of the corresponding temp-tables must match (that is, in the number of columns, data types, and so on).
Once the changed rows are loaded, the AVM sets the ORIGIN-HANDLE attribute on the temp-tables in the receiving ProDataSet object to the corresponding temp-tables in the original source ProDataSet object. The AVM also sets the ORIGIN-ROWID attribute on each of the before-image table rows created in the receiving ProDataSet object to the ROWID of the corresponding before-image table row in the original source temp-table. The MERGE-CHANGES( ) method and MERGE-ROW-CHANGES( ) method uses these values to match up temp-tables and temp-table rows during a merge operation.

### GET-CHILD( ) method

Retrieves a specific child node of the current node. The first parameter must be a valid X-noderef handle and will refer to the specified child XML node if the method succeeds.

**Return type:** LOGICAL  
**Applies to:** X-document object handle, X-noderef object handle

**Syntax**

```
GET-CHILD( x-node-handle , index )
```

**x-node-handle**

A valid X-noderef handle to use as the child XML node.

**index**

An integer representing the relative number in the node-tree (1 based).

The following code fragment demonstrates getting all the child nodes from the XML node referenced by hNoderef using the GET-CHILD( ) method:

```
. . .
REPEAT jx = 1 TO hNoderef:NUM-CHILDREN:
  ok = hNoderef:GET-CHILD(hNoderefChild, jx).
  IF NOT ok THEN LEAVE.
. . .
END.
```

### GET-CHILD-RELATION( ) method

Gets the handle to a data-relation object for which the buffer is the parent.

**Return type:** HANDLE  
**Applies to:** Buffer object handle

**Syntax**

```
GET-CHILD-RELATION ( index )
```
**GET-COLUMN( ) method**

Returns the column number at which the \( n \)th message occurred during the preceding compilation.

**Return type:** INTEGER  
**Applies to:** COMPILER system handle

**Syntax**

```
GET-COLUMN ( \( n \) )
```

\( n \)

An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of a compilation message. If the \( n \)th occurrence of a compilation message did not occur, the compiler issues a warning message at runtime.

**GET-CONFIG-VALUE( ) method**

Gets the value of parameters set in the WebSpeed configuration file. This method is called by the `get-config` WebSpeed API function. Intended for internal use only.

**Return type:** CHARACTER  
**Applies to:** WEB-CONTEXT system handle

**GET-CURRENT( ) method**

Refetches the current record or records associated with the query.

**Return type:** LOGICAL  
**Applies to:** Query object handle

**Syntax**

```
GET-CURRENT ( NO-LOCK | SHARE-LOCK [ , NO-WAIT ] | EXCLUSIVE-LOCK [ , NO-WAIT ] )
```

**NO-LOCK**

Specifies that no lock is applied to the record. This applies to all buffers in a join.

**SHARE-LOCK**

Specifies that the record is share locked. This applies to all buffers in a join.
GET-DATASET-BUFFER( ) method

EXCLUSIVE-LOCK

Specifies that the record is exclusively locked. This applies to all buffers in a join.

NO-WAIT

Specifies that the method returns immediately if the record cannot be accessed because it is locked by another user. If you do not use the NO-WAIT option, the method waits until the record can be accessed. This applies to all buffers in a join. If you specify NO-WAIT and the record is locked by another user, the record is returned to you with NO-LOCK and the LOCKED function returns TRUE for the record.

GET-DATASET-BUFFER( ) method

Gets the handle to the ProDataSet object buffer associated with the Data-source object.

Return type: HANDLE
Applies to: Data-source object handle

Syntax

GET-DATASET-BUFFER( )

GET-DOCUMENT-ELEMENT( ) method

Retrieves the root element of the document. The parameter must be a valid X-noderef handle and will refer to the document’s root element if the method succeeds.

Return type: LOGICAL
Applies to: X-document object handle

Syntax

GET-DOCUMENT-ELEMENT( x-node-handle )

x-node-handle

A valid X-noderef handle to use for the root element.

The following example demonstrates the use of GET-DOCUMENT-ELEMENT if hDoc is an X-document and hRoot is an X-noderef:
**GET-DROPPED-FILE() method**

(Windows only; Graphical interfaces only)

Returns the name of the dropped file indicated by the `index` parameter.

**Return type:** CHARACTER

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

**Syntax**

```
GET-DROPPED-FILE ( index )
```

If `index` is less than 1 or greater than the number of dropped files (as indicated by NUM-DROPPED-FILES), GET-DROPPED-FILE() returns the Unknown value (?). If there is no current drag-and-drop operation, GET-DROPPED-FILE() returns the Unknown value (?).

---

**GET-DYNAMIC() method**

(Graphical interfaces only)

Returns TRUE if the entry in the color table is a dynamic color.

**Return type:** LOGICAL

**Applies to:** COLOR-TABLE system handle

**Syntax**

```
GET-DYNAMIC ( index )
```

`index`  
An integer expression that specifies an entry in the color table.
GET-ERROR-COLUMN( ) method

Returns the listing column number at which the \textit{n}th error occurred in the preceding ABL source code compilation.

This method is supported only for backward compatibility. Use the \texttt{GET-COLUMN( )} method instead.

\textbf{Return type:} INTEGER

\textbf{Applies to:} COMPILER system handle

\textbf{Syntax}

\begin{verbatim}
GET-ERROR-COLUMN ( \textit{n} )
\end{verbatim}

\textit{n}

An integer expression, from 1 to the value of the \texttt{NUM-MESSAGES} attribute, that specifies the numeric occurrence of a compilation error. If the \textit{n}th occurrence of a compilation error did not occur, this method returns the Unknown value (?)

---

GET-ERROR-ROW( ) method

Returns the listing line number at which the \textit{n}th error occurred in the preceding ABL source code compilation.

This method is supported only for backward compatibility. Use the \texttt{GET-ROW( )} method instead.

\textbf{Return type:} INTEGER

\textbf{Applies to:} COMPILER system handle

\textbf{Syntax}

\begin{verbatim}
GET-ERROR-ROW ( \textit{n} )
\end{verbatim}

\textit{n}

An integer expression, from 1 to the value of the \texttt{NUM-MESSAGES} attribute, that specifies the numeric occurrence of a compilation error.

If the \textit{n}th occurrence of a compilation error did not occur, this method returns the Unknown value (?).

---

GET-FILE-NAME( ) method

Returns the name of the source file associated with the \textit{n}th error that occurred in the preceding ABL source code compilation.
GET-FILE-OFFSET( ) method

Return type: CHARACTER
Applies to: COMPILER system handle

Syntax

GET-FILE-OFFSET ( n )

n

An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of a compilation error.

If the nth occurrence of a compilation error did not occur, this method returns the Unknown value (?).

GET-FILE-OFFSET( ) method

Returns the character offset at which the nth error occurred in the associated source file during the preceding ABL source code compilation.

Return type: INTEGER
Applies to: COMPILER system handle

Syntax

GET-FILE-OFFSET ( n )

n

An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of a compilation error.

If the nth occurrence of a compilation error did not occur, this method returns the Unknown value (?).

GET-FIRST( ) method

Moves a query object’s result list pointer to the first row.

Return type: LOGICAL
Applies to: Query object handle

Syntax

GET-FIRST ( NO-LOCK | SHARE-LOCK [, NO-WAIT ] | EXCLUSIVE-LOCK [, NO-WAIT ] )

NO-LOCK

Specifies that no lock is applied to the record. This applies to all buffers in a join. Unless explicitly specified otherwise, this is the default lock type for this method.
SHARE-LOCK

Specifies that the record is share locked. This applies to all buffers in a join.

EXCLUSIVE-LOCK

Specifies that the record is exclusively locked. This applies to all buffers in a join.

NO-WAIT

Specifies that the method returns immediately if the record cannot be accessed because it is locked by another user. If you do not use the NO-WAIT option, the method waits until the record can be accessed. This applies to all buffers in a join. If you specify NO-WAIT and the record is locked by another user, the record is returned to you with NO-LOCK and the LOCKED function returns TRUE for the record.

GET-FIRST() returns TRUE if the first record in the query is found. If the query is not open or the first record cannot be found (query is empty), the method returns FALSE. If the query object handle is invalid, the method returns the Unknown value (?).

A query that includes a BREAK BY phrase becomes a FORWARD-ONLY query. In this case you cannot use the GET-FIRST() method. If you do, the AVM raises ERROR.

GET-GREEN-VALUE( ) method
(Graphical interfaces only)

Returns the green component of an entry in the color table.

Return type: INTEGER
Applies to: COLOR-TABLE system handle

Syntax

GET-GREEN-VALUE ( index )

index

An integer expression that specifies an entry in the color table.

GET-HEADER-ENTRY( ) method

Retrieves the SOAP-header-entryref object at the given header entry index (base 1). In other words, a SOAP-header object contains a list of entries. Each entry points to an existing SOAP-header-entryref object. This method finds the SOAP-header-entryref object associated with indexed header entry and copies its handle to the header-entryref handle you provided.

Return type: LOGICAL
Applies to: SOAP-header object handle

Syntax

GET-HEADER-ENTRY( header-entryref, index )

1482
GET-INDEX-BY-NAMESPACE-NAME( ) method

Gets the 1-based index of the attribute with the given namespace name.

Return type: INTEGER

Applies to: SAX-attributes object handle

Syntax

GET-INDEX-BY-NAMESPACE-NAME( uri, localname )

uri

The namespace URI (that is, the URI to which the attribute’s prefix refers), or if the name has no namespace URI, an empty string.

localname

The local (unqualified) name of the attribute.

Returns the Unknown value (?) if no attribute’s uri-localname combination matches the combination of uri and localname.

GET-INDEX-BY-QNAME( ) method

Gets the 1-based index of the attribute with the given XML qualified name.

Return type: INTEGER

Applies to: SAX-attributes object handle

Syntax

GET-INDEX-BY-QNAME( qname )

qname

A CHARACTER expression indicating the XML qualified name of the attribute of interest.

Returns the Unknown value (?) if no attribute’s XML qualified name matches qname.
GET-ITERATION( ) method (data objects)

Returns the buffer handle at a given level of iteration during a recursive FILL of a ProDataSet.

**Return type:** HANDLE

**Applies to:** Buffer object handle

**Syntax**

```plaintext
GET-ITERATION (level)
```

`level`

An integer expression indicating the level of iteration.

As a recursive ProDataSet FILL is proceeding, it creates clones of the relevant buffers, relations, queries and data-sources for each level of recursion. As a new record is added to the ProDataSet, it fires FILL events on the recursed, cloned buffer. From inside the event handler, you may want to see previous iterations of the buffer; its parent, grandparent, great-grandparent, and so on. GET-ITERATION( ) returns the buffer handle at a specified recursion level.

If the buffer object handle does not point to a ProDataSet temp-table or is not part of a recursive data-relation, GET-ITERATION returns the Unknown value (?).

**See also:** CURRENT-ITERATION attribute (data objects), FILL( ) method, NUM-ITERATIONS attribute (data objects), RECURSIVE attribute

GET-ITERATION( ) method (widget objects)

Returns the handle for the field group that represents the n-th visible iteration of the frame.

**Return type:** HANDLE

**Applies to:** FRAME widget

**Syntax**

```plaintext
GET-ITERATION (n)
```

`n`

An integer expression that specifies the number of a visible frame iteration.

You can read the NUM-ITERATIONS attribute of the frame to determine how many visible foreground (data) iterations the frame contains. You can then use the FIRST-CHILD or LAST-CHILD attributes of the field group to access the first or last field-level widget (respectively) in the iteration.

GET-LAST( ) method

Moves a query object’s result list pointer to the last row.
GET-LOCALNAME-BY-INDEX( ) method

Gets the local (unqualified) name of the attribute at the given 1-based index.

Return type: CHARACTER
Applies to: SAX-attributes object handle

Syntax

```
GET-LOCALNAME-BY-INDEX( index )
```

`index`

An integer expression indicating the 1-based index of the attribute.

Looks up an attribute’s local (unqualified) name by index. Returns the Unknown value (?) if namespace processing is disabled, if the index is less than 1, or if the index is greater than the value of the SAX-attributes object’s NUM-ITEMS attribute.
GET-MESSAGE( ) method (Handle)

Returns the message associated with a specified error currently recorded by the specified system handle.

**Return type:** CHARACTER

**Applies to:** COMPILER system handle, ERROR-STATUS system handle

**Syntax**

```
GET-MESSAGE ( n )
```

n

An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of the error whose information you want to retrieve.

For the COMPILER system handle, this is the message returned for the nth error that occurred during the preceding ABL source code compilation.

For the ERROR-STATUS system handle, this is the message returned for the nth error that occurred during the execution of a statement run with the NO-ERROR option.

GET-MESSAGE-TYPE( ) method

Returns the message type associated with the nth message that occurred during the preceding compilation.

**Return type:** INTEGER

**Applies to:** COMPILER system handle

**Syntax**

```
GET-MESSAGE-TYPE ( n )
```

n

An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of a compilation message. If the nth occurrence of a compilation message did not occur, the compiler issues a warning message at runtime.

The GET-MESSAGE-TYPE method returns one of the following values:

- **1** — Error message
- **2** — Warning message
- **3** — Preprocessor directive
GET-NEXT( ) method

Moves a query object’s result list pointer ahead one row.

**Return type:** LOGICAL

**Applies to:** Query object handle

**Syntax**

```
GET-NEXT ( NO-LOCK | SHARE-LOCK [, NO-WAIT ]
| EXCLUSIVE-LOCK [, NO-WAIT ]
)
```

**NO-LOCK**

Specifies that no lock is applied to the record. This applies to all buffers in a join. Unless explicitly specified otherwise, this is the default lock type for this method.

**SHARE-LOCK**

Specifies that the record is share locked. This applies to all buffers in a join.

**EXCLUSIVE-LOCK**

Specifies that the record is exclusively locked. This applies to all buffers in a join.

**NO-WAIT**

Specifies that the method returns immediately if the record cannot be accessed because it is locked by another user. If you do not use the NO-WAIT option, the method waits until the record can be accessed. This applies to all buffers in a join. If you specify NO-WAIT and the record is locked by another user, the record is returned to you with NO-LOCK and the LOCKED function returns TRUE for the record.

GET-NEXT() returns TRUE if the next record in the query is found. If the query is not open or the next record cannot be found (query is empty or the query result list pointer is on the last row), the method returns FALSE. If the query object handle is invalid, the method returns the Unknown value (?)

GET-NODE( ) method

Returns a handle to an X-noderef object that refers to the XML underlying a SOAP-header-entryref object or SOAP fault entry.

**Note:** A SOAP-header object contains a list of entries that each point to an exiting SOAP-header-entryref object. It is a SOAP-header-entryref object that the method is operating on.
GET-NUMBER( ) method

**Return type:** LOGICAL  
**Applies to:** SOAP-fault-detail object handle, SOAP-header-entryref object handle

**Syntax**

```
GET-NODE ( x-noderef )
```

`x-noderef`  
A variable of type X-noderef that refers to the root node of a DOM tree that has a SOAP header entry or SOAP fault entry as its root.

The X-noderef will have namespace declarations for all namespaces that are in effect for the SOAP header entry element. The X-noderef will include attributes for all attributes that the SOAP header entry has, including SOAP ENV:mustUnderstand and SOAP-ENV:Actor. Operations performed on the X NODEREF, its child X-noderefs, will directly affect the underlying header entry (note that this contrasts with the LONGCHAR returned from GET-SERIALIZED( ) method).

Returns the Unknown value (?) if the SOAP-header-entryref object handle has been initialized but does not refer to a header entry (for example, immediately after the CREATE SOAP-HEADER-ENTRYREF statement).

GET-NUMBER( ) method

Returns the error number associated with a specified error currently recorded by the specified system handle.

**Return type:** INTEGER  
**Applies to:** COMPILER system handle, ERROR-STATUS system handle

**Syntax**

```
GET-NUMBER ( n )
```

`n`  
An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of the error whose information you want to retrieve.

For the COMPILER system handle, this is the error number returned for the nth error that occurred during the preceding ABL source code compilation.

For the ERROR-STATUS system handle, this is the error number returned for the nth error that occurred during the execution of a statement run with the NO-ERROR option.

GET-PARENT( ) method

Retrieve the parent node of the node. The first parameter must be a valid X-noderef handle and will refer to the parent XML node if the node has a parent. If the node is the top “root” element in the document, this will return the Unknown value (?).
GET-PREV( ) method

Return type:  LOGICAL
Applies to:  X-noderef object handle

Syntax

```
GET-PARENT( x-node-handle )
```

**x-node-handle**

A valid X-noderef handle to use for the parent XML node.

The following example returns a handle to the parent XML node in hNoderefParent unless the hNoderef is the top “root” element in the hDoc. In that case, it returns the Unknown value (?).

```
hNoderef:GET-PARENT(hNoderefParent)
```

---

GET-PREV( ) method

Moves a query object’s result list pointer back one row.

Return type:  LOGICAL
Applies to:  Query object handle

Syntax

```
GET-NEXT ( NO-LOCK | SHARE-LOCK [ , NO-WAIT ] | EXCLUSIVE-LOCK [ , NO-WAIT ] )
```

**NO-LOCK**

Specifies that no lock is applied to the record. This applies to all buffers in a join. Unless explicitly specified otherwise, this is the default lock type for this method.

**SHARE-LOCK**

Specifies that the record is share locked. This applies to all buffers in a join.

**EXCLUSIVE-LOCK**

Specifies that the record is exclusively locked. This applies to all buffers in a join.

**NO-WAIT**

Specifies that the method returns immediately if the record cannot be accessed because it is locked by another user. If you do not use the NO-WAIT option, the method waits until the record can be accessed. This applies to all buffers in a join. If you specify NO-WAIT and the record is locked by another user, the record is returned to you with NO-LOCK and the LOCKED function returns TRUE for the record.
GET-PROPERTY( ) method

GET-PREV() returns TRUE if the previous record in the query is found. If the query is not open or the previous record cannot be found (query is empty or the query result list pointer is on the first row), the method returns FALSE. If the query object handle is invalid, the method returns the Unknown value (?).

A query that includes a BREAK BY phrase becomes a FORWARD-ONLY query. In this case you cannot use the GET-PREV() method. If you do, the AVM raises ERROR.

GET-PROPERTY( ) method

Gets the value of the specified application-defined property associated with the Client-principal object. The Client-principal object may be sealed or unsealed. If the specified property is not a valid property for the Client-principal object, or the property does not have a value, this method returns the Unknown value (?).

Return type: CHARACTER

Applies to: Client-principal object handle

Syntax

<table>
<thead>
<tr>
<th>GET-PROPERTY( property-name )</th>
</tr>
</thead>
</table>

property-name

A character string that specifies the name of an application-defined property associated with the Client-principal object. You must enclose this character string in quotes.

You can also use the LIST-PROPERTY-NAMES( ) method to retrieve a list of all application-defined properties associated with the Client-principal object.

The following code fragment illustrates how to use the GET-PROPERTY( ) method:

```assembly
define variable hCP as handle no-undo.
define variable vVal as character no-undo.
create client-principal hcp.
...vVal = hCP:GET-PROPERTY("eye-color").
display "Eye color: " vVal.
```

See also: LIST-PROPERTY-NAMES( ) method, SET-PROPERTY( ) method

GET-PRINTERS( ) method

(Windows only)

Returns a comma-separated list of printers defined in the Windows Registry.
GET-QNAME-BY-INDEX( ) method

Gets the XML qualified name of the attribute at the given 1-based index.

Return type: CHARACTER
Applies to: SAX-attributes object handle

Syntax

```
GET-QNAME-BY-INDEX( index )
```

index

An integer expression indicating the 1-based index of the attribute.

Looks up an attribute’s XML qualified name by index. Returns Unknown value (?) if the index is less than 1 or greater than the value of the SAX-attributes object’s NUM-ITEMS attribute.

---

GET-RED-VALUE( ) method

(Graphical interfaces only)

Returns the red component of an entry in the color table.

Return type: INTEGER
Applies to: COLOR-TABLE system handle

Syntax

```
GET-RED-VALUE( index )
```

index

An integer expression that specifies an entry in the color table.

---

GET-RELATION( ) method

Gets the handle of the specified data-relation object.
GET-REPOSITIONED-ROW( ) method

Return type: HANDLE
Applies to: ProDataSet object handle

Syntax

```
GET-RELATION ( index | relation-name )
```

*index*

An integer expression indicating the 1-based index of the data-relation object.

*relation-name*

A character expression that evaluates to the name of the data-relation object.

GET-REPOSITIONED-ROW( ) method

Returns the row index of the browse viewport where the REPOSITION TO ROWID (or RECID) statement displays a repositioned record.

Return type: INTEGER
Applies to: BROWSE widget

Syntax

```
GET-REPOSITIONED-ROW ( )
```

By default, this is the top row in the browse viewport (index 1). Note that this method is only useful in conjunction with the REPOSITION statement.

See the GET-REPOSITIONED-ROW( ) method reference entry for more information.

GET-RGB-VALUE( ) method

(Graphical interfaces only)

Returns an INTEGER that represents a combination of the red, green, and blue value of an entry in the color table.

Return type: INTEGER
Applies to: COLOR-TABLE system handle

Syntax

```
GET-RGB-VALUE ( index )
```

*index*

An integer expression that specifies an entry in the color table.

Note: This method is useful primarily when using colors with ActiveX controls.
GET-ROW( ) method

Returns the line number at which the $n$th message occurred during the preceding compilation.

**Return type:** INTEGER  
**Applies to:** COMPILER system handle

**Syntax**

```plaintext
GET-ROW ( n )
```

$n$

An integer expression, from 1 to the value of the NUM-MESSAGES attribute, that specifies the numeric occurrence of a compilation message. If the $n$th occurrence of a compilation message did not occur, the compiler issues a warning message at runtime.

---

GET-SELECTED-WIDGET( ) method

Returns the handle of the selected widget in a dialog box, frame, or window.

**Return type:** HANDLE  
**Applies to:** DIALOG-BOX widget, FRAME widget, WINDOW widget

**Syntax**

```plaintext
GET-SELECTED-WIDGET ( n )
```

$n$

An integer expression that specifies an index to a selected widget in a frame, dialog box, or window.

You can use the NUM-SELECTED-WIDGETS attribute to determine the total number of selected widgets within the frame or window. The order of the selected widgets is unpredictable.

---

GET-serialized( ) method

Returns a LONGCHAR that contains the serialized form of the XML underlying the SOAP-header-entryref or SOAP fault entry. (The SOAP-header object contains a list of entries that each point to an exiting SOAP-header-entryref object. It is the SOAP-header-entryref object that the method serializes.)

**Return type:** LONGCHAR  
**Applies to:** SOAP-fault-detail object handle, SOAP-header-entryref object handle

**Syntax**

```plaintext
GET-serialized ( )
```
Contents of the returned LONGCHAR are equivalent to taking the X-noderef returned by the GET-NODE( ) method and serializing the data. The caller of this method is responsible for managing the lifetime of the LONGCHAR. Changes made to the contents of the LONGCHAR will NOT be reflected in the original header entry unless it is passed as the parameter in the SET-serialized( ) method.

Returns the Unknown value (?) if the SOAP-header-entryref object handle has been initialized but does not refer to a header entry (for example, immediately after the CREATE SOAP-HEADER-ENTRYREF statement).

**GET-SIGNATURE( ) method**

Returns the signature of the internal procedure or user-defined function whose name you supply. Specifically:

- If you provide the name of an internal procedure, GET-SIGNATURE returns the type and mode of each parameter.
- If you provide the name of a user-defined function, GET-SIGNATURE returns the return type, and the type and mode of each parameter.
- If you provide the nil procedure name (""), GET-SIGNATURE returns the signature of the procedure whose handle you supply.
- If you provide a name that does not match any of the internal procedures or user-defined functions in the procedure, GET-SIGNATURE returns the empty string ("").
- If you provide a remote (proxy) procedure handle or the name of a Web service procedure, GET-SIGNATURE returns the empty string ("").
- If you provide the name of a DLL entry point, GET-SIGNATURE returns the ABL equivalent of the C data type of each parameter of the entry point. For more information, see *OpenEdge Development: Programming Interfaces*.

**Note:** GET-SIGNATURE does not return the signature of any internal procedure defined using the PROCEDURE statement’s PRIVATE option. Similarly, GET-SIGNATURE does not return the signature of any user-defined function defined using the FUNCTION statement’s PRIVATE option.

**Return type:** CHARACTER  
**Applies to:** Procedure object handle  
**Syntax**

```
GET-SIGNATURE ( int-proc-name )
```

*int-proc-name*

The name of an internal procedure or user-defined function.

GET-SIGNATURE returns a string with the following format:
GET-SIGNATURE( ) method

\[
\text{type, return-type, \[ mode \ name \ p-type \ [ , mode \ name \ p-type \] \ldots ]}
\]

\textbf{type}

The type of the internal procedure. Types include:

- **PROCEDURE** — An ABL internal procedure
- **FUNCTION** — An ABL user-defined function whose definition resides in the procedure
- **EXTERN** — An ABL user-defined function whose definition resides in another procedure
- **DLL-ENTRY** — A DLL entry point
- **MAIN** — The main procedure

\textit{return-type}

(User-defined functions only) The ABL data type that a user-defined function returns.

\textit{mode name p-type}

A parameter description where \textit{mode} is the mode of the parameter, \textit{name} is the name of the parameter, and \textit{p-type} is the type of parameter. The parameter type is either a data type (scalar or array) or, for a buffer parameter, the name of the table associated with the buffer.

The modes are:

- INPUT
- OUTPUT
- INPUT-OUTPUT
- BUFFER
- INPUT TABLE
- OUTPUT TABLE
- INPUT-OUTPUT TABLE

The data types are:

- CHARACTER
- DATE
- DATETIME
- DATETIME-TZ
- DECIMAL
- HANDLE
GET-SOCKET-OPTION( ) method

When you define the parameter type as a determinate array with a constant extent value, the GET-SIGNATURE( ) method returns the constant extent value specified as part of the signature (for example, EXTENT 100). When you define the parameter type as a determinate array with a variable extent value, or as an indeterminate array, the GET-SIGNATURE( ) method returns only the extent keyword (that is, EXTENT, with no extent value).

GET-SOCKET-OPTION( ) method

Returns a comma separated string containing values appropriate for the specified socket option. Otherwise, it returns the Unknown value (?)..

**Return type:** CHARACTER  
**Applies to:** Socket object handle

**Syntax**

```
GET-SOCKET-OPTION( name )
```

`name`

A character expression indicating the name of the socket option to be retrieved. Table 82 describes the options ABL supports.

**Table 82: Options for GET-SOCKET-OPTION( )** (1 of 2)

<table>
<thead>
<tr>
<th>Option</th>
<th>Value returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP-NODELAY</td>
<td>An enable indicator, which is either TRUE or FALSE.</td>
</tr>
<tr>
<td>SO-LINGER</td>
<td>Two comma separated values:</td>
</tr>
<tr>
<td></td>
<td>- The onoff indicator, which is either TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>- The linger time. If the onoff indicator is FALSE, the linger time does not need to be provided.</td>
</tr>
</tbody>
</table>
This method returns option-specific data if the retrieval of the option succeeded and the Unknown value (?) otherwise. An error can occur if:

- The value of name is not an ABL-supported socket option
- Getting the socket option fails

### Table 82: Options for GET-SOCKET-OPTION( )

<table>
<thead>
<tr>
<th>Option</th>
<th>Value returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO-KEEPALIVE</td>
<td>TRUE if the option is on; FALSE otherwise.</td>
</tr>
<tr>
<td></td>
<td>The default depends on how the socket object was created:</td>
</tr>
<tr>
<td></td>
<td>• For socket objects created using CREATE SOCKET, the default is off.</td>
</tr>
<tr>
<td></td>
<td>• For socket objects created by ABL and passed as a parameter to the event-procedure context, the default is on.</td>
</tr>
<tr>
<td>SO-REUSEADDR</td>
<td>TRUE if the option is on; FALSE otherwise.</td>
</tr>
<tr>
<td></td>
<td>The default depends on the platform.</td>
</tr>
<tr>
<td>SO-RCVBUF</td>
<td>An integer that indicates the size of the receive buffer.</td>
</tr>
<tr>
<td></td>
<td>The default depends on the platform.</td>
</tr>
<tr>
<td>SO-SNDBUF</td>
<td>An integer that indicates the size of the send buffer.</td>
</tr>
<tr>
<td></td>
<td>The default depends on the platform.</td>
</tr>
<tr>
<td>SO-RCVTIMEO</td>
<td>The timeout length—that is, the number of seconds you want the socket to wait for expected data before timing out.</td>
</tr>
<tr>
<td></td>
<td>The default is -1, which tells the socket to wait forever.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The timeout length is not guaranteed to be precise to the second.</td>
</tr>
</tbody>
</table>

### GET-SOURCE-BUFFER( ) method

Gets the handle to the source buffer in the Data-source object at the specified index position.

- **Return type:** HANDLE
- **Applies to:** Data-source object handle

#### Syntax

```
GET-SOURCE-BUFFER ( [ buffer-index ] )
```

**buffer-index**

An optional integer expression indicating the 1-based index of the source buffer. The default is 1.
GET-TAB-ITEM( ) method

Returns the handle of a widget at a specified tab position in a field group.

**Return type:** HANDLE  
**Applies to:** FIELD-GROUP widget

**Syntax**

```
GET-TAB-ITEM( n )
```

*n*

An integer expression that specifies a tab position within a field group.

You can use the MOVE-AFTER-TAB-ITEM( ) and MOVE-BEFORE-TAB-ITEM( ) methods to change the tab position of fields at the field level, and the FIRST-TAB-ITEM and LAST-TAB-ITEM attributes to change the tab positions at the field group level.

If the widget returned is a frame, the specified tab position includes the tab positions of all tab-order widgets contained by the frame. For more information on how frames owned by a field group participate in the tab order of that field group, see the FRAME widget reference entry.

---

GET-TEXT-HEIGHT-CHARS( ) method  
(Graphical interfaces only)

Returns the height, in character units, of the specified font. If no font is specified, the method returns the height of the default font.

**Return type:** DECIMAL  
**Applies to:** FONT-TABLE system handle

**Syntax**

```
GET-TEXT-HEIGHT-CHARS( [ font ] )
```

*font*

An integer expression that specifies an entry within the font.

If you pass the Unknown value (?) to this method, the AVM uses the system default font. When a field-level widget inherits its font from the parent frame, the AVM returns the Unknown value (?) for the font and you must use the font of the parent frame.

---

GET-TEXT-HEIGHT-PIXELS( ) method  
(Graphical interfaces only)

Returns the height, in pixels, of the specified font. If no font is specified, the method returns the height of the default font.
GET-TEXT-WIDTH-CHARS( ) method

Return type: INTEGER
Applies to: FONT-TABLE system handle

Syntax

GET-TEXT-HEIGHT-PIXELS ( [ font ] )

font

An integer expression that specifies an entry within the font table.

If you pass the Unknown value (?) to this method, the AVM uses the system default font. When a field-level widget inherits its font from the parent frame, the AVM returns the Unknown value (?) for the font and you must use the font of the parent frame.

GET-TEXT-WIDTH-CHARS( ) method
(Graphical interfaces only)

Returns the width, in character units, of the string using the specified font. If no font is specified, the method calculates the width of the string using the default font.

Return type: DECIMAL
Applies to: FONT-TABLE system handle

Syntax

GET-TEXT-WIDTH-CHARS ( string [ , font ] )

string

A character-string expression whose width you want to determine.

font

An integer expression that specifies an entry within the font table.

If you pass the Unknown value (?) to this method, the AVM uses the system default font. When a field-level widget inherits its font from the parent frame, the AVM returns the Unknown value (?) for the font and you must use the font of the parent frame.

GET-TEXT-WIDTH-PIXELS( ) method
(Graphical interfaces only)

Returns the width, in pixels, of the string using the specified font. If no font is specified, the method calculates the width of the string using the default font.
GET-TOP-BUFFER( ) method

**Return type:** INTEGER  
**Applies to:** FONT-TABLE system handle

**Syntax**

```
GET-TEXT-WIDTH-PIXELS ( string [, font ] )
```

- **string**
  
  A character-string expression whose width you want to determine.

- **font**
  
  An integer expression that specifies an entry within the font table.

If you pass the Unknown value (?) to this method, the AVM uses the system default font. When a field-level widget inherits its font from the parent frame, the AVM returns the Unknown value (?) for the font and you must use the font of the parent frame.

GET-TOP-BUFFER( ) method

Gets the top-level buffer in a ProDataSet object at the specified index position.

**Note:** A top-level buffer is a ProDataSet object buffer that is not a child in any active data relation. There may be one or more top-level buffers in a ProDataSet object.

**Return type:** HANDLE  
**Applies to:** ProDataSet object handle

**Syntax**

```
GET-TOP-BUFFER ( index )
```

- **index**
  
  An integer expression indicating the 1-based index of the top-level buffer.

GET-TYPE-BY-INDEX( ) method

Gets the type of the attribute at the given 1-based index.

**Return type:** CHARACTER  
**Applies to:** SAX-attributes object handle

**Syntax**

```
GET-TYPE-BY-INDEX ( index )
```

- **index**
  
  An integer expression indicating the 1-based index of the attribute.
GET-TYPE-BY-NAMESPACE-NAME( ) method

The attribute type is one of the following strings: “CDATA,” “ID,” “IDREF,” “IDREFS,” “NMTOKEN,” “NMTOKENS,” “ENTITY,” “ENTITIES,” or “NOTATION.” These are always uppercase.

Returns the Unknown value (?) if the index is less than 1 or greater than the value of SAX-attributes object’s NUM-ITEMS attribute.

GET-TYPE-BY-QNAME( ) method

Gets the type of the attribute with the given XML qualified name.

Return type: CHARACTER
Applies to: SAX-attributes object handle

Syntax

```
GET-TYPE-BY-QNAME ( qname )
```

qname

A CHARACTER expression indicating the XML qualified name of the attribute of interest.
The attribute type is one of the following strings: “CDATA,” “ID,” “IDREF,” “IDREFS,” “NMTOKEN,” “NMTOKENS,” “ENTITY,” “ENTITIES,” or “NOTATION.” These are always uppercase.

Returns the Unknown value (?) if no attribute’s XML qualified name matches $qname$. 

---

**GET-URI-BY-INDEX( ) method**

Gets the namespace URI of the attribute at the given 1-based index.

<table>
<thead>
<tr>
<th>Return type:</th>
<th>CHARACTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to:</td>
<td>SAX-attributes object handle</td>
</tr>
</tbody>
</table>

**Syntax**

```
GET-URI-BY-INDEX ( index )
```

`index`

An integer expression indicating the 1-based index of the attribute.

Returns the Unknown value (?) if `index` is less than 1 or greater than the value of the SAX-attributes object's NUM-ITEMS attribute.

---

**GET-VALUE-BY-INDEX( ) method**

Gets the value of the attribute at the given 1-based index.

<table>
<thead>
<tr>
<th>Return type:</th>
<th>CHARACTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to:</td>
<td>SAX-attributes object handle</td>
</tr>
</tbody>
</table>

**Syntax**

```
GET-VALUE-BY-INDEX ( index )
```

`index`

An integer expression indicating the 1-based index of the attribute.

Returns the Unknown value (?) if `index` is less than 1 or greater than the value of the SAX-attributes object's NUM-ITEMS attribute.

---

**GET-VALUE-BY-NAMESPACE-NAME( ) method**

Gets the value of the attribute with the given namespace name.
GET-VALUE-BY-QNAME( ) method

Gets the value of the attribute with the given XML qualified name.

Return type: CHARACTER
Applies to: SAX-attributes object handle

Syntax

```
GET-VALUE-BY-QNAME ( qname )
```

qname

A CHARACTER expression indicating the XML qualified name of the attribute.

Returns the Unknown value (?) if no attribute has a XML qualified name that matches qname.

GET-WAIT-STATE( ) method

Returns a string indicating the current wait-state.

Return type: CHARACTER
Applies to: SESSION system handle

Syntax

```
GET-WAIT-STATE ( )
```

If the SET-WAIT-STATE( ) method was called with “GENERAL” or “COMPILER”, GET-WAIT-STATE( ) returns that string. If the SET-WAIT-STATE( ) method was called with an arbitrary pointer name, GET-WAIT-STATE( ) returns “CUSTOM”. If there is no current wait-state, GET-WAIT-STATE( ) returns an empty string ("").
**GRAPHIC-EDGE attribute**

*(Character interfaces only)*

Indicates whether to draw a rectangle with graphic characters.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** RECTANGLE widget

When the GRAPHIC-EDGE attribute is TRUE, the rectangle is drawn with graphic characters, and the EDGE-CHARS and EDGE-PIXELS attributes are ignored.

**GRID-FACTOR-HORIZONTAL attribute**

*(Graphical interfaces only)*

The spacing, in horizontal grid units, between the horizontal grid lines of the frame.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** FRAME widget

If the value is 1, each horizontal grid unit is intersected by a line of vertical grid points. If the value is greater than 1, every $n$th horizontal grid unit is intersected by a line of vertical grid points, where $n$ is the value of GRID-FACTOR-HORIZONTAL. The default value is 6.

The width of a horizontal grid unit is defined by the GRID-UNIT-WIDTH-CHARS or GRID-UNIT-WIDTH-PIXELS attribute.

**Note:** Setting this attribute to 1 has the same effect as setting the GRID-FACTOR-VERTICAL attribute to 1, because either setting makes all grid points visible in the frame.

**GRID-FACTOR-VERTICAL attribute**

*(Graphical interfaces only)*

The spacing, in vertical grid units, between the vertical grid lines of the frame.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** FRAME widget

If the value is 1, each vertical grid unit is intersected by a line of horizontal grid points. If the value is greater than 1, every $n$th vertical grid unit is intersected by a horizontal line of grid points, where $n$ is the value of GRID-FACTOR-VERTICAL. The default value is 6.

The height of a vertical grid unit is defined by the GRID-UNIT-HEIGHT-CHARS or GRID-UNIT-HEIGHT-PIXELS attribute.
**Note:** Setting this attribute to 1 has the same effect as setting the GRID-FACTOR-HORIZONTAL attribute to 1, because either setting makes all grid points visible in the frame.

---

**GRID-SNAP attribute**  
(Graphical interfaces only)

Indicates whether widgets should snap to the grid when they are moved or resized.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** FRAME widget

If the GRID-SNAP attribute is TRUE, when widgets are moved or resized they align with (snap to) the closest grid points in the frame. This alignment occurs whether or not the grid points are visible (determined by the GRID-VISIBLE attribute).

The distance between grid points (vertical and horizontal grid units) is defined by the GRID-UNIT-HEIGHT-CHARS, GRID-UNIT-HEIGHT-PIXELS, GRID-UNIT-WIDTH-CHARS, and GRID-UNIT-WIDTH-PIXELS attributes.

---

**GRID-UNIT-HEIGHT-CHARS attribute**  
(Graphical interfaces only)

The height, in character units, of a vertical grid unit on the frame.

**Data type:** DECIMAL  
**Access:** Readable/Writeable  
**Applies to:** FRAME widget

This attribute specifies the distance between vertical grid points in the frame. When a widget is moved or resized, it snaps to these grid points within the frame when the GRID-SNAP attribute is set to TRUE. The default value depends on the display resolution and the size of the default system font.

---

**GRID-UNIT-HEIGHT-PIXELS attribute**  
(Graphical interfaces only)

The height, in pixels, of a vertical grid unit on the frame.
GRID-UNIT-WIDTH-CHARS attribute

Data type: INTEGER
Access: Readable/Writeable
Applies to: FRAME widget

This attribute specifies the distance between vertical grid points in the frame. When a widget is moved or resized, it snaps to these grid points within the frame when the GRID-SNAP attribute is set to TRUE. The default value is 6.

GRID-UNIT-WIDTH-CHARS attribute (Graphical interfaces only)

The width, in character units, of a horizontal grid unit on the frame.

Data type: DECIMAL
Access: Readable/Writeable
Applies to: FRAME widget

This attribute specifies the distance between horizontal grid points in the frame. When a widget is moved or resized, it snaps to these grid points within the frame when the GRID-SNAP attribute is set to TRUE. The default value depends on the display resolution and the size of the default system font.

GRID-UNIT-WIDTH-PIXELS attribute (Graphical interfaces only)

The width, in pixels, of a horizontal grid unit on the frame.

Data type: INTEGER
Access: Readable/Writeable
Applies to: FRAME widget

This attribute specifies the distance between horizontal grid points in the frame. When a widget is moved or resized, it snaps to these grid points within the frame when the GRID-SNAP attribute is set to TRUE. The default value is 6.

GRID-VISIBLE attribute (Graphical interfaces only)

Indicates whether the grid of a frame is visible.
GROUP-BOX attribute

When visible, the grid is a set of points laid out in vertical and horizontal lines. The distance between grid points (vertical and horizontal grid units), whether visible or invisible, is defined by using the GRID-UNIT-HEIGHT-CHARS, GRID-UNIT-HEIGHT-PIXELS, GRID-UNIT-WIDTH-CHARS, and GRID-UNIT-WIDTH-PIXELS attributes. What grid points are visible is determined by the GRID-FACTOR-VERTICAL and GRID-FACTOR-HORIZONTAL attributes, which define the spacing between the visible vertical and horizontal lines of grid points.

When used with scrollable frames, some grid points might not be visible.

GROUP-BOX attribute
(Graphical interfaces only)

Indicates the rectangle is a group box, which surrounds one or more user interface widgets to visually indicate a relationship among the widgets.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: RECTANGLE widget

The appearance of a group box changes automatically to conform to the current display setting. When the display is set to the Windows XP Theme, the group box rectangle appears with rounded corners and a single-line border. When the display is set to the Windows Classic Theme, the group box appears with square corners and a shaded double-line border.

If you set this attribute after the widget is realized, its affect is immediate (if the widget is visible).

When TRUE, the ROUNDED attribute setting is ignored.

See also: ROUNDED attribute

HANDLE attribute

A handle to the object.

Data type: HANDLE
Access: Readable
Applies to: Asynchronous request object handle, AUDIT-CONTROL system handle, AUDIT-POLICY system handle, BROWSE widget (browse, column, and cell), Buffer object handle, Buffer-field object handle, BUTTON widget, Call object handle, Client-principal object handle, CLIPBOARD system handle, CODEBASE-LOCATOR system handle, COLOR-TABLE system handle, COMBO-BOX widget, COMPILER system handle, Data-relation object handle, Data-source object handle, DEBUGGER system handle,
You can store this value in a HANDLE variable. You can also use it to associate one widget with another widget or with a system handle. For example, you can assign the HANDLE value of the menu bar to the MENU-BAR attribute of a window, or you can make the window the current window by assigning its HANDLE value to the CURRENT-WINDOW handle.

For query objects, the HANDLE attribute lets you acquire a query object for a static query, as the following fragment demonstrates:

```
my-query-handle = QUERY q:HANDLE.
```

The following code fragment uses the HANDLE attribute of a buffer-field to retrieve the buffer-field’s handle:

```
my-buffer-field = city:HANDLE IN BUFFER Customer.
```

The preceding code fragment requires that you know the name of the field (in this case, “City”) at compile time. The following code fragment, which performs the same task, does not require this:

```
my-buffer = BUFFER Customer:HANDLE
my-buffer-field = my-buffer:BUFFER-FIELD("City").
```

The value of a the HANDLE attribute is guaranteed to be unique among the HANDLE attributes for all object instances in an ABL session.

**HANDLER attribute**

A handle to the procedure containing the SAX callbacks.
HAS-LOBS attribute

Data type: HANDLE
Access: Readable/Writable
Applies to: SAX-reader object handle

The default is a handle to the procedure that contains the SAX-PARSE() method, or the SAX-PARSE-FIRST( ) and SAX-PARSE-NEXT( ) methods.

When SAX-PARSE(), SAX-PARSE-FIRST(), or SAX-PARSE-NEXT() executes, the SAX-reader object looks for callbacks only in the procedure whose handle is stored in HANDLER. HANDLER must be a valid procedure handle and cannot be a proxy.

Note: It is permissible for both the driver procedure (the procedure that contains the SAX-PARSE() method, or the SAX-PARSE-FIRST( ) and SAX-PARSE-NEXT( ) methods) and handler procedure of a SAX application to reside on a remote AppServer. If this occurs, callbacks are invoked local to the AppServer.

Callbacks can reside within a special handler procedure file that is run persistently or within the driver procedure.

Within a procedure file, to get a handle to the procedure file, use the THIS-PROCEDURE handle. The following fragment assigns HANDLER a handle to the current procedure:

```has
hSaxReader:HANDLER = THIS-PROCEDURE.
```

HAS-LOBS attribute

Returns TRUE if the Buffer object has BLOB or CLOB fields defined in it. Otherwise, it returns FALSE.

Data type: LOGICAL
Access: Readable
Applies to: Buffer object handle

HAS-RECORDS attribute

This attribute returns TRUE when the corresponding temp-table has records. It returns FALSE when the temp-table does not have any records, or the temp-table is in an UNPREPARED state.
Height property

(Windows only; Graphical interfaces only)

The height of the control-frame and control-frame COM object, in pixels.

Return type: INTEGER
Access: Readable/Writeable
Applies to: CONTROL-FRAME widget, COM object

Setting this value changes the HEIGHT-CHARS attribute and HEIGHT-PIXELS attribute of the corresponding control-frame widget to an equivalent value.

Note: References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

HEIGHT-CHARS attribute

The height, in character units, of the widget. The HEIGHT-CHARS attribute of the SESSION handle contains the height of the display.

Data type: DECIMAL
Access: Readable/Writeable
Applies to: BROWSE widget (browse and cell), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SESSION system handle, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

For combo boxes, field groups, and the SESSION handle, this attribute is read-only.

In character mode, the HEIGHT-CHARS attribute must be set before the browse is realized. Attempting to set the attribute after realization of the browse causes a run-time error.

For control-frames, the HEIGHT-CHARS attribute maps to the Height property of the control-frame COM object (ActiveX control container).

For browses, the HEIGHT-CHARS attribute sets the decimal height, in characters, of the browse without changing the height of the browse’s rows. If you change the value of a browse’s HEIGHT-CHARS or HEIGHT-PIXELS attribute, the number of rows that appear in the viewport might change.
**HEIGHT-PIXELS attribute**

The height, in pixels, of the widget. The HEIGHT-PIXEL attribute of the SESSION handle contains the height of the display.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (browse and cell), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SESSION system handle, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

For combo boxes, field groups, and the SESSION handle, this attribute is read-only.

In character mode, the HEIGHT-PIXELS attribute must be set before the browse is realized. Attempting to set the attribute after realization of the browse causes a run-time error.

For control-frames, the HEIGHT-PIXELS attribute maps to the Height property of the control-frame COM object (ActiveX control container).

For browses, the HEIGHT-PIXELS attribute sets the decimal height, in pixels, of the browse without changing the height of the browse’s rows. If you change the value of a browse’s HEIGHT-CHARS or HEIGHT-PIXELS attribute, the number of rows that appear in the viewport might change.

---

**HELP attribute**

The help text for a field.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (browse and column), Buffer-field object handle, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

For this attribute to have effect, the window that contains the specified widget must have its STATUS-AREA attribute set to TRUE. The text stored in the HELP attribute displays in the status area of the containing window when the widget has input focus. The HELP attribute text overrides any status-area text issued by the STATUS statement.

---

**HIDDEN attribute**

Indicates whether to “hide” a widget.
Setting the HIDDEN attribute to TRUE prevents the widget from being displayed implicitly. For a field-level widget, child frame, or child window, this means that the widget is not automatically made visible when the containing frame or parent window becomes visible. The widget does not appear unless one of the following occurs:

- It is forced to receive user input (for example, using a SET or PAUSE statement).
- It is explicitly displayed using a VIEW statement or by setting its VISIBLE attribute to TRUE.

Any action that explicitly displays the widget also resets the HIDDEN attribute to FALSE. If the widget is already visible, setting its HIDDEN attribute to TRUE makes that widget and any widgets its parents (and their descendants) invisible (VISIBLE is set to FALSE). The default value of the HIDDEN attribute is FALSE for all widgets.

In windows, setting the HIDDEN attribute to TRUE prevents implicit display of the hidden window when you:

- Invoke DISPLAY, ENABLE, and VIEW statements for frames of the window
- View an ancestor or descendant window of the hidden window

This limits flashing side effects caused during set up of the application user interface. In windows, this attribute is not supported in character mode.

For frames and dialog boxes, setting the HIDDEN attribute to TRUE prevents implicit display of the frame or dialog box when you invoke DISPLAY or ENABLE statements for the widget or its descendant frames. This allows the frame or dialog box to remain invisible during actions that set it up. The HIDDEN attribute has no effect on DISPLAY statements directed to a file, pipe, or printer.

**Note:** Setting a frame or field-level widget’s VISIBLE attribute to TRUE also displays any parent or ancestor frames, even if their HIDDEN attributes are set to TRUE (resetting the HIDDEN attributes, if necessary). However, setting a window’s VISIBLE attribute to TRUE only displays the window if there are no ancestor windows with their HIDDEN attribute set to TRUE. In any case, the window’s own HIDDEN attribute is set to FALSE.

For field-level widgets and frames parented by other frames, setting the HIDDEN attribute to TRUE prevents implicit display of the field-level widget or child frame when its containing frame or dialog box is displayed. If the frame or dialog box containing the widget is visible, setting HIDDEN to FALSE for the widget makes the widget visible (the VISIBLE attribute is set to TRUE). If the containing frame or dialog box is not visible, setting HIDDEN to FALSE has no effect on the VISIBLE attribute of the widget.
HonorProKeys property
(Windows only; Graphical interfaces only)

Determines who processes the GO, ENDKEY, HELP, and TAB keys: the AVM, or the ActiveX control to which the property applies.

Data type: LOGICAL  
Access: Readable/Writeable  
Applies to: Any ActiveX control

If the property is TRUE, which is the default, the AVM intercepts these keys and processes them as normal ABL key events. If the property is FALSE, the keystrokes are sent to the ActiveX control for processing.

Note: This property resembles the HonorReturnKey property, which governs processing of the RETURN key, but whereas the default setting for HonorProKeys is TRUE (the AVM gets the event), the default setting for HonorReturnKey is FALSE (the ActiveX control gets the event).

HonorReturnKey property
(Windows only; Graphical interfaces only)

Determines who processes the RETURN key: the AVM, or the ActiveX control to which the property applies.

If the property is TRUE, the AVM intercepts the key and processes it as a normal ABL RETURN key event. If the property is FALSE, which is the default, the keystroke is sent to the ActiveX control for processing.

Data type: LOGICAL  
Access: Readable/Writeable  
Applies to: Any ActiveX control

If a frame has a default button and an ActiveX control, and you want the RETURN key to activate the default button regardless of who has focus, you must set the HonorReturnKey property of the ActiveX control to TRUE. Similarly, if a frame has a default button and several ActiveX controls, and you want the RETURN key to activate the default button regardless of who has focus, you must set the HonorReturnKey property of all the ActiveX controls in the frame to TRUE.

This property resembles the HonorProKeys property, which governs processing of several other keys, but whereas the default setting for HonorReturnKey is FALSE (the ActiveX control gets the event), the default setting for HonorProKeys is TRUE (the AVM gets the event).
HORIZONTAL attribute

The orientation of a slider, or of radio buttons in a radio set.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** RADIO-SET widget, SLIDER widget

If HORIZONTAL is TRUE, the orientation is horizontal; if it is FALSE, the orientation is VERTICAL. By default, the orientation of sliders is horizontal and the orientation of radio sets is vertical.

You can set this attribute only before the widget is realized.

---

HTML-CHARSET attribute  
(WebSpeed only)

The ABL version (as opposed to the MIME version) of the code page name of a Web request. Set by ABL when a WebSpeed application incorporates dynamic code page support. The default is blank.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** WEB-CONTEXT system handle

Once the AVM sets HTML-CHARSET, each time a Web browser sends a Web request to the application:

1. The request is received by the WebSpeed Agent. The AVM converts it from the HTML-CHARSET code page to the Agent’s CPINTERNAL code page.

2. The Agent responds to the request with a Web page. The AVM converts the Web page from the Agent’s CPINTERNAL code page to the HTML-CHARSET code page.

---

**Caution:** If the application modifies the contents of HTML-CHARSET, dynamic code-page support might fail.

For more information on dynamic code-page support, see *OpenEdge Application Server: Developing WebSpeed Applications*.

---

HTML-END-OF-LINE attribute

Defaults to the newline character (ASCII 10; `~n`; `\n`). A null string value causes a NEWLINE character (not a null string) to be output. You might want to set this to `~n` (the NEWLINE character) or to the null string (to force the NEWLINE character). Depending on the other attribute values, using the NEWLINE rather than the `<BR>` tag can result in more readable output when viewing document source in a browser.
**HTML-END-OF-PAGE attribute**

Between stream pages, defaults to "<HR>". Output between stream pages to visually break up the sectioning caused by the PAGED or PAGE-SIZE options of the OUTPUT TO "WEB" statement. Does not affect the line count of any stream page.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HTML-HEADER-BEGIN attribute**

Before the column headers of a SpeedScript frame, defaults to "<PRE>". Generally, if you change this value you must change the value of HTML-HEADER-END. Output at the beginning of the column header section of a DOWN frame.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HTML-FRAME-BEGIN attribute**

Before a SpeedScript frame, defaults to "<PRE>". Generally, if you change this value you must change the value of HTML-FRAME-END. Output only before the data row(s) for the current iteration of a DOWN frame, not to column headers (see also HTML-HEADER-BEGIN and HTML-HEADER-END). Applies to any side-labels displayed in the frame, whether or not the frame is a DOWN frame.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HTML-FRAME-END attribute**

After a SpeedScript frame, defaults to "</PRE>". Generally, if you change this value you must change the value of HTML-FRAME-BEGIN. Output at the end of the data row(s) for the current iteration of a DOWN frame.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HTML-HEADER-BEGIN attribute**

Before the column headers of a SpeedScript frame, defaults to "<PRE>". Generally, if you change this value you must change the value of HTML-HEADER-END. Output at the beginning of the column header section of a DOWN frame.
**HTML-HEADER-END attribute**

After the column headers of a SpeedScript frame, defaults to "</PRE>". Generally, if you change this value you must change the value of HTML-HEADER-BEGIN. Output at the end of the column header section of a DOWN frame.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HTML-TITLE-BEGIN attribute**

Before a SpeedScript frame title, Defaults to the null string (""), no text. Generally, if you change this value you must change the value of HTML-TITLE-END. Output before the frame’s TITLE value. Setting to a color or bold tag might improve readability.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HTML-TITLE-END attribute**

After a SpeedScript frame title, defaults to the null string (""), no text. Generally, if you change this value you must change the value of HTML-TITLE-BEGIN. Output after the frame’s TITLE value.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** WEB-CONTEXT system handle

**HWND attribute**

(Windows only; Graphical interfaces only)

An integer value for a Windows handle to the window that contains the widget.

- **Data type:** INTEGER
- **Access:** Readable
- **Applies to:** BROWSE widget (browse and cell), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR
ICFPARAMETER attribute

A character string that supplies Internet Component Framework (ICF) procedures (in Progress Dynamics®) with ICF-related data.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** SESSION system handle

Use the ICF Parameter (-icfparam) parameter to specify a character string, at the start of an ABL session, that can be accessed from ABL procedures within the ICF framework.

**Note:** The ICF Parameter (-icfparam) parameter is reserved for use by the ICF and procedures that have been integrated with the ICF. Using this parameter for any purpose other than operating within the ICF framework will interfere with your ability to integrate your application with that framework at a later time.

ICON attribute

Returns the name of the icon loaded by LOAD-ICON( ).

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** WINDOW widget

IGNORE-CURRENT-MODIFIED attribute

This attribute is supported only for backward compatibility. Use the PREFER-DATASET attribute instead.
IMAGE attribute

Returns the name of the image loaded by LOAD-IMAGE( ).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** BUTTON widget, IMAGE widget

IMAGE-DOWN attribute

Returns the name of the image loaded by LOAD-IMAGE-DOWN( ).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** BUTTON widget

IMAGE-INSENSITIVE attribute

Returns the name of the image loaded by LOAD-IMAGE-INSENSITIVE( ).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** BUTTON widget

IMAGE-UP attribute

Returns the name of the image loaded by LOAD-IMAGE( ) or LOAD-IMAGE-UP( ).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** BUTTON widget

IMMEDIATE-DISPLAY attribute  
(Graphical interfaces only)

The frequency of screen updates for the current session.
IMPORT-NODE( ) method

If TRUE, the AVM updates the display for every I/O operation, including DISPLAY statements. If FALSE, the AVM does not update the display until a statement blocks for input, such as an UPDATE statement. FALSE is the default setting. A TRUE setting provides more accurate screen displays during long display loops at the price of slower performance.

In Windows, this attribute has a similar effect on interactive I/O to setting the MULTITASKING-INTERVAL attribute to a low non-zero value, providing a more frequent display refresh. This attribute also provides the same functionality as the ImmediateDisplay parameter in the current environment (which might be the Registry (Windows only) or an initialization file). For more information on environments, see the chapter on user interface environments in *OpenEdge Deployment: Managing ABL Applications*.

**IMPORT-NODE( ) method**

Import a copy of a node from another document into this document. The first parameter must be a valid X-noderef handle and will refer to the newly copied XML node if the method succeeds. The new node is associated with this document, but must be appended or inserted with APPEND-CHILD( ) or INSERT-BEFORE( ) to become part of the structure.

**Return type:** LOGICAL

**Applies to:** X-document object handle

**Syntax**

```
IMPORT-NODE( x-node, x-source-node, deep )
```

**x-node**

A valid X-noderef handle to use for the new XML node.

**x-source-node**

A valid X-noderef handle that represents the node to import from.

**deep**

A logical that if TRUE specifies that the whole sub-tree is to be copied. The default value is FALSE.

If hDoc is an existing and loaded X-document and hDocCopy is existing but empty and hRoot and hRootCopy are X-noderefs, you can copy hDoc to hDocCopy as follows:

```c
/* Associates hRoot with the root node of the hDoc document. */
hDoc:GET-DOCUMENT-ELEMENT(hRoot).
hDocCopy:IMPORT-NODE(hRootCopy, hRoot, TRUE).
hDocCopy:APPEND-CHILD(hRootCopy).
```
IMPORT-PRINCIPAL( ) method

Imports a sealed Client-principal object, from its raw data form, and assigns it to a
Client-principal object handle. The receiving Client-principal object handle assumes the
property and attribute settings defined in the source object when it was exported using the
EXPORT-PRINCIPAL( ) method.

Return type: LOGICAL
Applies to: Client-principal object handle

Syntax

```
IMPORT-PRINCIPAL( expression )
```

expression

A RAW expression containing the Client-principal object data to import. If the specified
expression has the Unknown value (?), the AVM generates a run-time error.

The receiving Client-principal object must be unsealed. If not, the AVM generates a run-time
error.

If you set properties on the receiving Client-principal object handle before calling this method,
either by having previously imported the object or by setting them individually, the property
values are lost.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

You can use the imported Client-principal object to set a user ID using either the
SET-CLIENT( ) method or SET-DB-CLIENT function.

Calling this method does not generate an audit event or an audit record.

The following code fragment illustrates how to use the IMPORT-PRINCIPAL( ) method:

```
DEFINE VARIABLE hCP AS HANDLE NO-UNDO.
DEFINE VARIABLE raw-cp AS RAW NO-UNDO.
. . .
CREATE CLIENT-PRINCIPAL hCP.
. . .
hCP:IMPORT-PRINCIPAL(raw-cp).
```

See also: EXPORT-PRINCIPAL( ) method, SET-CLIENT( ) method,
SET-DB-CLIENT function

INCREMENT-EXCLUSIVE-ID( ) method

Gets the amount by which to increment the exclusive ID of a Web request for state-aware
agents. Do not access this method.
INDEX attribute

The subscript value of the array element referenced by the current widget.

Data type: INTEGER
Access: Readable
Applies to: BROWSE widget (column and cell), COMBO-BOX widget, FILL-IN widget, TEXT widget, TOGGLE-BOX widget

If the widget references a field or variable with no extents (that is, not as an array element), this attribute returns 0.

INDEX-INFORMATION attribute

A character string consisting of a comma-separated list of the index or indexes the query uses at the level of join specified.

Data type: CHARACTER
Access: Readable
Applies to: Query object handle

Syntax

INDEX-INFORMATION ( n )

n

An integer expression that evaluates to the level of join for which you want index information.

If the index or indexes do not have bracketing, the first entry in the list is the CHARACTER string “WHOLE-INDEX,” and the second entry in the list is name of the index.

Before you use INDEX-INFORMATION on a dynamic query, you must prepare the query using the QUERY-PREPARE method.

Before you can use the INDEX-INFORMATION attribute on a static query, you must define the query using the DEFINE QUERY statement’s RCODE-INFORMATION option.

The following example prints out the PREPARE-STRING, analyzes the INDEX-INFORMATION, and prints a list of bracketed and whole-index indexes:
INDEX-INFORMATION( ) method

Returns index information in a comma-separated list for the $i^{th}$ index in the buffer’s table.

The returned comma-separated list consists of the following in the specified order:

- The index name
- Three integer values of value 0 (FALSE) or 1 (TRUE) depending on whether the index is unique, primary or a word index
- The names of the index fields, each followed by a 0 (ascending) or 1 (descending)

Return type: CHARACTER

Applies to: Buffer object handle

Syntax

```
INDEX-INFORMATION(i)
```

$i$

The relative number of the buffer table’s index for which you want information.

When the index argument, $i$, is beyond the number of indices in the table or is otherwise invalid, the Unknown value (?) is returned.

The following code fragment requests information about the third index in the customer table:

```
buffCustHdl = BUFFER Customer:HANDLE.
IndexVar = buffCustHdl:INDEX-INFORMATION(3).
```
The returned string would look like: “CustNum,1,1,0,CustNum,0” which means that the third index in the Customer table is called “CustNum”. It is unique and primary, and is not a word index and it consists of one ascending component, CustNum.

**INHERIT-BGCOLOR attribute**
*(Graphical interfaces only)*

Indicates whether field-level widgets inherit the background color of their containing dialog-box or frame widget.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** DIALOG-BOX widget, FRAME widget, SESSION system handle

The default value is TRUE. That is, field-level widgets inherit the background color of the containing dialog-box or frame widget, by default.

When set to FALSE for a dialog-box or frame widget, the following field-level widgets will not inherit the background color of their containing widget: BROWSE, COMBO-BOX (all types), EDITOR, FILL-IN (NATIVE and Enabled), and SELECTION-LIST.

You must set this attribute before realizing the dialog-box or frame widgets.

For static dialog-box and frame widgets, you can also change the default background color inheritance on a frame-by-frame basis by specifying the INHERIT-BGCOLOR option in the Frame phrase when you define the widget.

You can also set this attribute to FALSE on the SESSION system handle to change the default background color inheritance for all dialog-box and frame widgets in the session. Setting this attribute affects dialog-box and frame widgets created only after the attribute is set; it does not affect existing widgets.

**Note:** If you set this attribute on the SESSION system handle in a procedure that also contains static dialog-box or frame widget definitions, the static widgets will not be affected by the attribute setting because they are created before the procedure begins executing. For this reason, Progress Software Corporation recommends that you set this attribute on the SESSION system handle in an initialization procedure that does not contain static widget definitions.

Setting the BGCOLOR attribute for a field-level widget within the dialog-box or frame overrides any INHERIT-BGCOLOR attribute or option settings.

**See also:** BGCOLOR attribute, Frame phrase, INHERIT-FGCOLOR attribute

**INHERIT-FGCOLOR attribute**
*(Graphical interfaces only)*

Indicates whether field-level widgets inherit the foreground color of their containing dialog-box or frame widget.
**INITIAL attribute**

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** DIALOG-BOX widget, FRAME widget, SESSION system handle

The default value is TRUE. That is, field-level widgets inherit the foreground color of the containing dialog-box or frame widget, by default.

When set to FALSE for a dialog-box or frame widget, the following field-level widgets will not inherit the foreground color of their containing widget: BROWSE, COMBO-BOX (all types), EDITOR, FILL-IN (NATIVE and Enabled), and SELECTION-LIST.

You must set this attribute before realizing the dialog-box or frame widgets.

For static dialog-box and frame widgets, you can also change the default foreground color inheritance on a frame-by-frame basis by specifying the INHERIT-FGCOLOR option in the Frame phrase when you define the widget.

You can also set this attribute to FALSE on the SESSION system handle to change the default foreground color inheritance for all dialog-box and frame widgets in the session. Setting this attribute affects dialog-box and frame widgets created only after the attribute is set; it does not affect existing widgets.

**Note:** If you set this attribute on the SESSION system handle in a procedure that also contains static dialog-box or frame widget definitions, the static widgets will not be affected by the attribute setting because they are created before the procedure begins executing. For this reason, Progress Software Corporation recommends that you set this attribute on the SESSION system handle in an initialization procedure that does not contain static widget definitions.

Setting the FGCOLOR attribute for a field-level widget within the dialog-box or frame overrides any INHERIT-FGCOLOR attribute or option settings.

**See also:** FGCOLOR attribute, Frame phrase, INHERIT-BGCOLOR attribute

**INITIAL attribute**

The value of the INITIAL schema field (which is always CHARACTER), formatted with the buffer-field’s format. If the INITIAL schema field has the Unknown value (?), the value of the INITIAL attribute is the null string (“”).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** Buffer-field object handle  
**See also:** DEFAULT-STRING attribute, DEFAULT-VALUE attribute

**INITIALIZE-DOCUMENT-TYPE( ) method**

Creates a new XML document, initializes the document based on the referenced DTD, and creates its root node.
INITIALIZE-DOCUMENT-TYPE( ) method

Return type: LOGICAL
Applies to: X-document object handle

Syntax

```
INITIALIZE-DOCUMENT-TYPE( namespace-uri , root-node-name , public-id ,
               system-id )
```

**namespace-uri**

A character expression representing the namespace Uniform Resource Identifier (URI) you want associated with the root node of the XML document. The `namespace-uri` must be unique and persistent.

**root-node-name**

A character expression representing the name of the root node as defined in the XML document. If you are using namespaces and you want to associate a prefix with the namespace, you must qualify this node name with the `namespace-uri` and a colon character prefix (for example, `namespace-uri:root-node-name`). You must explicitly set the xmlns attribute on the root node.

**public-id**

An optional character expression representing the public ID of the DTD. Currently, there is no way to retrieve a DTD based on a public ID.

**system-id**

A required character expression representing the system ID of the DTD. This contains the path to the DTD which is either a file system path or an HTTP URL. The ABL parser uses this information to retrieve the DTD when parsing the document.

The following example initializes an X-DOCUMENT with a DTD reference and adds the proper namespace declaration, if the namespace URI is not empty:

```
DEFINE INPUT  PARAMETER namespaceURI AS CHARACTER NO-UNDO.
DEFINE INPUT  PARAMETER rootNodeName AS CHARACTER NO-UNDO.
DEFINE INPUT  PARAMETER publicId AS CHARACTER NO-UNDO.
DEFINE INPUT  PARAMETER systemId AS CHARACTER NO-UNDO.
DEFINE OUTPUT PARAMETER hDocument AS HANDLE NO-UNDO.
DEFINE VARIABLE hNsDecl AS HANDLE NO-UNDO.
DEFINE VARIABLE hRootNode AS HANDLE NO-UNDO.
DEFINE VARIABLE errStat AS LOGICAL NO-UNDO.
DEFINE VARIABLE found AS INTEGER NO-UNDO.
```
INITIATE() method

Initializes the Debugger, but does not pass control to the Debugger immediately. To start the Debugger from the procedure in application mode, you must set a breakpoint using the SET-BREAK() method that the procedure encounters. When the procedure encounters the breakpoint, the Debugger takes control of the procedure at that point.

```lisp
/* Create X-DOCUMENT and initialize it. */
CREATE X-DOCUMENT hDocument.
errStat = hDocument:INITIALIZE-DOCUMENT-TYPE
(namespaceURI, rootNodeName, publicId, systemId).
IF NOT errStat THEN DO:
    DELETE OBJECT hDocument.
    LEAVE.
END.

/* If using namespaces, create X-NODEREF for namespace declaration. */
IF LENGTH(namespaceURI) > 0 THEN DO:
    CREATE X-NODEREF hNsDecl.
    CREATE X-NODEREF hRootNode.

/* Look for a colonized name in rootNodeName. */
found = INDEX(rootNodeName, ":").
IF found > 0 THEN DO:
    /* Namespace declarations are special kinds of attributes that belong in
     * the http://www.w3.org/2000/xmlns/ namespace. */
    errStat = hDocument:CREATE-NODE-NAMESPACE(hNsDecl, 
        "http://www.w3.org/2000/xmlns/", "xmlns:" +
        SUBSTRING(rootNodeName, 1, found - 1), "attribute").
END.
ELSE DO:
    /* Use the default namespace, which does not need a namespace declaration
     * prefix, assign it to the http://www.w3.org/2000/xmlns/ namespace. */
    errStat = hDocument:CREATE-NODE-NAMESPACE(hNsDecl, 
        "http://www.w3.org/2000/xmlns/", "xmlns", "attribute").
END.
IF NOT errStat THEN LEAVE.

/* Set the value of the namespace attribute to the namespace URI. */
hNsDecl:NODE-VALUE = namespaceURI.

/* Retrieve the root node and add the namespace declaration to it. */
IF NOT errStat THEN LEAVE.
    errStat = hRootNode:SET-ATTRIBUTE-NODE(hNsDecl).
END.

/* Free up the temporary X-NODEREFs. */
IF VALID-HANDLE(hNsDecl) THEN
    DELETE OBJECT hNsDecl.
IF VALID-HANDLE(hRootNode) THEN
    DELETE OBJECT hRootNode.

/* If an error occurred, free up the X-DOCUMENT. */
IF NOT errStat THEN
    DELETE OBJECT hDocument.
```
INNER-CHARS attribute

The number of data columns within a selection list or editor widget.

Data type: INTEGER
Access: Readable/Writeable
Applies to: EDITOR widget, SELECTION-LIST widget

This attribute is more portable than the WIDTH-CHARS attribute.

For editor widgets, this attribute can set the word wrap margin for the WORD-WRAP attribute. For more information, see the WORD-WRAP attribute reference entry.

If a selection list is not already realized and you reference its INNER-CHARS attribute, the AVM realizes the widget.

INNER-LINES attribute

The number of data lines within a combo-box drop down list, editor widget, or selection list.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget (column), COMBO-BOX widget, EDITOR widget, SELECTION-LIST widget

For combo boxes, this attribute has meaning only in Windows.

This attribute is more portable than the HEIGHT-CHARS attribute. For combo boxes, the value must be 3 or greater.

Return type: LOGICAL
Applies to: DEBUGGER system handle

Syntax

INITIATE ( )

If the INITIATE( ) method successfully initializes the Debugger or the Debugger is already initialized, the method returns TRUE. Otherwise, it returns FALSE with no effect.

Note: To use this method, the Application Debugger must be installed.

All other Debugger attributes and methods (except the DEBUG( ) method) have no effect unless you first initialize the Debugger with this method or start the Debugger from the OpenEdge ADE. If the Debugger is already initialized and running (for example, by running ABL with the -debug startup parameter), this method has no effect.
If a selection list or combo box is not already realized and you reference its INNER-LINES attribute, the AVM realizes the widget.

For browses, this attribute applies only to combo-box browse columns.

INPUT-VALUE attribute

Used for data-representation widgets, such as field-level widgets that represent variables or database fields. The value for the INPUT-VALUE attribute is the unformatted SCREEN-VALUE of a widget.

Data type: Same as the field or variable associated with the widget
Access: Readable
Applies to: BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget, LITERAL widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

For any widget that has a SCREEN-VALUE, INPUT-VALUE returns the unformatted value of the widget’s SCREEN-VALUE, in the native data type of the widget.

The INPUT-VALUE attribute has the following syntax:

Syntax

```
widget-name:INPUT-VALUE
```

When you use the INPUT-VALUE attribute, there are no formatting characters and the data type is the data type of the associated field. The relationship between a field’s INPUT-VALUE and the value in the record buffer is the same as the relationship between the SCREEN-VALUE and the record buffer. For example, changing the record buffer does not affect the INPUT-VALUE.

When you use the DISPLAY, PUT, or MESSAGE statements for the INPUT-VALUE of a widget that has the DATE data type, you see the formatted value because these statements automatically format DATE values. To display an unformatted date, first assign INPUT-VALUE to an integer variable, and then display the variable.

See also: SCREEN-VALUE attribute

INSERT( ) method

Inserts a new item before a specified item in a combo box or selection list. The new item can consist of a label, a list of labels, or a label-value pair.
**Return type:** LOGICAL

**Applies to:** BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

**Syntax**

```
INSERT (
    { new-item-list  |  new-label , new-value }
    ,
    { list-item      |  list-index }
)
```

- **new-item-list**
  A character-string expression that specifies a single item or a delimiter-separated list of items to add to the widget.

- **new-label**
  A character-string expression that specifies the label of a label-value pair to add to the widget.

- **new-value**
  The new value assigned when a user selects the label.

---

**Note:** If the widget’s entries consist of single items, use `new-item-list`. If the widget’s entries consist of label-value pairs, use `new-label` and `new-value`.

- **list-item**
  A character-string expression that specifies a single value in the widget.

- **list-index**
  An integer expression that specifies the ordinal position of an existing entry in the widget.
  The first item is specified by 0 and the last item is specified by -1.

The delimiter is the value of the DELIMITER attribute, which is a comma by default. If the method is successful, it returns TRUE.

For browses, this method applies only to combo-box browse columns.

---

**Note:** If the widget’s entries consist of single items, each call to INSERT can add multiple entries. If the widget’s entries consist of label-value pairs, each call to INSERT can add one entry.

---

**INSERT-ATTRIBUTE( ) method**

For a SAX-writer object, adds a single attribute to a start tag in the XML document represented by the SAX-writer object. For a SAX-attributes object, inserts an attribute and its value into the SAX-attributes object.
**Caution:** The SAX specifications specifically state that the order of attributes in an XML element’s list are not guaranteed.

**Return type:** LOGICAL

**Applies to:** SAX-attributes object handle, SAX-writer object handle

**Syntax**

```
INSERT-ATTRIBUTE( attribute-name, attribute-value [, namespaceURI ] )
```

**attribute-name**

A CHARACTER or LONGCHAR expression evaluating to the fully qualified or unqualified name of the attribute.

**attribute-value**

A CHARACTER or LONGCHAR expression evaluating to the value of the attribute.

**namespaceURI**

A CHARACTER or LONGCHAR expression evaluating to:

- The URI of the attribute
- A zero-length string
- The Unknown value (?) if the attribute doesn’t contain a namespace

**SAX-writer object handle usage**

Call this method to add a simple, single attribute to a start tag. You can only call this method immediately after a call to the START-ELEMENT, EMPTY-ELEMENT, INSERT-ATTRIBUTE, or DECLARE-NAMESPACE method. That is, you can only call this method when the WRITE-STATUS is SAX-WRITE-TAG. After calling this method, the status remains SAX-WRITE-TAG.

The STRICT attribute setting determines if the XML output for a SAX-writer object is well formed. However, regardless of the value of the STRICT attribute, this method fails if you do not call it following one of the methods listed in the previous paragraph.

**SAX-attributes object handle usage**

Call this method to add an attribute to a SAX-attributes object. If there are already attributes in the SAX-attributes object, then the new attribute is added to the end of the list. For example, if the SAX-attributes object has three attributes, then the NUM-ITEMS attribute value will be 3. After calling this method, NUM-ITEMS will be 4 and the new attribute will be located at index position 4.

You can use this method to populate a new SAX-attributes object from scratch. For example, if all the XML elements in a particular document have a default set of attributes, you can create one SAX-attributes object to hold the default set and reuse that SAX-attributes object when writing each XML element.
No validation is done on inserted data. Care must be taken to not enter duplicate attribute names. Non-unique attribute names prevent XML from being validated as well-formed XML. Such a result will cause an error with the SAX-writer object during writing operations if the STRICT attribute is set to TRUE.

**Caution:** Use the UPDATE-ATTRIBUTE() to change attribute values. Using the INSERT-ATTRIBUTE() method with an attribute name that already exists in a SAX-attributes object results in duplicate attribute names. The resulting XML is not well-formed and may fail validation within ABL applications and within third-party XML-enabled applications.

### Namespace declarations with attributes

Namespace declarations appear as attributes in an XML document. You can declare a namespace by using the INSERT-ATTRIBUTE() method instead of using the SAX-writer object’s DECLARE-NAMESPACE() method. To do this, you must use the special prefix for namespaces, xmlns, with the name of the attribute, and the namespaceURI must be the value of the attribute.

```plaintext
swh:START-ELEMENT("prefix:name").
swh:INSERT-ATTRIBUTE("xmlns:prefix", "target.url").
swh:END-ELEMENT("prefix:name").
```

The previous example is equivalent to the following example, which uses the traditional method:

```plaintext
swh:START-ELEMENT("prefix:name").
swh:DECLARE-NAMESPACE("target.url", "prefix").
swh:END-ELEMENT("prefix:name").
```

Namespaces declared using the INSERT-ATTRIBUTE() method in this way are considered valid namespaces and will be included in namespace checking during the XML write operation. If the xmlns prefix does not appear, then the attribute is inserted as a regular attribute and it is not handled with the namespace checking during the XML write operation.

Similarly, namespaces that appear as such in a SAX-attributes object will also generate the appropriate namespace.

If you use namespaceURI, then the method resolves the prefix in the following order:

- It attempts to extract the namespace from attribute-name.
- It attempts to extract the namespace from a previously declared namespace.

If the method call only contains name and that value contains a prefix, then the SAX-writer attempts to resolve the prefix to a namespace. If it fails to resolve the namespace and the STRICT attribute is TRUE, then the method fails.

The following is a SAX-attributes object example:
**INSERT-BACKTAB( ) method**

(Character interfaces only)

Moves the cursor backward to the previous four-space tab stop without affecting the text in the widget.

**Return type:** LOGICAL

**Applies to:** EDITOR widget

**Syntax**

```
INSERT-BACKTAB ( )
```

If the operation is successful, the method returns TRUE.

---

**INSERT-BEFORE( ) method**

Insert a node as a child of this document before another node (or last if the other node is unknown). This is one way to place the node into the document structure after the node has been created with the CREATE-NODE( ) or CREATE-NODE-NAMESPACE( ) method, cloned with the CLONE-NODE( ) method, or removed with the REMOVE-NODE( ) method. (Similar to the APPEND-CHILD( ) method.)

**Return type:** LOGICAL

**Applies to:** X-document object handle, X-noderef object handle

**Syntax**

```
INSERT-BEFORE(  x-ref-handle1 ,  x-ref-handle2  )
```

*x-ref-handle1*

The handle that represents the node to insert as a child of this document.

*x-ref-handle2*

A handle that represents the XML node that the node is to be inserted before. If unknown, the node will be appended as the last child.

The following code fragment demonstrates the use of the INSERT-BEFORE( ) method.

```
DEFINE VARIABLE hSAX-attributes AS HANDLE NO-UNDO.
CREATE SAX-ATTRIBUTES hSAX-attributes.

hSAX-attributes:INSERT-ATTRIBUTE( "language", "EN" ). /* index = 1 */

hSAX-attributes:INSERT-ATTRIBUTE( "year", "2006" ). /* index = 2 */
```

**See also:** DECLARE-NAMESPACE( ) method, REMOVE-ATTRIBUTE( ) method, UPDATE-ATTRIBUTE( ) method
**INSERT-FILE( ) method**

Inserts the text of *filename* into the editor widget at the current location of the text cursor.

**Return type:** LOGICAL

**Applies to:** EDITOR widget

**Syntax**

```
INSERT-FILE ( filename )
```

*filename*

A character-string expression equal to the full or relative pathname of a file. If you specify a relative pathname, the INSERT-FILE( ) method searches PROPATH to find the file.

If the text insertion is successful, the method returns TRUE.

**Note:** This method replaces each horizontal tab character with eight spaces as it inserts the text into the widget.

---

**INSERT-ROW( ) method**

Inserts a blank line in an updateable browse before or after the last selected row. The blank line is a placeholder for a new record to be added through the browse. This method cannot be used with a read-only browse.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
INSERT-ROW ( BEFORE | AFTER )
```

**BEFORE**

Adds a new row before the current browse row. This is the default.

**AFTER**

Adds a new row after the current browse row.
**INSERT-STRING( ) method**

Inserts a string into the editor widget at the current location of the text cursor.

**Return type:** LOGICAL  
**Applies to:** EDITOR widget

**Syntax**

```plaintext
INSERT-STRING ( string )
```

*string*

A character string expression.

If the operation is successful, the method returns TRUE.

---

**INSERT-TAB( ) method**  
*(Character interfaces only)*

This method works differently depending on the insert mode status. If insert mode is on, it
inserts one to four spaces from the current cursor position to the next four-space tab stop. If
insert mode is off, it moves the cursor to the next four-space tab stop without inserting any
characters.

**Return type:** LOGICAL  
**Applies to:** EDITOR widget

**Syntax**

```plaintext
INSERT-TAB ( )
```

If the operation is successful, the method returns TRUE.

---

**INSTANTIATING-PROCEDURE attribute**

Returns the handle to the procedure in which an object was instantiated.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** ACTIVE-WINDOW system handle, Asynchronous request object handle, AUDIT-CONTROL system handle, AUDIT-POLICY system handle, BROWSE widget (browse and column), Buffer object handle, Buffer-field object handle, BUTTON widget, Call object handle, Client-principal object handle, CLIPBOARD system handle, CODEBASE-LOCATOR system handle, COLOR-TABLE system handle, COMBO-BOX widget, COMPILER system handle, CONTROL-FRAME widget, CURRENT-WINDOW system handle, Data-relation object handle, Data-source object handle, DEBUGGER system handle,
When applied to a widget or object handle, this attribute always returns a handle. This handle is either valid or invalid based on the state of the instantiating procedure. The instantiating procedure for a dynamically created object might no longer be running. In this case, the handle is invalid.

**Note:** Since you can never be sure of the state of an instantiating procedure, never use this attribute as a chained attribute.

In general, INSTANTIATING-PROCEDURE returns the procedure handle for the procedure in which the DEFINE or CREATE statement is executed. Following are the exceptions:

- For a procedure handle or an asynchronous request object handle, INSTANTIATING-PROCEDURE returns the procedure handle for the procedure from which the RUN statement was executed.

- For a socket handle created on a socket server after a CONNECT statement, INSTANTIATING-PROCEDURE returns the procedure handle for the procedure in which the socket server connect procedure is defined.

- For a temp-table handle that is passed from a client to an Appserver, INSTANTIATING-PROCEDURE returns the procedure handle for the first procedure run on the AppServer.

- For a temp-table handle that is received from an AppServer by a client, INSTANTIATING-PROCEDURE returns the procedure handle for the procedure that called the AppServer.

- For implicitly created handles, INSTANTIATING-PROCEDURE returns the procedure handle where the implicitly created object is returned (such as the SAX-attributes object in theStartElement callback).

- For the COM-SELF system handle, which is not a widget handle, INSTANTIATING-PROCEDURE returns a run-time error.
INTERNAL-ENTRIES attribute

Although this attribute applies to all widgets and handles, not all system handles are associated with an instantiating procedure and do not return a procedure handle. For these system handles, this attribute returns the Unknown value (?). The following system handles always return the Unknown value (?):

<table>
<thead>
<tr>
<th>SYSTEM HANDLE</th>
<th>SYSTEM HANDLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIPBOARD system handle</td>
<td>CODEBASE-LOCATOR system handle</td>
</tr>
<tr>
<td>COLOR-TABLE system handle</td>
<td>COMPILER system handle</td>
</tr>
<tr>
<td>DEBUGGER system handle</td>
<td>DSLOG-MANAGER system handle</td>
</tr>
<tr>
<td>ERROR-STATUS system handle</td>
<td>FILE-INFO system handle</td>
</tr>
<tr>
<td>FOCUS system handle</td>
<td>FONT-TABLE system handle</td>
</tr>
<tr>
<td>LAST-EVENT system handle</td>
<td>LOG-MANAGER system handle</td>
</tr>
<tr>
<td>RCODE-INFO system handle</td>
<td>SESSION system handle</td>
</tr>
<tr>
<td>WEB-CONTEXT system handle</td>
<td>–</td>
</tr>
</tbody>
</table>

INTERNAL-ENTRIES attribute

A comma-separated list containing the names of all internal procedures and user-defined functions defined in the procedure associated with the specified handle. Returns the Unknown value (?) for a Web service procedure or proxy persistent procedure.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** Procedure object handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

If you supply a handle to a procedure that defines no internal procedures or user-defined functions, the value of INTERNAL-ENTRIES is the null string (""").

For more information on proxy handles and remote procedures, see *OpenEdge Application Server: Developing AppServer Applications*.

**Note:** The list provided by INTERNAL-ENTRIES does not contain the name of any internal procedure defined using the PROCEDURE statement’s PRIVATE option. Similarly, the list does not contain the name of any user-defined function defined using the FUNCTION statement’s PRIVATE option. However, if the procedure object handle is equal to THIS-PROCEDURE, INTERNAL-ENTRIES returns all internal procedures and user-defined functions, including those defined as PRIVATE.

**INVOKE( ) method (Handle)**

Lets you do the following dynamically:
INVOKE( ) method (Handle)

- Invoke an external procedure, internal procedure, or user-defined function
- Invoke a Windows DLL routine or Unix shared library routine
- Get or set an object handle attribute
- Run an object handle method

**Return type:** None (Similar to the RUN statement.)

**Applies to:** Call object handle

**Syntax**

```
INVOKE( )
```

To determine what action to take, INVOKE( ) examines the CALL-NAME and CALL-TYPE attributes.

Before you execute INVOKE( ), you must set the CALL-NAME attribute.

Table 83 describes what INVOKE( ) does for each call type.

**Table 83: What INVOKE( ) does for each call type**

<table>
<thead>
<tr>
<th>For this call type . . .</th>
<th>INVOKE( ) . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCEDURE-CALL-TYPE (the default)</td>
<td>Follows the rules of the RUN statement to determine what to invoke and whether to invoke external or internal procedures.</td>
</tr>
<tr>
<td>FUNCTION-CALL-TYPE</td>
<td>Follows the rules of the DYNAMIC-FUNCTION function.</td>
</tr>
</tbody>
</table>
| GET-ATTR-CALL-TYPE | Follows the rules of `widget:attribute`.  
**Note:** The IN-HANDLE attribute must be set before INVOKE( ) is executed. |
| SET-ATTR-CALL-TYPE | Sets the attribute specified by the CALL-NAME attribute to the first parameter specified by the SET-PARAMETER( ) method.  
**Note:** The IN-HANDLE attribute must be set before INVOKE( ) is executed. |

If the PERSISTENT attribute is TRUE (which is valid only for invoking an external procedure), the procedure runs persistently, and when INVOKE( ) returns, IN-HANDLE contains a handle to the persistent procedure.

Before you dynamically invoke an external procedure that is remote—that is, one that resides on an AppServer—you must set the SERVER attribute to the handle of the AppServer.

When INVOKE( ) starts executing, it examines the NUM-PARAMETERS attribute. If NUM-PARAMETERS is nonzero, INVOKE( ) uses each parameter set by the SET-PARAMETER( ) method, even one set during a previous use of the call object.
IN-HANDLE attribute

A handle to one of the following:

- A persistent procedure you just started up dynamically (by invoking an external procedure with the PERSISTENT attribute set to TRUE)
- A running persistent procedure containing an internal procedure or user-defined function you want to invoke dynamically
- An object whose attributes you want to get or set dynamically, or whose methods you want to run dynamically

Data type: HANDLE
Access: Readable/Writable
Applies to: Call object handle

Syntax

```
IN-HANDLE [ = \{ handle-expression | char-expression \} ]
```

handle-expression

A HANDLE expression. Table 84 explains what the handle can indicate and who it is set by.

---

**Note:** To clear all parameters, even those set during a previous use of the call object, set the NUM-PARAMETERS attribute to zero.

No parameters are evaluated during INVOKE( ) processing. Parameters are evaluated only during SET-PARAMETER( ) processing.

When the invoked routine starts, if any parameter indicated by the NUM-PARAMETERS attribute has not been set, you will get an error message.

For more information on INVOKE( ), see the reference entries for the RUN statement and the DYNAMIC-FUNCTION function.

**Note:** INVOKE( ) cannot occur within an expression.
**Table 84: What IN-HANDLE indicates and who sets it**

<table>
<thead>
<tr>
<th>If the handle indicates . . .</th>
<th>It is set by . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>A persistent procedure you just started up dynamically</td>
<td>The INVOKE( ) method</td>
</tr>
<tr>
<td>An already-running persistent procedure containing logic (in the form of internal procedures and user-defined functions) you want to invoke dynamically</td>
<td>You</td>
</tr>
<tr>
<td>An object whose attributes you want to get or set dynamically</td>
<td>You</td>
</tr>
</tbody>
</table>

*char-expression*

A CHARACTER expression indicating the name of a system object, such as "SESSION" or "FILE-INFO".

The default is the Unknown value (?)

When you use IN-HANDLE to call an internal procedure, IN-HANDLE affects INVOKE( ) the same way the IN proc-handle phrase affects the RUN statement. Similarly, when you use IN-HANDLE to call a user-defined function, it affects INVOKE( ) the same way the IN proc-handle phrase affects the DYNAMIC-FUNCTION function. In both cases, IN-HANDLE specifies the instance of the external procedure that contains the internal procedure or user-defined function.

When IN-HANDLE is used to get or set an attribute or to invoke a method, it represents a handle to the object to which the attribute applies. If the attribute applies to a system object such as the SESSION handle or the FILE-INFO handle, IN-HANDLE can be set to a character string such as "SESSION" or "FILE-INFO" that indicates the name of the system object.

**Note:** When you create a running persistent procedure by running an external procedure persistently, you can do this statically or dynamically. Similarly, you can run any of the persistent procedure’s internal procedures and user-defined functions statically or dynamically.

For information on dynamically invoking logic that resides on an AppServer, see the reference entry for SERVER attribute.

**IS-CLASS attribute**

Indicates whether an r-code file defines a class or a procedure.
IS-OPEN attribute

Indicates whether a transaction or query object is open.

Data type: LOGICAL
Access: Readable
Applies to: Query object handle, Transaction object handle

The IS-OPEN attribute is TRUE if the specified database transaction or query object is active.
For transaction handles, this attribute is identical to the TRANSACTION function.

IS-PARAMETER-SET attribute

Indicates whether you have already set a particular parameter.

Data type: LOGICAL
Access: Readable
Applies to: Call object handle

Syntax

\[
\text{IS-PARAMETER-SET}(\text{parameter-number})
\]

\text{parameter-number}

An integer expression indicating the order of the parameter, where 1 represents the first parameter, 2 represents the second parameter, and so on.

If the parameter is set, IS-PARAMETER-SET returns TRUE. Otherwise, it returns FALSE. The default is FALSE.

IS-ROW-SELECTED( ) method

Returns TRUE if a specified row in the browse viewport is currently selected.
IS-SELECTED( ) method

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
IS-ROW-SELECTED ( n )
```

- **n**
  - An integer expression that specifies a selected row within the browse viewport.

The AVM maintains a numbered list of selected rows, starting at 1.

### IS-SELECTED( ) method

Returns TRUE if a specified item in a selection list is currently selected. Otherwise, the method returns FALSE.

- **Return type:** LOGICAL
- **Applies to:** SELECTION-LIST widget

**Syntax**

```
IS-SELECTED ( list-item | list-index )
```

- **list-item**
  - A character-string expression that specifies a single value in the selection list.

- **list-index**
  - An integer expression that specifies the ordinal position (first, second, third, etc.) of an entry in the selection-list.
IS-JSON attribute

Returns whether a JSON string was posted to the transaction server. The AVM determines the value by checking if the content-type HTTP header is either "application/json" or "text/json".

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** WEB-CONTEXT system handle

IS-XML attribute

Returns whether an XML document was posted to the transaction server.

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** WEB-CONTEXT system handle

ITEMS-PER-ROW attribute

How to format multiple items written to the system clipboard using the CLIPBOARD handle.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** CLIPBOARD system handle

This attribute has meaning only when the CLIPBOARD:MULTIPLE attribute is TRUE, and has no effect when reading data from the clipboard. For more information, see the reference entry for the CLIPBOARD system handle.

KEEP-CONNECTION-OPEN attribute

Indicates whether WebClient should keep any server connection, that it creates, open after downloading a file (TRUE) or not (FALSE).

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** CODEBASE-LOCATOR system handle

KEEP-FRAME-Z-ORDER attribute

The overlay order of the frames in a window.
**KEEP-SECURITY-CACHE attribute**

Indicates whether WebClient saves the values of the attributes in the security cache between sessions (TRUE) or not (FALSE), as requested by the user. The default value is FALSE.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** CODEBASE-LOCATOR system handle

The following attributes represent the security cache:

- APPSERVER-INFO
- APPSERVER-PASSWORD
- APPSERVER-USERID
- URL-PASSWORD
- URL-USERID
- KEEP-SECURITY-CACHE

These attributes are readable and writeable.

**KEY attribute**

Indicates whether the field corresponding to a buffer-field participates in an index.
**KEYS attribute**

Returns a comma-separated list of key fields for a buffer.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** Buffer object handle, Data-source object handle

For a Data-source object buffer, this attribute returns a comma-separated list of key fields defined in an associated KEYS clause for the specified buffer. If there are no defined key fields, this attribute returns a comma-separated list of key fields in the buffer’s unique primary index (if any). If there are no defined key fields and no unique primary index, this attribute returns the string "ROWID".

Following is the syntax for accessing this attribute for a Data-source object buffer:

**Syntax**

```
data-source-handle:KEYS( buffer-sequence-number )
```

**Note:** Sequence numbers for buffers of a query start at one, where one represents the top level and subsequent numbers represent lower levels of join, if any.

Following is the syntax for accessing this attribute for a buffer directly:

**Syntax**

```
buffer-handle:KEYS
```

**buffer-handle**

The handle to the buffer.
**LABEL attribute**

The label of a widget or the name of a low-level event.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (column), Buffer-field object handle, BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, MENU-ITEM widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, LAST-EVENT system handle

For the LAST-EVENT handle, this attribute is readable only.

For a widget, the LABEL attribute specifies the label for the widget. For some data representation widgets, it is actually the SCREEN-VALUE attribute value of the literal or text widget that is assigned to the SIDE-LABEL-HANDLE attribute of the specified data representation widget. For more information, see the SIDE-LABEL-HANDLE attribute reference entry.

For the LAST-EVENT handle, the LABEL attribute returns the names of low-level events based on the EVENT-TYPE attribute value. For EVENT-TYPE = "KEYPRESS", this attribute returns key label events, such as "F1" or "ESC". It also returns the key labels of any keys that trigger key function events (returned by the FUNCTION attribute).

For EVENT-TYPE = "MOUSE", this attribute returns low-level events for both portable and three-button mouse event types, such as "SELECT-MOUSE-UP" (portable) or "LEFT-MOUSE-UP" (three-button). It also returns the names of the low-level mouse actions that trigger any high-level mouse events (returned by the FUNCTION attribute).

For EVENT-TYPE = "PROGRESS", this attribute returns the same high-level event name returned by the FUNCTION attribute unless the ABL event is triggered by a key press. In this case, it returns the key label of the key that triggered the event.

**Note:** When the AUTO-RESIZE attribute is set to TRUE, the AVM resizes button and toggle-box widgets with run-time changes to the LABEL attribute.

**LABEL-BGCOLOR attribute**

The color number of the background color for a column label or all column labels in a browse widget.
**LABEL-DCOLOR attribute**

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget (browse and column)

**LABEL-DCOLOR attribute (Character interfaces only)**

The color number of the display color for a column label or all column labels in a browse widget.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget (browse and column)

**LABEL-FGCOLOR attribute**

The color number of the foreground color for a column label or all column labels in a browse widget.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget (browse and column)

**LABEL-FONT attribute**

The font for a column label or all column labels in a browse widget.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget (browse and column)

**LABELS attribute**

Indicates whether a label appears with the widget.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, TEXT widget

This attribute applies to static frames.
This attribute is writeable for the browse widget only. If the LABELS attribute is set to FALSE for a browse widget, no column headers will appear with the browse.

If the LABELS attribute is FALSE for a combo-box, editor, fill-in, or text widget, no label appears with the widget. If the attribute is FALSE for a frame, the NO-LABELS option is specified in the frame phrase for the frame and no labels are displayed with field-level widgets within the frame.

**LANGUAGES attribute**

A comma-separated list of all languages compiled into the r-code file specified by the RCODE-INFO:FILE-NAME attribute.

- **Data type:** CHARACTER
- **Access:** Readable
- **Applies to:** RCODE-INFO system handle

If the r-code file was compiled with only the default language, LANGUAGES returns an empty string.

**LARGE attribute**

*(Windows only; Graphical interfaces only)*

Indicates whether a Windows editor widget can hold 32K of text. Non-Windows platforms ignore this attribute.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** EDITOR widget

When LARGE is FALSE, the Windows editor widget can hold 32K of text. When LARGE is TRUE, the Windows editor widget can hold over 64K of text—the precise limit depends on available resources.

You can set this attribute only before the editor widget is realized.

**Note:** In character interfaces, the editor widget can hold large amounts of text by default. Therefore, character interfaces do not need separate “large” and “small” editors.

**LARGE-TO-SMALL attribute**

The default numeric range that a slider can display is small (minimum) to large (maximum). The LARGE-TO-SMALL option allows you to override this default behavior as follows:

- When the slider is positioned horizontally, the left-most position on the trackbar displays the maximum value and the right-most position displays the minimum value.
When the slider is positioned vertically, the bottom-most position on the trackbar displays the maximum value and the top-most position displays the minimum value.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SLIDER widget

### LAST-ASYNC-REQUEST attribute

Returns the last entry in the list of all current asynchronous request handles for the specified AppServer or Web service that have been created in the current session.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Server object handle

If there are no asynchronous request handles for the specified server, LAST-ASYNC-REQUEST returns the Unknown value (?).

### LAST-BATCH attribute

Indicates whether a FILL operation on a ProDataSet temp-table retrieved the last batch of rows in its associated query.

**Note:** You typically use the LAST-BATCH attribute in conjunction with the BATCH-SIZE attribute. It is best to use the LAST-BATCH attribute with a top-level ProDataSet temp-table. If you use the LAST-BATCH attribute with the BATCH-SIZE attribute for a child temp-table, the parent (or ancestor) must have only one row, because the AVM restarts the BATCH-SIZE counter on a child temp-table for each parent record (as opposed to once per child temp-table).

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Buffer object handle  
**See also:** BATCH-SIZE attribute, FILL( ) method

### LAST-CHILD attribute

The handle of the last widget created in the container widget or the current session.
LAST-FORM attribute

The object reference for the last .NET form or ABL FormProxy object (Progress.GUI.FormProxy) in the list of all valid form objects created in the current ABL session.

Data type: Progress.Windows.IForm
Access: Readable
Applies to: SESSION system handle

Once you get the last object reference in the list, you can use the PrevForm property in the Progress.Windows.IForm interface to get the previous entry in the list of form object references.

Note: To obtain the last class-based object in the list of all valid ABL and .NET objects created in the current ABL session, use the LAST-OBJECT attribute.

See also: FIRST-OBJECT attribute, LAST-OBJECT attribute, PrevForm property, Progress.Windows.FormProxy class, Progress.Windows.IForm interface

LAST-OBJECT attribute

The object reference for the last class instance in the list of all valid ABL and .NET class instances created in the current ABL session. If there are no class instances in the current session, this attribute returns the Unknown value (?)..

Data type: Progress.Lang.Object
Access: Readable
Applies to: SESSION system handle

Once you get the last object reference in the list, you can use the PREV-SIBLING property in the Progress.Lang.Object class to get the previous entry in the list of ABL and .NET object references.

There are two points worth noting about this attribute with garbage collection enabled:
The object references maintained by the LAST-OBJECT attribute and the PREV-SIBLING property do not count as references for garbage collection. That is, if a class instance is referenced only on the session object chain, it is available for automatic garbage collection.

When an ABL object that inherits from a .NET object is on the session object chain, it can have circular references that prevent it from being deleted (as with pure ABL objects). When there are no more ABL references to such an ABL-derived .NET object, the object is removed from the object chain, but may still be instantiated because of references to it from .NET. If the application re-obtains a reference to the object in ABL by getting it from .NET, the reference is again placed on the object chain.

Note: To obtain the last .NET form or ABL FormProxy object in the list of all valid form objects created in the current ABL session, use the LAST-FORM attribute.

See also: FIRST-OBJECT attribute, LAST-FORM attribute, PREV-SIBLING property, Progress.Lang.Object class

LAST-OF() method

Returns TRUE if the current iteration of the query predicate FOR EACH . . . BREAK BY . . . is the last iteration for a new break group.

Return type: LOGICAL
Applies to: Query object handle

Syntax

```
LAST-OF( level )
```

`level`

An integer expression that indicates a BREAK BY group, where 0 is the entire query, 1 is the first BREAK BY, 2 is the second BREAK BY, and so on.

The following example shows how the LAST-OF() method is used to identify the last record of a break group:
LAST-PROCEDURE attribute

For AppServer, returns a handle to the last entry in the list of remote persistent procedures running on the connected AppServer. For Web services, returns a handle to the last entry in the list of procedure objects associated with the Web service.

Data type: HANDLE
Access: Readable
Applies to: Server object handle, SESSION system handle

If the current session has no active persistent procedures or the AppServer has no active remote persistent procedures, LAST-PROCEDURE returns the Unknown value (?). To find the previous persistent procedure given the last, access the PREV-SIBLING attribute of the procedure handle you just got.

For information on creating persistent procedures, see the RUN statement reference entry. For more information on the AppServer, see OpenEdge Application Server: Developing AppServer Applications. To check a handle for validity, use the VALID-HANDLE function.

LAST-SERVER attribute

A handle to the last entry in the list of server handles for the current ABL session. This includes both AppServer server objects and Web service server objects.
LAST-SERVER-SOCKET attribute

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

Returns the handle associated with the last entry in the list of all server handles created in the current session. If the current session has no server handles, LAST-SERVER has the Unknown value (?). For more information on server handles, see the Server object handle reference entry.

LAST-SERVER-SOCKET attribute

A handle to the last entry in the list of all valid server socket handles created in the current session. If there are no server socket handles in this session, LAST-SERVER-SOCKET returns the Unknown value (?).

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

LAST-SOCKET attribute

A handle to the last entry in the list of all valid socket handles created in the current session. If there are no socket handles in this session, LAST-SOCKET returns the Unknown value (?).

Data type: HANDLE
Access: Readable
Applies to: SESSION system handle

LAST-TAB-ITEM attribute

The last widget in the tab order of a field group.

Data type: HANDLE
Access: Readable/Writeable
Applies to: FIELD-GROUP widget

When you set this attribute, the assigned widget is moved to the last tab position, following the widget that was previously at this position. Other widgets in the field group maintain their same relative tab positions.

To set the attribute, you must assign it the handle of a field-level widget or frame that can receive focus from a TAB event and that is also a child of the field group to which the attribute applies. If the LAST-TAB-ITEM attribute is not set (is the Unknown value (?)), the default last tab position goes to the widget identified by the LAST-CHILD attribute of the field group.

For more information on how frames owned by a field group participate in the tab order of that field group, see the FRAME widget reference entry.
Left property
(Windows only; Graphical interfaces only)

The horizontal position of the control-frame and control-frame COM object from the left side of the parent container widget, in pixels.

**Return type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** CONTROL-FRAME widget, COM object

Setting this value changes the COLUMN attribute and X attribute of the corresponding control-frame widget to an equivalent value.

**Note:** References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

LENGTH attribute

The length (number of characters) of the current content of the editor widget.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** EDITOR widget

If the editor widget is not already realized and you reference its LENGTH attribute, the AVM realizes the widget.

In Windows, both the regular editor and the large editor support LENGTH.

LIBRARY attribute

Specifies the name of a Windows Dynamic Link Library (DLL) or a UNIX shared library.
**LIBRARY-CALLING-CONVENTION attribute**

**Data type:** CHARACTER  
**Access:** Readable/Writable  
**Applies to:** Call object handle

This attribute is required for dynamic invocation of a DLL or shared library. The AVM verifies the validity and existence of the LIBRARY value at run time when the call object’s INVOKE( ) method is called.

If LIBRARY specifies a full path name, the AVM searches only that path for the shared library. Otherwise, the AVM first determines if the shared library is loaded in memory. If it is not loaded in memory, the AVM looks for the shared library in the current working directory. If the shared library cannot be found at this point:

- **On Windows** the AVM uses the standard Windows search algorithm to find the DLL, the same algorithm used to find Windows executable (.exe) files.
- **On UNIX** the AVM continues searching for the shared library using the ABL PROPATH.

**See also**  
INVOKE( ) method (Handle)

### Table 85: Valid LIBRARY-CALLING-CONVENTION attribute values

<table>
<thead>
<tr>
<th>Keyword constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STDCALL</td>
<td>Use the standard Windows calling convention when accessing the routine. This is the default value.</td>
</tr>
<tr>
<td>CDECL</td>
<td>Use the C calling convention when accessing the routine.</td>
</tr>
</tbody>
</table>

The AVM returns a run-time error if a value other than "CDECL" or "STDCALL" is assigned to this attribute.

**See also**  
INVOKE( ) method (Handle), LIBRARY attribute, ORDINAL attribute
LINE attribute

The current logical line number (iteration number) of the frame.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** FRAME widget

This attribute applies to down frames only.

This attribute is equivalent to the FRAME-LINE function. For more information, see the FRAME-LINE function reference entry.

LIST-ITEM-PAIRS attribute

A list of the label-value pairs associated with a combo box or selection list. The list is delimiter-separated.

**Note:** The LIST-ITEM-PAIRS attribute applies only to combo boxes and selection lists whose entries consist of label-value pairs. For combo boxes and selection lists whose entries consist of single items, use the LIST-ITEMS attribute.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

The value of the delimiter depends on the value of the DELIMITER attribute, which is a comma by default.

For browses, this attribute applies only to combo-box browse columns.

LIST-ITEM-PAIRS provides a list like the following:

"Red,1,Blue,2,Green,3"

LIST-ITEMS attribute

A list of the items associated with a combo box or selection list. The list is delimiter-separated.

**Note:** The LIST-ITEMS attribute applies only to combo boxes and selection lists whose entries consist of single items. For combo boxes and selection lists whose entries consist of label-value pairs, use the LIST-ITEM-PAIRS attribute.
LIST-PROPERTY-NAMES( ) method

Data type: CHARACTER
Access: Readable/Writeable
Applies to: BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

The value of the delimiter depends on the value of the DELIMITER attribute, which is comma by default.

For browses, this attribute applies only to combo-box browse columns.

LIST-ITEMS provides a list like the following:

"Red, Blue, Green"

LIST-PROPERTY-NAMES( ) method

Returns a comma-separated list of all application-defined properties associated with the Client-principal object. The Client-principal object may be sealed or unsealed.

Return type: CHARACTER
Applies to: Client-principal object handle

Syntax

```
LIST-PROPERTY-NAMES( )
```

You can also use the GET-PROPERTY( ) method to get the value of a single property associated with a Client-principal object.

The following code fragment illustrates how to use the LIST-PROPERTY-NAMES( ) method:

```
DEFINE VARIABLE hCP AS HANDLE NO-UNDO.
DEFINE VARIABLE vProp AS CHARACTER NO-UNDO.
. . .
CREATE CLIENT-PRINCIPAL hCP.
. . .
vProp = hCP:LIST-PROPERTY-NAMES( ).
DISPLAY vProp FORMAT "X(70)".
```

See also: CAN-DO function, ENTRY function, GET-PROPERTY( ) method, NUM-ENTRIES function, SET-PROPERTY( ) method

LITERAL-QUESTION attribute

Lets you specify how the AVM interprets a quoted character value during assignment into the BUFFER-VALUE attribute for a character BUFFER-FIELD object. That is, whether the AVM treats the quoted character value as a literal or non-literal character value.
When TRUE, the AVM treats a quoted character value as a literal character value. That is, it does not remove enclosing quotes, trailing blanks, or formatting insertion characters.

When FALSE, the default value, the AVM treats a quoted character value as a non-literal character value. That is, it removes enclosing quotes, trailing blanks, and formatting insertion characters. For example:

- The AVM treats "abc" as abc.
- The AVM treats a quoted question mark character ("?") as the Unknown value (?).

You can use the Literal Question (-literalquestion) startup parameter to change the default value of the LITERAL-QUESTION attribute to TRUE (which would otherwise be FALSE). For more information about this startup parameter, see OpenEdge Deployment: Startup Command and Parameter Reference.

See also: BUFFER-VALUE( ) method

LOAD( ) method (Handle)

Loads an XML document into memory, parses it, and makes its contents available in ABL as an X-document object.

This method sets the ENCODING attribute for the XML document to the encoding name specified in the XML document’s encoding declaration.

Return type: LOGICAL

Applies to: X-document object handle

Syntax

LOAD( mode, { file | memptr | longchar }, validate )

mode

A character expression that evaluates to one of the following: “FILE”, “MEMPTR”, or “LONGCHAR”.

file

A character expression that represents the name of a file that contains the source XML text. You can specify a relative pathname, an absolute pathname, or an HTTP URL. Any relative pathname is relative to the current working directory.

memptr

A MEMPTR variable that contains the source XML text. The size of the MEMPTR variable should match the size of the XML text.
**LoadControls( ) method**

*longchar*

A LONGCHAR variable that contains the source XML text. The size of the LONGCHAR variable should match the size of the XML text.

*validate*

A logical expression where TRUE indicates that the parser should validate the document’s logical structure with respect to its Document Type Definition (DTD). Note that even if validation against the DTD is not specified, the document’s physical structure is still validated. If this expression is TRUE, then the parser will also validate against any XML Schema file references in the XML document or specified in the SCHEMA-LOCATION and NONAMESPACE-SCHEMA-LOCATION attribute.

The following code fragment creates a parse tree of XML nodes and validates its structure:

```plaintext
DEFINE VARIABLE hDoc AS HANDLE NO-UNDO.
CREATE X-DOCUMENT hDoc.
   hDoc:LOAD("file", "memo.xml", TRUE).
   ...
```

**See also:** ADD-SCHEMA-LOCATION( ) method, NONAMESPACE-SCHEMA-LOCATION attribute, SCHEMA-LOCATION attribute, SCHEMA-PATH attribute

---

**LoadControls( ) method**

*(Windows only; Graphical interfaces only)*

Loads the control from a specified control file into the specified control-frame. This method loads the specified control along with all of its design-time property values.

**Return type:** None

**Applies to:** CONTROL-FRAME widget, COM object

**Syntax**

`LoadControls( control-filename , control-frame-name )`

*control-filename*

The name and extension of a control (.wrx) file associated with the current external procedure that is created by the AppBuilder at design time.

*control-frame-name*

A character-string expression that specifies the section of the control file that contains the control. Typically, this section name is also the name of the control-frame defined by the AppBuilder at design time.
References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

In a future release, this method loads multiple controls into a control-frame.

LOAD-DOMAINS( ) method

Loads registered authentication domains from the specified OpenEdge database into the application’s trusted authentication domain registry. The AVM uses this registry to validate Client-principal objects for the application during the session. After loading the registered domains, the AVM automatically restricts the registration of additional domains for the remainder of the session.

Note: Using this method to load registered authentication domains directly from an OpenEdge database provides more security than using the REGISTER-DOMAIN( ) and LOCK-REGISTRATION( ) methods because it automatically locks the registry.

Return type: LOGICAL
Applies to: SECURITY-POLICY system handle

Syntax

```
LOAD-DOMAINS( integer-expression | logical-name | alias )
```

integer-expression

The sequence number of a connected database from which to load registered domains. For example, LOAD-DOMAINS(1) loads registered domains from the first database, LOAD-DOMAINS(2) loads registered domains from the second database, and so on. If you specify a sequence number that does not correspond to a connected database, the AVM generates a run-time error.

logical-name or alias

The logical name or alias of a connected database from which to load registered domains. These forms require a quoted character string or a character expression. If you specify a logical name or alias that does not correspond to a connected database, the AVM generates a run-time error.

You can call this method only once per session.

If successful, this method returns TRUE. Otherwise, it returns FALSE.
LOAD-ICON( ) method
(Windows only; Graphical interfaces only)

Loads the icon you want from a specified file for display in the title bar of an ABL window, in the task bar, and when selecting a program using ALT+TAB. This method can accommodate icons formatted as small size (16x16) icons, regular size (32x32) icons, or both.

An icon file might contain multiple icons. In those instances when multiple icons are in a file, this method uses the 32x32 icon, if one exists, from the file that you specified. However, if a 32x32 icon does not exist, it uses the first icon in the file.

If the load is successful, this method returns TRUE.

Return type: LOGICAL
Applies to: WINDOW widget

Syntax

LOAD-ICON ( icon-filename [, n ] )

icon-filename
A character-string expression that specifies a full or relative pathname for a file that contains the icon that you want to load for display in the title bar of a window and in the task bar.

In Windows, you can specify a URL pathname for icon-filename. If you specify a fully-qualified URL, LOAD-ICON( ) loads the icon file directly without searching directories or URLs in PROPATH. Valid URL protocols include HTTP and HTTPS.

Note: URL pathnames cannot contain the percent symbol (%). If an error exists in a URL specified on the PROPATH, the LOAD-ICON( ) method continues searching with the next PROPATH entry.

If you specify URL pathnames on the PROPATH and your application repeatedly uses the LOAD-ICON( ) method with a URL pathname, you can improve performance by using the SEARCH function once to determine the full URL pathname to the directory containing the icon files. Use this value to create a fully-qualified URL pathname for icon-filename and avoid repeated searches of the PROPATH.

If you specify an empty string (""") for icon-filename, this method removes the most recently loaded icon.

n
An integer expression that specifies the position of the icon within the file. Only use this expression if you want to override the default behavior.

For example, the following invocation of LOAD-ICON( ) finds the second icon in the icon file file.ico and loads it:
The following invocation removes the previously loaded icon:

```
LOAD-ICON("").
```

You typically use this method to load a large icon, primarily for use in the ALT+TAB window for switching applications. ABL has no means of specifying a default icon for this purpose, and Windows provides a generic icon if you do not specify one.

.NET forms allow you to specify a default icon that works for this purpose using the form Icon property, which in OpenEdge is provided by the Progress.Windows.Form class. You can then change this property as required for different uses.

You can maintain uniform icons across .NET forms and ABL windows in an application by using this method to load the same large icon you are using to set the Icon property for .NET forms.

**See also:** LOAD-SMALL-ICON( ) method

---

**LOAD-IMAGE( ) method**  
(Windows only; Graphical interfaces only)

Reads the image contained in a specified file. When applied to a button widget, the image is used for the button in its up state, and also for its down state if a separate down state image is not specified. For buttons, this is equivalent to the LOAD-IMAGE-UP( ) method.

**Return type:** LOGICAL  
**Applies to:** BUTTON widget, IMAGE widget

**Syntax**

```
LOAD-IMAGE ( filename [, x-offset , y-offset , width , height ] )
```

- **filename**
  
  A character-string expression that specifies a full or relative pathname for a file that contains an image.

- **x-offset**
  
  An integer expression that specifies the pixel along the x-axis at which to begin reading from the image file.

- **y-offset**
  
  An integer expression that specifies the pixel along the y-axis at which to begin reading from the image file.
LOAD-IMAGE-DOWN( ) method

(width)

An integer expression that specifies the number of pixels along the x-axis to read from the image file.

(height)

An integer expression that specifies the number of pixels along the y-axis to read from the image file.

The image is not displayed until the widget is realized. If the read is successful, the method returns TRUE.

In Windows, you can specify a URL pathname. If you specify a fully-qualified URL, LOAD-IMAGE( ) loads the image file directly without searching directories or URLs in PROPATH. Valid URL protocols include HTTP and HTTPS.

Note: URL pathnames cannot contain the percent symbol (%). If an error exists in a URL specified on the PROPATH, the LOAD-IMAGE( ) method continues searching with the next PROPATH entry.

If you specify URL pathnames on the PROPATH and your application repeatedly uses the LOAD-IMAGE( ) method with a URL pathname, you can improve performance by using the SEARCH function once to determine the full URL pathname to the directory containing the image files. Use this value to create a fully-qualified URL pathname for filename and avoid repeated searches of the PROPATH.

LOAD-IMAGE-DOWN( ) method
(Windows only; Graphical interfaces only)

Reads the image contained in a specified file. The image is used for the button in its down state only.

Return type: LOGICAL

Applies to: BUTTON widget

Syntax

LOAD-IMAGE-DOWN( filename [ , x-offset , y-offset , width , height ] )

filename

A character-string expression that specifies a full or relative pathname for a file that contains an image to display in a button when the button is in its down state.

x-offset

An integer expression that specifies the pixel along the x-axis at which to begin reading from the image file.
**LOAD-IMAGE-INSENSITIVE() method**

**LOAD-IMAGE-INSENSITIVE( ) method**  
(Windows only; Graphical interfaces only)

Reads the image contained in the specified file. The image is used for the button in its insensitive state.

**Return type:** LOGICAL

**Applies to:** BUTTON widget

**Syntax**

```
LOAD-IMAGE-INSENSITIVE ( filename [, x-offset, y-offset, width, height ] )
```

**filename**

A character-string expression that specifies a full or relative pathname for a file that contains an image to display in a button when the button is insensitive.
**LOAD-IMAGE-UP( ) method**

**(Windows only; Graphical interfaces only)**

Reads the image contained in a specified file. The image is used for the button in its up state. The image is also used for the down state if a separate down image is not specified. This method is equivalent to the LOAD-IMAGE( ) method.

**Return type:** LOGICAL

**Applies to:** BUTTON widget

**Syntax**

```
LOAD-IMAGE-UP ( filename [ , x-offset , y-offset , width , height ] )
```
LOAD-MOUSE-POINTER( ) method

Specifies the mouse pointer to display when the pointer is moved over the widget. If you apply this method to a frame, field group, or window, the same mouse pointer is displayed when it is moved across all child widgets within the frame, field group, or window. However, if you load a different mouse pointer for a child widget, the child widget mouse pointer is displayed when it is moved over that child.

filename

A character-string expression that specifies a full or relative pathname for a file that contains an image to display in a button when the button is in its up state.

x-offset

An integer expression that specifies the pixel along the x-axis at which to begin reading from the image file.

y-offset

An integer expression that specifies the pixel along the y-axis at which to begin reading from the image file.

width

An integer expression that specifies the number of pixels along the x-axis to read from the image file.

height

An integer expression that specifies the number of pixels along the y-axis to read from the image file.

The image is not displayed until the button is realized. If the read is successful, the method returns TRUE.

In Windows, you can specify a URL pathname. If you specify a fully-qualified URL, LOAD-IMAGE-UP( ) loads the image file directly without searching directories or URLs in PROPATH. Valid URL protocols include HTTP and HTTPS.

Note: URL pathnames cannot contain the percent symbol (%). If an error exists in a URL specified on the PROPATH, the LOAD-IMAGE-UP( ) method continues searching with the next PROPATH entry.

If you specify URL pathnames on the PROPATH and your application repeatedly uses the LOAD-IMAGE-UP( ) method with a URL pathname, you can improve performance by using the SEARCH function once to determine the full URL pathname to the directory containing the image files. Use this value to create a fully-qualified URL pathname for filename and avoid repeated searches of the PROPATH.
Return type: LOGICAL
Applies to: BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

Syntax

```abel
LOAD-MOUSE-POINTER ( pointer-name )
```

**pointer-name**

A character-string expression that specifies the name of a mouse pointer.

ABL provides a collection of mouse pointers that you can use in graphical applications. Table 86 names and describes each mouse pointer in the collection.

<table>
<thead>
<tr>
<th>Pointer name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPSTARTING</td>
<td>Arrow with an hourglass beside it</td>
</tr>
<tr>
<td>ARROW</td>
<td>Standard arrow cursor</td>
</tr>
<tr>
<td>CROSS</td>
<td>Cross hairs</td>
</tr>
<tr>
<td>HELP</td>
<td>Arrow with a question mark beside it</td>
</tr>
<tr>
<td>IBEAM</td>
<td>I-beam text cursor</td>
</tr>
<tr>
<td>NO</td>
<td>Circle with a slash through it</td>
</tr>
<tr>
<td>RECTANGLE</td>
<td>(NT 3.51 only) White rectangle</td>
</tr>
<tr>
<td>SIZE</td>
<td>Sizing rectangle</td>
</tr>
<tr>
<td>SIZE-E</td>
<td>Size to right</td>
</tr>
<tr>
<td>SIZE-N</td>
<td>Size to top</td>
</tr>
<tr>
<td>SIZE-NE</td>
<td>Size to top right</td>
</tr>
</tbody>
</table>
If the mouse pointer is loaded successfully, the method returns TRUE.

In addition to the mouse pointers that ABL supplies, you can also use a bitmap that you supply that is in the form of a Windows cursor (.cur or .ani) file. To use such a bitmap, substitute the name of the Windows cursor file for \texttt{pointer-name}.

For browse columns, if you do not specify a mouse pointer, the AVM uses the mouse pointer the user specified for the browse.

In Windows, you can specify a URL pathname. If you specify a fully-qualified URL, \texttt{LOAD-MOUSE-POINTER()} loads the pointer file directly without searching directories or URLs in \texttt{PROPATH}. Valid URL protocols include HTTP and HTTPS.

\textbf{Note:} URL pathnames cannot contain the percent symbol (%). If an error exists in a URL specified on the \texttt{PROPATH}, the \texttt{LOAD-MOUSE-POINTER()} method continues searching with the next \texttt{PROPATH} entry.

If you specify URL pathnames on the \texttt{PROPATH} and your application repeatedly uses the \texttt{LOAD-MOUSE-POINTER()} method with a URL pathname, you can improve performance by using the \texttt{SEARCH} function once to determine the full URL pathname to the directory containing the pointer files. Use this value to create a fully-qualified URL pathname for \texttt{pointer-name} and avoid repeated searches of the \texttt{PROPATH}.

---

** LOAD-SMALL-ICON( ) method  
(Windows only; Graphical interfaces only)  

Loads the icon you want from a specified file for display in the title bar of a window and in the task bar only. This method can accommodate icons formatted as small size (16x16) icons, regular size (32x32) icons, or both.  

---

<table>
<thead>
<tr>
<th>Pointer name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIZE-NW</td>
<td>Size to top left</td>
</tr>
<tr>
<td>SIZE-S</td>
<td>Size to bottom</td>
</tr>
<tr>
<td>SIZE-SE</td>
<td>Size to bottom right</td>
</tr>
<tr>
<td>SIZE-SW</td>
<td>Size to bottom left</td>
</tr>
<tr>
<td>SIZE-W</td>
<td>Size to left</td>
</tr>
<tr>
<td>UPARROW</td>
<td>Up arrow</td>
</tr>
<tr>
<td>WAIT</td>
<td>System busy</td>
</tr>
<tr>
<td>GLOVE</td>
<td>Glove/finger</td>
</tr>
<tr>
<td>COMPILER-WAIT</td>
<td>Compiler busy</td>
</tr>
</tbody>
</table>
The icon file might contain multiple icons. In those instances when multiple icons are in a file, the LOAD-SMALL-ICON() method, by default, uses the 16x16 icon, if one exists, from the file that you specified. Otherwise, it uses the first icon in the file. If it uses a 32x32 icon, it reduces its size to a 16x16 format in both the title bar and the task bar.

If the load is successful, this method returns TRUE.

**Note:** You cannot use this method to display a specific icon when selecting a program using ALT+TAB.

**Return type:** LOGICAL  
**Applies to:** WINDOW widget

**Syntax**

```
LOAD-SMALL-ICON ( smallicon-filename [ n ] )
```

*smallicon-filename*

A character-string expression that specifies the name of a file that contains the icon you want to load for display in the title bar of a window and in the task bar.

In Windows, you can specify a URL pathname for *smallicon-filename*. If you specify a fully-qualified URL, LOAD-SMALL-ICON() loads the icon file directly without searching directories or URLs in PROPATH. Valid URL protocols include HTTP and HTTPS.

**Note:** URL pathnames cannot contain the percent symbol (%). If an error exists in a URL specified on the PROPATH, the LOAD-SMALL-ICON() method continues searching with the next PROPATH entry.

If you specify URL pathnames on the PROPATH and your application repeatedly uses the LOAD-SMALL-ICON() method with a URL pathname, you can improve performance by using the SEARCH function once to determine the full URL pathname to the directory containing the icon files. Use this value to create a fully-qualified URL pathname for *smallicon-filename* and avoid repeated searches of the PROPATH.

If you specify an empty string (""") for *smallicon-filename*, this method removes the most recently loaded icon.

*n*

An integer expression that specifies the position of an icon within the file. Only use this expression if you want to override the default behavior.

For example, the following invocation of LOAD-ICON() finds the second icon in the icon file *file.ico* and loads it:

```
LOAD-ICON("file.ico", 2).
```

The following invocation removes the previously loaded icon:
The LOAD-SMALL-ICON( ) method is only available in Windows 95 and NT Version 4.0. If you try to use it with any other platform, this method returns FALSE.

You typically use this method to load a small icon for an ABL window to display in its title bar or on the taskbar. ABL has no means of specifying a default icon for this purpose, and Windows provides a generic icon if you do not specify one.

.NET forms allow you to specify a default icon that works for this purpose using the form Icon property, which in ABL is provided by the Progress.Windows.Form class. You can then change this property as required for different uses.

You can maintain uniform icons across .NET forms and ABL windows in an application by using this method to load the same small icon you are using to set the Icon property for .NET forms.

See also: LOAD-ICON( ) method

---

**LOCAL-HOST attribute**

Indicates the IP (Internet Protocol) address of the machine the socket object is communicating with.

**Data type:** CHARACTER
**Access:** Readable
**Applies to:** Socket object handle

When a server and client successfully establish a connection, both the server and client have a socket object that identifies this connection. On the client and on the server, this attribute returns the IP address of the machine which is making the request. If the CONNECT method failed, this attribute returns the Unknown value (?).

---

**LOCAL-NAME attribute**

This attribute returns the unqualified part of a namespace-aware XML node name or SOAP-header-entryref element name (that is, the part after the colon character). For nodes created with the CREATE-NODE( ) method, or nodes of any type other than ELEMENT or ATTRIBUTE, this attribute returns " ".
LOCAL-PORT attribute

- **Data type:** CHARACTER
- **Access:** Readable
- ** Applies to:** SOAP-header-entryref object handle, X-noderef object handle

**LOCAL-PORT attribute**

Indicates the port number of the socket.

- **Data type:** INTEGER
- **Access:** Readable
- ** Applies to:** Socket object handle

When a server and client successfully establish a connection, both the server and client have a socket object that identifies this connection. On the client, this attribute returns the port number used on the client machine for this socket connection. On the server, this attribute returns the port number used on the server machine for this socket connection. If the CONNECT failed, this attribute returns the Unknown value (?).

**LOCATOR-COLUMN-NUMBER attribute**

The current column in the XML source.

- **Data type:** INTEGER
- **Access:** Readable
- ** Applies to:** SAX-reader object handle

Valid only in a callback. Use the SELF handle to get it, as in the following fragment:

```
myColNum = SELF:LOCATOR-COLUMN-NUMBER.
```

Gives the column number where the text that caused the current callback ends. The first column in a line is 1. If the current location is an external entity—that is, external to the main XML source—the column number is relative to the beginning of the line in the external entity.

**LOCATOR-LINE-NUMBER attribute**

The current line in the XML source.

- **Data type:** INTEGER
- **Access:** Readable
- ** Applies to:** SAX-reader object handle

Valid only in a callback. Use the SELF handle to get it, as in the following fragment:
LOCATOR-PUBLIC-ID attribute

Returns the public identifier of the current XML source.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SAX-reader object handle

Valid only in a callback. Use the SELF handle to get the public identifier of the XML source, as in the following fragment:

```
myPublicID = SELF:LOCATOR-PUBLIC-ID;
```

LOCATOR-SYSTEM-ID attribute

Returns the system identifier of the current XML source.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SAX-reader object handle

Valid only in a callback. Use the SELF handle to get the system identifier of the XML source, as in the following fragment:

```
mySystemID = SELF:LOCATOR-SYSTEM-ID;
```

LOCATOR-TYPE attribute

The type of server on which the application files are stored.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** CODEBASE-LOCATOR system handle

Valid values are "AppServer" or "InternetServer".
**LOCKED attribute**

Indicates whether another user has a lock on a record that a GET . . . WAIT statement or method is trying to access.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** Buffer object handle

**Note:** The LOCKED attribute corresponds to the LOCKED function.

**LOCK-REGISTRATION( ) method**

Restricts the registration of additional authentication domains in the application’s trusted authentication domain registry for the remainder of the session. You must call this method after you have registered all authentication domains for a session using the REGISTER-DOMAIN( ) method.

**Return type:** LOGICAL  
**Applies to:** SECURITY-POLICY system handle

**Syntax**

```plaintext
LOCK-REGISTRATION( )
```

You must call this method before you can use the trusted authentication domain registry to validate Client-principal objects for the application.

If you do not register at least one authentication domain in the trusted authentication domain registry before calling this method, this method returns TRUE. However, any attempt to seal a Client-principal object will generate a run-time error.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

**See also:** LOAD-DOMAINS( ) method, REGISTER-DOMAIN( ) method

**LOG-AUDIT-EVENT( ) method**

Creates an audit record for the specified application-defined audit event in each connected audit-enabled database whose current audit policy has this audit event enabled.

This method returns a Base64 character string that specifies a universally unique identifier (UUID) as the primary index for the generated audit event record. The UUID is 22 characters in length (the two trailing Base64 pad characters are removed).
LOG-ENTRY-TYPES attribute

**Return type:** CHARACTER

**Applies to:** AUDIT-CONTROL system handle

**Syntax**

```
LOG-AUDIT-EVENT( event-id, event-context [, event-detail [, audit-custom-detail ] ] )
```

**event-id**

An integer value that specifies an identifier for an application-defined audit event. This value must be greater than or equal to 32000.

**event-context**

A character expression that specifies the context for the audit event. The value of this expression cannot exceed 200 characters. You can also use this value as an alternate index for querying the audit event record.

If you specify the Unknown value (?), the AVM generates a run-time error.

**event-detail**

An optional character expression that specifies additional audit detail. The value of this expression cannot exceed 10,000 characters.

**audit-custom-detail**

An optional character expression that specifies additional user detail. The value of this expression cannot exceed 10,000 characters.

---

**LOG-ENTRY-TYPES attribute**

A comma-separated list of one or more types of log entries to write to the log file.

**Data type:** CHARACTER

**Access:** Readable/Writeable for LOG-MANAGER
              Readable for DSLOG-MANAGER

**Applies to:** DSLOG-MANAGER system handle, LOG-MANAGER system handle

Use the LOG-ENTRY-TYPES attribute to specify one or more types of log entries to write to the log file. For an OpenEdge client, the Client Logging (-clientlog) startup parameter or the LOG-MANAGER system handle’s LOGFILE-NAME attribute specifies the log file. For a DataServer server, the DataServer Logging (-dslog) startup parameter specifies the log file.

The LOG-ENTRY-TYPES attribute corresponds to the Log Entry Types (-logentrytypes) startup parameter.

By default, the logging level you specify using the LOGGING-LEVEL attribute or the Logging Level (-logginglevel) startup parameter applies to all log entry types specified. However, you can specify a different logging level for each entry type, as follows:
LOG-ENTRY-TYPES attribute

\[
\text{LOG-MANAGER:LOG-ENTRY-TYPES} = \log-entry-type[:\text{level}]
\]

\textit{log-entry-type}

A log entry type listed in Table 87 and Table 88.

\textit{level}

A logging level value (between 2 and 4).

Table 87 describes the log entry types for the LOG-MANAGER system handle.

Table 87: Log entry types

<table>
<thead>
<tr>
<th>Log entry type</th>
<th>Executables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4GLMessages</td>
<td>ABL (GUI and character mode). AppServer and WebSpeed do not require this log entry type for ABL messages to be written to the log file</td>
<td>Turns on logging of ABL messages. OpenEdge writes all ABL VIEW-AS ALERT-BOX messages to the log file, together with the ABL stack, when you turn on Debug Alert using either the Debug Alert (-debugalert) startup parameter or the DEBUG- ALERT attribute on the SESSION system handle.</td>
</tr>
<tr>
<td>4GLTrace</td>
<td>ABL clients, AppServer, and WebSpeed agents</td>
<td>Turns on logging for the execution of internal procedures, user-defined functions, persistent user-interface triggers, named events, and class events (generated by the RUN, FUNCTION, PUBLISH, and SUBSCRIBE statements, and (for class events) by the Publish( ), Subscribe( ), and unsubscribe( ) event methods, respectively). It also logs the instantiation and use of classes, including execution of constructors (invoked by the NEW function (classes) and also by the SUPER and THIS-OBJECT statements), the execution of methods defined within classes (including those invoked using the SUPER system reference), the execution of property accessors (invoked by accessing a property of a class), and the execution of destructors (invoked by executing the DELETE OBJECT statement or as a result of ABL garbage collection).</td>
</tr>
<tr>

Table 88 describes the log entry types for the DSLOG-MANAGER system handle.

Table 88: Log entry types (1 of 2)

<table>
<thead>
<tr>
<th>Log entry type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connects¹</td>
<td>Turns on logging for connection attributes and related information in the DataServer log file</td>
</tr>
<tr>
<td>Cursor</td>
<td>Turns on logging of cursor details in the DataServer log file</td>
</tr>
</tbody>
</table>
The following example shows how to specify one or more log entry types:

```
LOG-MANAGER:LOG-ENTRY-TYPES = "DB.Connects,4GLTrace:2,DynObjects.UI:3"
```

**Note:** If you set the LOGGING-LEVEL attribute at run time, it resets the logging level for all log entry types to the specified value. You should use LOG-ENTRY-TYPES to change logging levels for specific log entry types at run time. You must respecify all the different log entry types each time that you want to change one.

The following example shows how to specify all log entry types within a category:

```
LOG-MANAGER:LOG-ENTRY-TYPES = "DynObjects.*"
```

You can also turn off logging by setting this attribute to the Unknown value (?).

See also the reference entries for the Client Logging (-clientlog), DataServer Logging (-dslog), Log Entry Types (-logentrytypes), and Logging Level (-logginglevel) startup parameters in *OpenEdge Deployment: Startup Command and Parameter Reference*.

For more information about log entry types and logging levels, see *OpenEdge Development: Debugging and Troubleshooting*.

### LOG-THRESHOLD attribute

The file size threshold of log files. When the current log file becomes equal to or greater than the specified size, the AVM renames and saves the log file and creates a new log file.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** DSLOG-MANAGER system handle, LOG-MANAGER system handle

Valid values are:

- **0** — This means there is no limit other than what the operating system imposes. Specify 0 to ignore the Number of Log Files to Keep (-numlogfiles) startup parameter setting. This is the default.
• **Between 500,000 and 2,147,483,647** — Values are in bytes (one byte typically holds one character). You can specify a file size up to 2GB, inclusive, but not lower than 500,000.

The AVM names log files controlled by either the DSLOG-MANAGER or LOG-MANAGER system handles based on a sequence number using the following format:

```
filename.999999.extension
```

For example, if you specify a log file named `my.log`, the AVM renames the log file to `my.000001.log` before creating a new log file.

For the LOG-MANAGER system handle, the LOG-THRESHOLD attribute corresponds to the Log Threshold (`-logthreshold`) startup parameter. For the DSLOG-MANAGER system handle, this attribute corresponds to the Log Threshold (`-logthreshold`) startup parameter when the client is self-service or client/server using ProBroker. For DataServer Broker instances of the Unified Broker, the LOG-THRESHOLD attribute corresponds to the `srvrLogThreshold` attribute defined by the DataServer Broker instance in the `ubroker.properties` file.

To specify a log file name for ABL clients, use the LOG-MANAGER system handle’s `LOGFILE-NAME` attribute or the Client Logging (`-clientlog`) startup parameter. Use the LOG-MANAGER system handle’s `NUM-LOG-FILES` attribute or the Number of Log Files to Keep (`-numlogfiles`) startup parameter to specify the number of log files to keep.

For DataServers, use the DataServer Logging (`-dslog`) startup parameter to specify a log file name.

**Note:** The DSLOG-MANAGER system handle’s LOGFILE-NAME attribute is read-only.

For more information about the Client Logging (`-clientlog`), DataServer Logging (`-dslog`), Log Threshold (`-logthreshold`), and Number of Log Files to Keep (`-numlogfiles`) startup parameters, see *OpenEdge Deployment: Startup Command and Parameter Reference*, *OpenEdge Data Management: DataServer for Microsoft SQL Server*, and *OpenEdge Development: Debugging and Troubleshooting*.

**LOGFILE-NAME attribute**

The name of log file OpenEdge uses to log messages and ABL stack trace information.

**Data type:** CHARACTER

**Access:** Readable/Writeable for LOG-MANAGER

Readable for DSLOG-MANAGER

**Applies to:** DSLOG-MANAGER system handle, LOG-MANAGER system handle

If the filename you supply is a relative pathname, then a file is accessed relative to the current working directory. If the filename is an absolute pathname, then the specified file is accessed.
**Note:** Do not include a numbered sequence in the filename. This might conflict with the rolled over log files OpenEdge creates based on your NUM-LOG-FILES attribute and LOG-THRESHOLD attribute settings.

When the specified log file is open, this LOG-MANAGER attribute is read-only. This attribute is always read-only for the DSLOG-MANAGER system handle.

For the LOG-MANAGER system handle, the LOGFILE-NAME attribute corresponds to the Client Logging (-clientlog) startup parameter. For the DSLOG-MANAGER system handle, this attribute corresponds to the DataServer Logging (-dslog) startup parameter when the client is self-service or client/server using ProBroker. For DataServer Broker instances of the Unified Broker, the read-only LOGFILE-NAME attribute corresponds to the srvrDSLogFile attribute in the ubroker.properties file.

Use the LOG-ENTRY-TYPES attribute or the Log Entry Types (-logentrytypes) startup parameter to specify one or more types of log entries you want to write to the log file. Use the LOGGING-LEVEL attribute or the Logging Level (-logginglevel) startup parameter to specify a general level at which log entries are written to the log file.

For more information about the Client Logging (-clientlog), DataServer Logging (-dslog), Log Entry Types (-logentrytypes), and Logging Level (-logginglevel) startup parameters, see *OpenEdge Deployment: Startup Command and Parameter Reference*, *OpenEdge Data Management: DataServer for Microsoft SQL Server*, and *OpenEdge Development: Debugging and Troubleshooting*.

### LOGGING-LEVEL attribute

The level at which log entries are written to the log file.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** DSLOG-MANAGER system handle, LOG-MANAGER system handle

Use the LOGGING-LEVEL attribute to specify the level at which log entries are written to the log file. For an OpenEdge client, the Client Logging (-clientlog) startup parameter or the LOG-MANAGER system handle’s LOGFILE-NAME attribute specifies the log file. For a DataServer server, the DataServer Logging (-dslog) startup parameter specifies the log file. Each logging level specifies a different amount of information.

There are five logging levels:

- **0 (None)** — Log no entries. This is equivalent to turning logging off.
- **1 (Errors)** — Log ABL error messages. This includes all error messages and is unrelated to the entry types specified. Errors are logged at level 1 (Errors) and higher.
- **2 (Basic)** — Log entry type determines the logged information.
- **3 (Verbose)** — Log entry type determines the logged information.
- **4 (Extended)** — Log entry type determines the logged information.
By default, the logging level you specify applies to all log entry types. However, you can specify a different logging level for individual log entry types with the LOG-ENTRY-TYPES attribute or the Log Entry Types (-logentrytypes) startup parameter.

**Note:** If you set the LOGGING-LEVEL attribute at run time, it resets the logging level for all log entry types to the specified value. You should use LOG-ENTRY-TYPES to change logging levels for specific log entry types at run time. You must respecify all the different log entry types each time that you want to change one.

The LOGGING-LEVEL attribute corresponds to the Logging Level (-logginglevel) startup parameter.

For more information about the Client Logging (-clientlog), DataServer Logging (-dslog), Log Entry Types (-logentrytypes), or Logging Level (-logginglevel) startup parameters, see *OpenEdge Deployment: Startup Command and Parameter Reference*, *OpenEdge Data Management: DataServer for Microsoft SQL Server*, and *OpenEdge Development: Debugging and Troubleshooting*.

---

**LOGIN-EXPIRATION-TIMESTAMP attribute**

The time stamp of when the Client-principal object will expire. If the Client-principal object expires before you can seal it or validate it, the AVM sets the LOGIN-STATE attribute to “EXPIRED” and you can no longer validate or use the Client-principal object.

**Data type:** DATETIME-TZ  
**Access:** Readable/Writeable  
**Applies to:** Client-principal object handle

If not specified, the AVM will not place the Client-principal object in an EXPIRED login state and will not check the object for the EXPIRED login state condition. In this case, the AVM returns the Unknown value (?).

**Note:** The AVM recognizes that a Client-principal object has expired only when it tries to use it with the SET-CLIENT( ) method or SET-DB-CLIENT function.

Once the Client-principal object is sealed, this attribute is read-only.

**See also:** LOGIN-STATE attribute

---

**LOGIN-HOST attribute**

The name of the host system on which the user represented by the Client-principal object was authenticated. If not specified, the AVM returns a zero-length character string.
LOGIN-STATE attribute

Returns a character value that represents the current state of the Client-principal object. Valid values are: “LOGIN”, “LOGOUT”, “EXPIRED”, and “FAILED”. The default value is “LOGOUT”.

Data type: CHARACTER
Access: Readable
Applies to: Client-principal object handle

The AVM also sets the STATE-DETAIL attribute with a description of the current state.

See also: LOGIN-EXPIRATION-TIMESTAMP attribute, STATE-DETAIL attribute

LOGOUT( ) method

Indicates that the user represented by the sealed Client-principal object has logged out of the current user login session. This is a general purpose method an application can use to invalidate, or terminate access to, a sealed Client-principal object. Once logged out, you can no longer use the Client-principal object to set a user ID using either the SET-CLIENT( ) method or SET-DB-CLIENT function.

Return type: LOGICAL
Applies to: Client-principal object handle

Syntax

| LOGOUT( ) |

If you call this method for an unsealed Client-principal object, the AVM generates a run-time error. You can use the AUTHENTICATION-FAILED( ) method to invalidate an unsealed Client-principal object.

If successful, this method returns TRUE. Otherwise, it returns FALSE. The AVM also sets the LOGIN-STATE attribute for the Client-principal object to “LOGOUT”.

Calling this method generates an audit event and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.
LONGCHAR-TO-NODE-VALUE( ) method

Sets the value of an X-noderef node to the contents of a LONGCHAR.

**Return type:** LOGICAL  
**Applies to:** X-noderef object handle

**Syntax**

```
LONGCHAR-TO-NODE-VALUE( longchar )
```

`longchar`

An expression of type LONGCHAR.

LONGCHAR-TO-NODE-VALUE( ) raises an error if any of the following occurs:

- The node is read only.
- The node contains invalid XML characters.
- The data in `longchar` is not null-terminated.
- `longchar` is not set to the exact size of the valid data.

For more information on accessing XML documents using the Document Object Model (DOM) interface, see *OpenEdge Development: Working with XML*.

LOOKUP( ) method

Returns the index of the specified item in a combo-box list or selection list.

**Return type:** INTEGER  
**Applies to:** BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

**Syntax**

```
LOOKUP( list-string )
```

`list-string`

A character-string expression that specifies a single value in the combo box or selection list.

If `list-string` has the Unknown value (?), LOOKUP returns the Unknown value (?). If `list-string` is not in the list, LOOKUP returns 0.

For browses, this method applies only to combo-box browse columns.
**MANDATORY attribute**

Indicates whether a buffer-field is a required field.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Buffer-field object handle

**MANUAL-HIGHLIGHT attribute**

Indicates whether a widget exhibits custom or standard highlight behavior when selected.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

Set the MANUAL-HIGHLIGHT attribute to TRUE to use a customized highlight design for selection of the widget. A FALSE value for this attribute specifies the ABL default highlight behavior for the selection of the widget.

**MARK-NEW( ) method**

For a table with only new data, creates a blank before-table record for each buffer record, with a ROW-STATE of ROW-CREATED.

- **Return type:** LOGICAL
- **Applies to:** Buffer object handle

If a ProDataSet temp-table is known to contain only new data, MARK-NEW( ) can be used to create a before-table record for those buffer records that do not have one. ROW-STATE is set to ROW-CREATED. Using this method is easier than using MARK-ROW-STATE(ROW-CREATED), because you do not have to manually loop through all the records in the table.

MARK-NEW( ) does not support record deletes or updates.

If buffer object handle points to a static temp-table that was defined without a BEFORE-TABLE option, MARK-NEW( ) causes the AVM to raise ERROR. If buffer object handle is for a dynamic temp-table that has no before-table, one is created on-the-fly.
MARK-ROW-STATE( ) method

Forces the creation of before-table records and assigns ROW-STATE.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

If a ProDataSet contains changes to be applied to a data-source, but no BEFORE-TABLE records exist for it and therefore no ROW-STATE, you may still want to use the SAVE-ROW-CHANGES( ) method to move the new data from the ProDataSet to the source database. However, this is problematic, since SAVE-ROW-CHANGES( ) requires a before-table record with a ROW-STATE for each record to be saved. This method creates the before-table records needed by SAVE-ROW-CHANGES( ).

**Syntax**

```markdown
MARK-ROW-STATE( row-state [, before-image source buffer handle ] )
```

**row-state**

An integer expression evaluating to one of the row-state values or one of the compiler constants ROW-CREATED, ROW-MODIFIED or ROW-DELETED shown in Table 89.

**Table 89: Row state values**

<table>
<thead>
<tr>
<th>Compiler constant</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW-UNMODIFIED</td>
<td>0</td>
<td>The row was not modified.</td>
</tr>
<tr>
<td>ROW-DELETED</td>
<td>1</td>
<td>The row was deleted.</td>
</tr>
<tr>
<td>ROW-MODIFIED</td>
<td>2</td>
<td>The row was modified.</td>
</tr>
<tr>
<td>ROW-CREATED</td>
<td>3</td>
<td>The row was created.</td>
</tr>
</tbody>
</table>

**before-image source buffer handle**

An optional handle to the before-image source buffer.

If `row-state` is ROW-UNMODIFIED, or if there is already a before-table record, no action is taken.

If `row-state` is ROW-CREATED, a before-table record is created and its ROW-STATE is marked as ROW-CREATED. The before-table record is associated with the buffer object handle record.
If `row-state` is `ROW-MODIFIED` and the second optional parameter is defined, a before-image record is created by copying the before-image source buffer. If the second parameter is not defined, then a data-source must be attached to the buffer object handle. In this case the data-source mapping is used to locate the data-source record(s) related to the buffer object handle, which is used to create a before-table record. The before-table record is marked `ROW-MODIFIED` and is associated with the buffer object handle record.

**Note:** If the second parameter is not defined and if the data-source top level record cannot be located, then a `ROW-CREATED` before-table record will be created and associated with the buffer object handle record.

If `row-state` is `ROW-DELETED` and the second optional parameter is defined, a before-image record is created by copying the before-image source buffer. If the second parameter is not defined, then a data-source must be attached to buffer object handle. In this case the data-source mapping is used to locate the data-source record(s) related to buffer object handle, which then can be used to create a before-table record.

If a second parameter is not defined, then the buffer object handle must contain a temporary record whose only purpose is to locate the data-source. Otherwise it can be empty.

Note that if buffer object handle is for a static table that was defined without a `BEFORE-TABLE` option, `MARK-ROW-STATE( )` causes the AVM to raise ERROR. If buffer object handle is for a dynamic table that has no before-table, one is automatically created.

**See also:** `MARK-NEW( )` method, `ROW-STATE` attribute, `SAVE-ROW-CHANGES( )` method

---

**MAX-BUTTON attribute**  
(Windows only; Graphical interfaces only)

Determines whether the window has a maximize button in its caption bar.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** WINDOW widget

In character interfaces, this attribute has no effect.

In Windows, a window can have maximize and minimize buttons depending on the settings of the MAX-BUTTON and MIN-BUTTON attributes. Both buttons are created on the window. If you set the MAX-BUTTON to TRUE and the MIN-BUTTON to FALSE, only the maximize button is enabled; the minimize button is disabled.

The MAX-BUTTON attribute must be set before the window is realized. The default value is TRUE.
**MAX-CHARS attribute**

(Graphical interfaces only)

The maximum number of characters an editor or combo-box widget can hold.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (column), COMBO-BOX widget, EDITOR widget

For editor widgets, you can set this attribute only before the widget is realized. In Windows, the maximum value of MAX-CHARS is approximately 20K for the regular editor and over 64K for the large editor.

For SIMPLE and DROP-DOWN combo-box widgets, you can set this attribute before or after the widget is realized. If the value of MAX-CHARS for a combo-box widget is zero or the Unknown value (?), the default value is 255 characters. This attribute is ignored for DROP-DOWN-LIST combo-box widgets.

**Note:** In character interfaces, editors can grow until the AVM runs out of system resources.

For browsers, this attribute applies only to combo-box browse columns.

---

**MAX-DATA-GUESS attribute**

The estimated number of records in a browse query.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget

Before enabling the browse widget, set this attribute to the exact or maximum number of records you expect in the query. A more accurate setting of this attribute allows for a smoother and more accurate change in vertical thumb height when the user scrolls through the query for the first time. As a user scrolls through the records, the system continuously updates the value of this attribute with a better guess for the number of records. After all records have been read, the MAX-DATA-GUESS value is automatically reset to the exact number for more accurate browsing. The default value is 100.

---

**MAX-HEIGHT-CHARS attribute**

The maximum height of the window, in character units.
**MAX-HEIGHT-PIXELS attribute**

The maximum height of the window, in pixels.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** WINDOW widget

**MAXIMUM-LEVEL attribute**

Forces a recursive data-relation to stop at a specific number of iterations of a child buffer. This attribute causes a recursive ProDataSet FILL to stop when the number of iterations of the child buffer reaches the MAXIMUM-LEVEL.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** Data-relation object handle  
**See also:** DEFINE DATASET statement, GET-RELATION( ) method, RECURSIVE attribute

**MAX-VALUE attribute**

The maximum value for a slider.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** SLIDER widget  
You can set this attribute only before the widget is realized.

**MAX-WIDTH-CHARS attribute**

The maximum width of a window, in character units.
MAX-WIDTH-PIXELS attribute

Data type: DECIMAL
Access: Readable/Writeable
Applies to: WINDOW widget

MAX-WIDTH-PIXELS attribute

The maximum width of a window, in pixels.

Data type: INTEGER
Access: Readable/Writeable
Applies to: WINDOW widget

MD5-VALUE attribute

Returns the MD5 value stored in an r-code file.

Data type: CHARACTER
Access: Readable
Applies to: RCODE-INFO system handle

The return value is a 32 character hexadecimal number.

Use this attribute to determine if a procedure changed between different versions of your application.

If you did not use the GENERATE-MD5 option on the COMPILE statement to compile a procedure or class, the AVM did not store the MD5 value in the r-code file. In this case, this attribute returns the Unknown value (?).

MEMPTR-TO-NODE-VALUE( ) method

Sets the value of an X-noderef node to the contents of a MEMPTR.

Return type: LOGICAL
Applies to: X-noderef object handle

Syntax

\[
\text{MEMPTR-TO-NODE-VALUE( memptr )}
\]

memptr

An expression of type MEMPTR.

MEMPTR-TO-NODE-VALUE( ) raises an error if any of the following occurs:

- The node is read only.
The node contains invalid XML characters.

The data in memptr is not null-terminated.

memptr is not set to the exact size of the valid data.

For more information on accessing XML documents using the Document Object Model (DOM) interface, see OpenEdge Development: Working with XML.

### MENU-BAR attribute

The handle of a menu bar widget associated with a window.

**Data type:** HANDLE

**Access:** Readable/Writeable

**Applies to:** WINDOW widget

You can establish the menu bar for a window by assigning the MENU-BAR attribute.

### MENU-KEY attribute

The accelerator key sequence that activates the pop-up menu for a widget.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

Any value you set must evaluate to a valid ABL key label, such as "a", "F1", or "ALT-SHIFT-F1".

### MENU-MOUSE attribute

(Graphical interfaces only)

The mouse button on a three-button mouse that activates the pop-up menu for a widget.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

Table 90 lists each mouse button and the attribute value that specifies it as the pop-up menu button.
If you use a two-button mouse, setting this attribute to "2" makes it impossible to access the menu with your mouse. If you do not set this attribute, it returns the Unknown value (?).

**MERGE-BY-FIELD attribute**

Specifies whether the AVM merges changes on a field-by-field basis when saving changes from a ProDataSet temp-table buffer to the associated data source using the SAVE-ROW-CHANGES( ) method. The default value is TRUE.

<table>
<thead>
<tr>
<th>Note:</th>
<th>Merging a large number of changes from a ProDataSet object to the data source on a field-by-field basis is slower than saving changes buffer-by-buffer.</th>
</tr>
</thead>
</table>

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Data-source object handle

If TRUE, the AVM performs a field-to-field comparison to identify data conflicts. In this case, a data conflict exists when the same field in the ProDataSet buffer and its associated data source buffer has changed. A data conflict would not exist if a different field had changed in either buffer.

If FALSE, the AVM performs a buffer-to-buffer comparison to identify data conflicts. In this case, a data conflict exists when any field in the data source buffer has changed.

**MERGE-CHANGES( ) method**

Merges the changed rows from a ProDataSet object loaded with the GET-CHANGES( ) method into the corresponding rows in either a single temp-table or all temp-tables in the original ProDataSet object.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle, ProDataSet object handle

**Syntax**

\[
\text{change-handle:MERGE-CHANGES( original-handle [, copy-all-mode ] )}
\]
change-handle
A handle to the ProDataSet object or ProDataSet temp-table buffer that contains the changed rows.

original-handle
A handle to the original ProDataSet object or ProDataSet temp-table buffer to merge with the changed rows.

copy-all-mode
An optional logical expression where TRUE indicates that the AVM merge rows in a copy-all mode. When TRUE, the AVM merges all after-image table rows whether or not they contain changes. In this case, the temp-table in the original ProDataSet object must have a unique primary index that the AVM can use to find each corresponding row from the after-image table (since unchanged rows do not have a corresponding row in the before-image table). When a corresponding row is not found in the original ProDataSet object, the AVM creates a new row using the row from the after-image table. When FALSE, the AVM merges only after-image table rows that contain changes. The default value is FALSE.

For a ProDataSet object handle, all modified tables in the ProDataSet object are merged. For a Buffer object handle, only the temp-table associated with that buffer is merged.

If the ERROR attribute or REJECTED attribute for a changed table is TRUE, the MERGE-CHANGES( ) method backs out the changes. Otherwise, this method accepts the changes by copying the after-image table rows to the corresponding after-image table rows in the original ProDataSet temp-table. The AVM also sets the BEFORE-ROWID attribute of the row in the after-image table to the Unknown value (?), sets the ROW-STATE of the row in the after-image table to ROW-UNMODIFIED (0), and removes the before-image table row (if it has one).

MERGE-ROW-CHANGES( ) method
Merges a single changed row from a ProDataSet object loaded with the GET-CHANGES( ) method into the corresponding row in the original ProDataSet temp-table buffer.

Return type: LOGICAL
Applies to: Buffer object handle

Syntax

```
change-handle:MERGE-ROW-CHANGES([original-handle[,copy-all-mode]])
```

change-handle
A handle to the ProDataSet before-image temp-table buffer for a changed row, or an after-image temp-table buffer for an unchanged row.

original-handle
A handle to the original ProDataSet temp-table buffer to merge with the changed row.
The AVM uses \textit{original-handle} only to match to the original table currently associated with \textit{change-handle} (specified in the ORIGIN-HANDLE attribute). The current row in this table is ignored.

\textit{copy-all-mode}

An optional logical expression where TRUE indicates that the AVM merge the row in a \textit{copy-all} mode. When TRUE, the AVM merges the after-image table row whether or not it contains changes. In this case, the temp-table in the original ProDataSet object must have a unique primary index that the AVM can use to find each corresponding row from the after-image table (since an unchanged row does not have a corresponding row in the before-image table). When a corresponding row is not found in the original ProDataSet object, the AVM creates a new row using the row from the after-image table. When FALSE, the AVM merges only an after-image table row that contain changes. The default value is FALSE.

If the ERROR attribute or REJECTED attribute for the changed row is TRUE, the MERGE-ROW-CHANGES( ) method backs out the change. Otherwise, this method accepts the change by copying the after-image table row to the corresponding after-image table row in the original ProDataSet temp-table. The AVM also sets the BEFORE-ROWID attribute of the row in the after-image table to the Unknown value (\textit{?}), sets the ROW-STATE of the row in the after-image table to ROW-UNMODIFIED (0), and removes the before-image table row (if it has one).

\textbf{Note:} The after-image table row, that contains the changes to the corresponding after-image table row in the original ProDataSet temp-table, contains changes from the original ProDataSet temp-table as well as any changes made in the associated data source row based on the MERGE-BY-FIELD attribute and PREFER-DATASET attribute settings in effect during the save operation.

\section*{MESSAGE-AREA attribute (Graphical interfaces only)}

Controls the appearance of the message area in the window.

\begin{description}
\item[Data type:] LOGICAL
\item[Access:] Readable/Writeable
\item[Applies to:] WINDOW widget
\end{description}

You can set this attribute only before the window is realized.

\section*{MESSAGE-AREA-FONT attribute}

The font number of the font used in the message area of a window.
### MIN-BUTTON attribute

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** WINDOW widget

The font number represents an entry in the font table maintained by the FONT-TABLE handle.

---

**MIN-BUTTON attribute**  
**(Windows only; Graphical interfaces only)**

Determines whether the window has a minimize button in its caption bar.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** WINDOW widget

In Windows, a window can have maximize and minimize buttons depending on the settings of the MIN-BUTTON and MAX-BUTTON attributes. Both buttons are created on the window. If you set the MIN-BUTTON to TRUE and the MAX-BUTTON to FALSE, only the MIN-BUTTON is enabled; the MAX-BUTTON is disabled.

The MIN-BUTTON attribute must be set before the window is realized. The default value is TRUE.

On character platforms, this attribute has no effect.

---

**MIN-COLUMN-WIDTH-CHARS attribute**  
**(Graphical interfaces only)**

Sets the minimum width of a browse column in character units. If the browse has not been realized, all browse columns are minimally this size when realized. If the browse has been realized, any browse column smaller than the specified minimum is increased to the minimum width.

**Data type:** Decimal  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget

The default value for the MIN-COLUMNS-WIDTH-CHARS attribute is equivalent to 1 pixel and depends on the display resolution and the size of the default font of the system.

An error occurs if you attempt to programmatically set the width of a browse column to a value smaller than the value specified with the MIN-COLUMN-WIDTH-CHARS attribute.

If COLUMN-RESIZABLE is set to TRUE, the user cannot change a column’s width to be less than the minimum width specified with the MIN-COLUMN-WIDTH-CHARS attribute.
The MIN-COLUMN-WIDTH-CHARS attribute affects the FIT-LAST-COLUMN attribute. Therefore, if you set FIT-LAST-COLUMN to TRUE, the last browse column is only resized to fit within the viewport if its width is no smaller than the minimum width. See the FIT-LAST-COLUMN attribute for more information about the FIT-LAST-COLUMN attribute.

When you assign a decimal value to an attribute representing a measurement in character units, the AVM automatically rounds the assigned value to the nearest decimal value that corresponds to whole pixel units.

**MIN-COLUMN-WIDTH-PIXELS attribute**  
*(Graphical interfaces only)*

Sets the minimum width of a browse column in pixels. If the browse has not been realized, all browse columns are minimally this size when realized. If the browse has been realized, any browse column smaller than the specified minimum is increased to the minimum width.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget

The default minimum browse column width is 1 pixel.

An error occurs if you attempt to programmatically set the width of a browse column to a value smaller than the value specified using the MIN-COLUMN-WIDTH-PIXELS attribute.

If COLUMN-RESIZABLE is set to TRUE, the user cannot change a column’s width to be less than the minimum width specified with the MIN-COLUMN-WIDTH-PIXELS attribute.

The MIN-COLUMN-WIDTH-PIXELS attribute affects the FIT-LAST-COLUMN attribute. As a result, if FIT-LAST-COLUMN is set to TRUE, the last browse column is only resized to fit within the viewport if its width is no smaller than the minimum width. See the FIT-LAST-COLUMN attribute for more information about the FIT-LAST-COLUMN.

**MIN-HEIGHT-CHARS attribute**

The minimum height of a window, in character units.

- **Data type:** DECIMAL
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget, WINDOW widget

**MIN-HEIGHT-PIXELS attribute**

The minimum height of a window, in pixels.
MIN-SCHEMA-MARSHAL attribute

Set to TRUE to minimize schema information when marshaling data for a temp-table parameter. The temp-table may be an independent temp-table or a member of a ProDataSet object.

This attribute is supported only for backward compatibility. Use the SCHEMA-MARSHAL attribute instead.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: Temp-table object handle

This attribute suppresses index descriptions and some field information (such as label, help, field validation expression, and so on) when marshaling data. It does marshal field names, data types, and extents.

The MIN-SCHEMA-MARSHAL attribute corresponds to the SCHEMA-MARSHAL attribute with a value of "MIN".

Note: If you specify both the MIN-SCHEMA-MARSHAL attribute and the SCHEMA-MARSHAL or NO-SCHEMA-MARSHAL attribute for an individual temp-table, the AVM uses the attribute you most recently specified.

Setting this attribute overrides the setting of the Temp-table Schema Marshal (-ttmarshal) startup parameter for an individual temp-table parameter. For more information about this startup parameter, see OpenEdge Deployment: Startup Command and Parameter Reference.

See also: NO-SCHEMA-MARSHAL attribute, SCHEMA-MARSHAL attribute

MIN-VALUE attribute

The minimum value of a slider.

Data type: INTEGER
Access: Readable/Writeable
Applies to: SLIDER widget

You can set this attribute only before the widget is realized.

MIN-WIDTH-CHARS attribute

The minimum width of a window, in character units.
**MIN-WIDTH-PIXELS attribute**

Data type: DECIMAL
Access: Readable/Writeable
Applies to: WINDOW widget

The minimum width of a window, in pixels.

**MIN-WIDTH-PIXELS attribute**

Data type: INTEGER
Access: Readable/Writeable
Applies to: WINDOW widget

**MODIFIED attribute**

Indicates whether the value of the SCREEN-VALUE attribute for the widget has changed.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BROWSE widget (browse and column), COMBO-BOX widget, EDITOR widget, FILL-IN widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

For browse columns, this attribute is readable only.

For all widgets, the MODIFIED attribute is set to TRUE when the SCREEN-VALUE attribute for the widget is changed, whether or not the field is enabled. For all widgets except the editor widget, the MODIFIED attribute is set to TRUE if the SCREEN-VALUE attribute for the widget is changed using an ABL statement, such as assignment or DISPLAY. DISPLAY sets MODIFIED to TRUE only when the field is enabled. You can then reset the attribute to FALSE for each widget that can receive input focus or otherwise change value after it is initially displayed.

For editors, the successful execution of either the SAVE-FILE( ) or the READ-FILE( ) methods sets the MODIFIED attribute to FALSE.

For browses, if any browse cell changes, the AVM sets MODIFIED to TRUE. The application can reset MODIFIED to FALSE as necessary. If the query associated with a browse is reopened, the AVM resets MODIFIED to FALSE.

If the widget is not already realized and you reference its MODIFIED attribute, the AVM realizes the widget.

You can use the SENSITIVE attribute to reset the MODIFIED attribute. For example, when the screen-value of a fill-in field is changed, MODIFIED is set to TRUE. If you then set SENSITIVE to FALSE and then to TRUE, you enable the fill-in for further input and the MODIFIED attribute is reset to FALSE.
MOUSE-POINTER attribute

Returns the name of the mouse pointer loaded by LOAD-MOUSE-POINTER( ).

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

MOVABLE attribute
(Graphical interfaces only)

Indicates whether the widget can receive direct manipulation events.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

Set MOVABLE to TRUE to enable users to move the widget. To enable users to move more than one widget at a time, you must also set the SELECTABLE attribute to TRUE for each widget.

**Note:** Setting the MOVABLE attribute to TRUE enables direct manipulation events for the widget. These events take precedence over all other events. This effectively prevents data entry using the widget until all direct manipulation events are disabled (that is, until MOVABLE, RESIZABLE, and SELECTABLE are all FALSE).

MOVE-AFTER-TAB-ITEM( ) method

Assigns the method widget to the tab position after a specified widget. Both the method widget and the specified widget must be in the same field group.

**Return type:** LOGICAL

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

**Syntax**

MOVE-AFTER [ -TAB-ITEM ] ( handle )
MOVE-BEFORE-TAB-ITEM( ) method

handle

A handle to the widget after whose tab position you want to move the method widget.

If the operation is successful, the method returns TRUE. To set the first or last tab position, set the FIRST-TAB-ITEM or LAST-TAB-ITEM attribute (respectively) for the field group.

If handle specifies a frame, the tab order of the method widget is positioned so that it follows the last widget parented by the frame in that frame's own tab order. For more information on how frames owned by a field group participate in the tab order of that field group, see the FRAME widget reference entry.

Note: Any tab reordering that you do with this method can be reset by a subsequent ENABLE statement unless you define the frame that owns the field group with the KEEP-TAB-ORDER option. For more information, see the ENABLE statement and Frame phrase reference entries.

MOVE-BEFORE-TAB-ITEM( ) method

Assigns the method widget to the tab position before a specified widget. Both the method widget and the specified widget must be in the same field group.

Return type: LOGICAL

Applies to: BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

Syntax

MOVE-BEFORE [ -TAB-ITEM ] ( handle )

handle

A handle to the widget before whose tab position you want to move the method widget.

If the operation is successful, the method returns TRUE. To set the first or last tab position, set the FIRST-TAB-ITEM or LAST-TAB-ITEM attribute (respectively) for the field group.

If handle specifies a frame, the tab order of the method widget is positioned so that it precedes the first widget parented by the frame in that frame's own tab order. For more information on how frames owned by a field group participate in the tab order of that field group, see the FRAME widget reference entry.

Note: Any tab reordering that you do with this method can be reset by a subsequent ENABLE statement unless you define the frame that owns the field group with the KEEP-TAB-ORDER option. For more information, see the ENABLE statement and Frame phrase reference entries.
MOVE-COLUMN( ) method
(Graphical interfaces only)

Repositions a column in a browse widget.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
MOVE-COLUMN ( source , destination )
```

*source*

An integer expression specifying the column to be moved.

*destination*

An integer expression specifying the position to which the column is moved.

The columns of a browse are numbered left to right beginning with 1 including both visible and hidden columns. For example, `browse:MOVE-COLUMN(1, 3)` moves the first column to the third position (the second column becomes the first column and the third column becomes the second column). If the column is successfully moved, the method returns the value TRUE.

MOVE-TO-BOTTOM( ) method

Moves the widget to the bottom (or back) of other widgets of the same class on the display.

**Return type:** LOGICAL

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

**Syntax**

```
MOVE-TO-BOTTOM ( )
```

For the purposes of this method, the classes are as follows:

- Windows
- Frames
- Images and rectangles
- All other field-level widgets

If the operation is successful, the method returns TRUE.

When you use this method, set the KEEP-FRAME-Z-ORDER attribute to TRUE.
MOVE-TO-EOF( ) method

Moves the cursor position in an editor to the end of the current text.

**Return type:** LOGICAL  
**Applies to:** EDITOR widget

**Syntax**

```
MOVE-TO-EOF ( )
```

If the operation is successful, the method returns TRUE.

MOVE-TO-TOP( ) method

Moves the widget to the top (or front) of other widgets of the same class on the display.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

**Syntax**

```
MOVE-TO-TOP ( )
```

For the purposes of this method, the classes are as follows:

- Windows
- Frames
- Images and rectangles
- All other field-level widgets

If the operation is successful, the method returns TRUE.

Images and rectangles are displayed behind other field-level widgets and cannot be moved on top of them.

When you use this method, set the KEEP-FRAME-Z-ORDER attribute to TRUE.

**Note:** In character interfaces, the MOVE-TO-TOP method applies only to the Frame.
**MULTI-COMPILE attribute**

Specifies whether ABL compiles all class definition files in the inherited class hierarchy or only those class definition files for which a cached version is not found.

**Note:** This attribute is applicable only when compiling class definition (.cls) files.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** COMPILER system handle

When set to TRUE, ABL compiles only those class definition files in the inherited class hierarchy that are not found in the cache. ABL also caches any classes or interfaces it compiles to avoid recompiling them during the session.

When set to FALSE, ABL compiles all class definition files in the inherited class hierarchy. ABL also clears the cache of any classes or interfaces compiled during the session. The default value is FALSE.

**MULTIPLE attribute**

Indicates the selection behavior of browse selection list widgets, and the read and write behavior of the system clipboard.

**Data type:** LOGICAL  
**Access:** Readable/Writeable (Read-only for browse)  
**Applies to:** BROWSE widget, CLIPBOARD system handle, SELECTION-LIST widget

For browse widgets, the MULTIPLE attribute specifies whether the user can select multiple rows from the widget, or only a single row. (Typically, the selected rows are processed in response to a DEFAULT-ACTION event.) The MULTIPLE attribute is read-only for browse widgets. The MULTIPLE attribute for a browse can be set before the browse is realized. Use the MULTIPLE or SINGLE option of the browse phrase in the DEFINE BROWSE statement to set the selection behavior for a browse widget. The MOUSE-SELECT-DOWN and MOUSE-SELECT-UP events are generated as the user scrolls through the browse.

**Note:** When an updateable browse is in edit mode, a cell has focus, all other selected rows are deselected.

For selection-list widgets, the MULTIPLE attribute specifies whether the user can select multiple items from the widget, or only a single item. (Typically, the selected rows are processed in response to a DEFAULT-ACTION event.) You can specify selection behavior for a selection list using the MULTIPLE or SINGLE option of a SELECTION-LIST phrase. You can set this attribute for a selection list only before the widget is realized.
MULTITASKING-INTERVAL attribute

(Windows only)

How often the AVM filters events between itself and other Windows applications.

Data type: INTEGER
Access: Readable/Writeable
Applies to: SESSION system handle

The value of the MULTITASKING-INTERVAL attribute determines how often the AVM internally filters events (messages) between itself and other Windows applications. As the AVM filters these events more often, it executes procedures less efficiently, but allows other windows applications more opportunity to execute. Adjusting the internal event filter is particularly useful during background processing, such as report generation.

The default value, zero, tells the AVM never to filter events internally, giving ABL applications maximum access to execution resources. This is perfectly adequate for interactive ABL applications that block for input often, giving other applications enough opportunity to execute.

For values greater than zero, the lower the value, the more often the AVM internally filters events, giving other applications greater opportunity to execute, but slowing down the AVM execution. However, similar to a TRUE value for the IMMEDIATE-DISPLAY attribute, low non-zero values also cause the AVM to refresh the display more often, potentially providing crisper display interaction. Low non-zero values also provide better interoperability with other applications, for example, using Dynamic Data Exchange (DDE).

The maximum value you can set is 9999. In general, set this attribute greater than zero only for code segments that perform lengthy background operations, and reset it to zero before the application blocks for interactive input (for example, executes a WAIT-FOR or UPDATE statement). This attribute provides the same functionality as the MultitaskingInterval parameter in the current environment, which might be the Registry (Windows only) or an initialization file. For more information on environments, see the chapter on user interface environments in OpenEdge Deployment: Managing ABL Applications.

MUST-UNDERSTAND attribute

Indicates whether a SOAP-header-entryref object is mandatory (TRUE) or optional (FALSE) for the recipient to process.
Name property

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** SOAP-header-entryref object handle

If the SOAP-header-entryref object does not contain a MUST-UNDERSTAND attribute, this attribute returns FALSE.

---

Name property
(Windows only; Graphical interfaces only)

The name of the control-frame and control-frame COM object.

**Return type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** CONTROL-FRAME widget, COM object

Setting this value changes the NAME attribute of the corresponding control-frame widget to the same value.

---

**Note:** References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

---

**Caution:** If you change the value of this property at run time, any OCX event procedures that you have defined for a corresponding ActiveX control will not respond to control events because the events are sent with the new name.

---

NAME attribute

A string identifier for the specified object or widget.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** Asynchronous request object handle, BROWSE widget (browse, column, and cell), Buffer object handle, Buffer-field object handle, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, Data-relation object handle, Data-source object handle, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU widget, MENU-ITEM widget, Procedure object handle, ProDataSet object handle, Query object handle, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, Server object handle, Server socket object handle, SLIDER widget, SOAP-header object handle, SOAP-header-entryref object handle, Socket object handle, SOURCE-PROCEDURE system handle, Stream object handle, SUB-MENU widget, TARGET-PROCEDURE system handle, Temp-table object handle,
NAME attribute

**TEXT widget, THIS-PROCEDURE system handle, TOGGLE-BOX widget, WINDOW widget, X-document object handle, X-noderef object handle**

For the SOAP-header and SOAP-header-entryref object handles, this attribute is read-only.

For static data representation widgets, the default value is the name of the field or variable associated with the widget. You can use the NAME attribute to store any information associated with the widget.

For a state-reset, state-aware, or stateless AppServer, this attribute returns the connection ID for the AppServer associated with the server handle. For a state-free AppServer, it returns the connection ID of the first AppServer connection created in the session pool with this server handle when the application service is first bound using the CONNECT( ) method. The default value is the unique connection name of the AppServer.

For Web services, the default value is the URL of the Web service procedure object from the WSDL. This is the portType name used on the RUN statement that instantiated this object.

For a non-Web service procedure, returns the pathname of the procedure file that contains the current procedure.

For control-frames, this attribute maps to the Name property of the of the control-frame COM object (ActiveX control container).

For dynamic widgets and asynchronous request handles, this attribute defaults to the Unknown value (?).

**Caution:** If you change the value of this property at run time, any OCX event procedures that you have defined for a corresponding ActiveX control will not respond to control events because the events are sent with the new name.

For query objects, the NAME attribute applies only to static queries.

For the SOAP-header object handle, this attribute is the qualified name of the SOAP-header object, which consists of a namespace prefix + “:” + HEADER.

For the SOAP-header-entryref object handle, this attribute is the qualified name of the SOAP-header-entryref object, which consists of a namespace prefix + “:” + localname. You cannot change this attribute directly; you must use the local-name and namespace-prefix.

The NAME attribute of the Temp-table object handle is writeable for dynamic and AVM-generated temp-tables. A new temp-table name cannot be assigned until after the TEMP-TABLE-PREPARE() method has been executed.

For the X-document object handle or X-noderef object handle, this attribute returns the name of the XML node.

For any object or widget, this attribute can contain any arbitrary value that you set.
NAMESPACE-PREFIX attribute

This attribute returns or sets the qualified part of a namespace-aware XML node name (that is, the prefix before the colon character). The prefix is used to identify elements that belong to the namespace associated with the prefix (as set by the NAMESPACE-URI attribute). For nodes created with the CREATE-NODE( ) method, or nodes of any type other than ELEMENT or ATTRIBUTE, this attribute returns the Unknown value (?).

Data type: CHARACTER  
Access: Readable/Writeable  
Applies to: Buffer object handle, ProDataSet object handle, Temp-table object handle, X-document object handle, X-noderef object handle

This attribute is read-only for the X-document object handle.

NAMESPACE-URI attribute

The namespace URI of a namespace-aware XML node name, a SOAP-header-entryref object, or a ProDataSet or Temp-Table element and its child elements. The namespace of an XML document is used to scope XML attributes and elements. For nodes created with the CREATE-NODE( ) method, or nodes of any type other than ELEMENT or ATTRIBUTE, this attribute returns the Unknown value (?).

Data type: CHARACTER  
Access: Readable/Writeable  
Applies to: Buffer object handle, ProDataSet object handle, SOAP-header-entryref object handle, Temp-table object handle, X-document object handle, X-noderef object handle

This attribute is read-only for the SOAP-header-entryref object handle, X-document object handle, and X-noderef object handle.

NEEDS-APPSERVER-PROMPT attribute

Indicates whether WebClient should prompt for AppServer connection parameters, if it does not find those values in the security cache, (TRUE) or not (FALSE).

Data type: LOGICAL  
Access: Readable  
Applies to: CODEBASE-LOCATOR system handle

Valid only if LOCATOR-TYPE is "AppServer".
**NEEDS-PROMPT attribute**

Indicates whether WebClient should prompt for an Internet server userid and password, if it does not find those values in the security cache, (TRUE) or not (FALSE).

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** CODEBASE-LOCATOR system handle

**NESTED attribute**

Indicates whether child rows of a ProDataSet temp-table buffer are nested within their parent rows when writing the XML representation of a ProDataSet object that contains data-relations. This also causes the XML Schema definitions for the related temp-tables to be nested.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** Data-relation object handle
- **See also:** ADD-RELATION( ) method, DEFINE DATASET statement, WRITE-XML( ) method, WRITE-XMLSCHEMA( ) method

**NEW attribute**

Indicates whether the record in the buffer is newly created. If the record is newly created, NEW is TRUE. If the record in the buffer was read from the database, NEW is FALSE.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Buffer object handle

**Note:** The NEW attribute corresponds to the NEW function.

**NEW-ROW attribute**

Indicates whether the focused browse row exists in the database.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** BROWSE widget

If this attribute is set to TRUE, the row in focus was added to the browse using the INSERT-ROW( ) method and has not been added to the database.
**NEXT-COLUMN attribute**

The handle of the next sibling, in physical order, of the current browse column whether or not the column is visible. The browse MOVE-COLUMN method changes the physical order of columns and updates this attribute accordingly.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:** BROWSE widget (column)

**NEXT-ROWID attribute**

Provides the ROWID of the data source row at which the next FILL operation should start. The AVM sets this attribute after each FILL operation in a series of FILL operations to retrieve data source rows in batches. You typically assign the value of this attribute to the RESTART-ROWID attribute before each FILL operation.

- **Note:** This attribute is not marshalled between the client and the AppServer. You are responsible for retrieving, storing, and transporting this attribute value between the client and the AppServer.

- **Data type:** ROWID
- **Access:** Readable/Writeable
- **Applies to:** Data-source object handle

**Syntax**

```
data-source-handle:NEXT-ROWID( buffer-sequence-number | buffer-name )
```

- `data-source-handle` The handle to the Data-source object.

- `buffer-sequence-number` An integer that represents the sequence number of a buffer in the list of buffers for the Data-source object. Specify `buffer-sequence-number` to identify a buffer in the Data-source object when the Data-source object is defined against more than one database table buffer. The default is the first (or only) buffer in the Data-source object.

- **Note:** Sequence numbers for buffers in a Data-source object start at one, where one represents the top level and subsequent numbers represent lower levels of join, if any.

- `buffer-name` A CHARACTER expression that evaluates to the name of a buffer in the list of buffers for the Data-source object.

If an invalid buffer is specified, this attribute returns the Unknown value (?).
It is best to use the NEXT-ROWID attribute with a top-level ProDataSet temp-table, or a child temp-table that has only one parent record, because the AVM sets this attribute on the child temp-table for each parent record (as opposed to once per child temp-table).

Use this attribute when retrieving batches of data source rows containing stable data. Otherwise, it might be better to use a unique index to reopen the query associated with the Data-source object to retrieve a specific batch of data source rows.

See also: BATCH-SIZE attribute, FILL( ) method, RESTART-ROWID attribute

**NEXT-SIBLING attribute**

The next entry in a list of handles, relative to a given handle.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:**
  - Asynchronous request object handle, BROWSE widget, Buffer object handle, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, Data-source object handle, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU-ITEM widget, Procedure object handle, ProDataSet object handle, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, Server object handle, SLIDER widget, Socket object handle, Server socket object handle, SESSION system handle, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

Table 91 summarizes the value of NEXT-SIBLING for each relevant handle type.

<table>
<thead>
<tr>
<th>Handle type</th>
<th>Value of NEXT-SIBLING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asynchronous Request</td>
<td>The handle of the next asynchronous request submitted for execution on the AppServer or Web Server that is running the specified request.</td>
</tr>
<tr>
<td>Procedure</td>
<td>The handle of the next persistent procedure in the current ABL session. If the current procedure is a proxy for a persistent procedure running on an AppServer or for a Web service, specifies the next procedure object bound to the same server handle.</td>
</tr>
<tr>
<td>Server</td>
<td>The next server handle created in the current ABL session (independent of subtype).</td>
</tr>
<tr>
<td>Socket and Server-socket</td>
<td>The next socket handle in the chain of socket handles for the current ABL session. Returns the Unknown value (?) for the last handle in the chain.</td>
</tr>
</tbody>
</table>
The NEXT-TAB-ITEM attribute returns the Unknown value (?) for a widget that is at the end of the tab order in a field group.

**Table 91: NEXT-SIBLING attribute values by handle type**

<table>
<thead>
<tr>
<th>Handle type</th>
<th>Value of NEXT-SIBLING</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProDataSet object</td>
<td>The handle to the next dynamic ProDataSet object in the chain of ProDataSet objects for the current ABL session, which is available after using the SESSION:FIRST-DATASET attribute.</td>
</tr>
<tr>
<td>Dynamic query</td>
<td>The handle to the next dynamic query in the chain of dynamic queries for the current ABL session, which is available after using the SESSION:FIRST-QUERY attribute.</td>
</tr>
<tr>
<td>Dynamic Data-source object</td>
<td>The handle to the next dynamic Data-source object in the chain of dynamic Data-source objects for the current ABL session, which is available after using the SESSION:FIRST-DATA-SOURCE attribute.</td>
</tr>
<tr>
<td>Buffer object</td>
<td>The handle to the next buffer object in the session buffer list, which is available after using the SESSION:FIRST-BUFFER attribute.</td>
</tr>
<tr>
<td>Widget</td>
<td>The handle of the next widget in the widget list.</td>
</tr>
</tbody>
</table>

Note: A widget must first be realized before it can become part of the list. A hidden widget cannot become part of the list since it is not realized. A widget that is already part of the list can be hidden and it remains part of the list.

If the given handle is the last handle in the list, NEXT-SIBLING assumes the value of an invalid handle. To check the validity of a handle, use the VALID-HANDLE function.

See also: PREV-SIBLING attribute

**NEXT-TAB-ITEM attribute**

The handle of the next widget in the tab order of a field group relative to the specified widget.

**Data type:** HANDLE  

**Access:** Readable  

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

The NEXT-TAB-ITEM attribute returns the Unknown value (?) for a widget that is at the end of the tab order in a field group.

**NO-CURRENT-VALUE attribute**

The default behavior for a slider is to display the current value for a given position on a slider control. The NO-CURRENT-VALUE attribute allows you to override this default behavior.
NO-EMPTY-SPACE attribute

**LOGICAL**

**Readable/Writeable**

**SLIDER widget**

(NO-EMPTY-SPACE attribute
( Graphical interface only )

Allows the browse to display with no empty space to the right and no horizontal scroll bar.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget

When the last browse column can be fully displayed in the browse viewport with empty space to the right, you can use NO-EMPTY-SPACE attribute to widen the width of the last browse column so that the column fits within the viewport with no empty space to its right and no horizontal scroll bar.

The default value is FALSE.

The following shows the DEFINE BROWSE statement syntax with NO-EMPTY-SPACE specified:

```
DEFINE BROWSE b1 QUERY q1
   DISPLAY Customer.CustNum Customer.Name
   ENABLE Customer.CustNum WITH 3 DOWN WIDTH 40 NO-EMPTY-SPACE
```

NO-EMPTY-SPACE is primarily intended for use in the initial layout of a static browse. It is most useful when laying out a browse with a specified width when you have only a few browse columns, and you want to fully use the available space in your viewport.

If the NO-EMPTY-SPACE is set to TRUE and there is empty space, the last browse column is widened to fill up the space. Also, if any browse column’s width attribute is changed or the browse’s width attribute is changed so that the last browse column is fully displayed in the browse’s viewport with empty space to its right, then the last browse column’s width is widened so that it fits within the viewport with no empty space and no horizontal scroll bar.

NO-EMPTY-SPACE never reduces the width of the last browse column.

NO-EMPTY-SPACE is ignored under the following circumstances:

- When the last browse column’s width is explicitly set at run time after the browse is realized.
- When the last browse column displays partially or entirely outside of the viewport.
- If NO-EMPTY-SPACE is set to FALSE, the last browse column’s width remains the same and is never changed by the AVM.
If you specify NO-EMPTY-SPACE for an individual browse, and the `-expandbrow` startup parameter is also specified, then the NO-EMPTY-SPACE attribute overrides `-expandbrow` for that browse.

When you use NO-EMPTY-SPACE, the original width of the last browse column is not remembered. For example, if the original width of the last browse column is 48 pixels, the DEFINE BROWSE statement has NO-EMPTY-SPACE specified, and if at run time there are 12 blank pixels as empty space in the right side of the viewport, the last browse column’s width is increased to 60 pixels, so there is no blank space in the browse.

If later at run time, the width of a column other than the last column is increased, a horizontal scroll bar is added to the browse. The width for the last browse column remains at 60 pixels.

### NO-FOCUS attribute
(Windows only)

Determines whether a button can accept focus. A button for which the NO-FOCUS attribute is TRUE will not take focus when the mouse is clicked on it and it will not accept keyboard input. Also, the AVM will not generate ENTRY or LEAVE events for the button. NO-FOCUS buttons behave similarly to standard Windows toolbar buttons.

This attribute must be set before the button is realized. The default value is FALSE.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** BUTTON widget

A button for which the NO-FOCUS attribute is TRUE will not be added to its parent frame’s tab order. If the NO-FOCUS attribute is switched from TRUE to FALSE before the button is realized, the button will be added to the end of its parent frame’s tab order. Switching the NO-FOCUS option from FALSE to TRUE before realization will remove the button from its parent frame’s tab order.

The mnemonic key (ALT accelerator) for a widget will not work if the widget is removed from the tab order. Also, because the widget is not in the tab order, pressing TAB will not change focus from the widget.

Keep in mind that if a frame that contains a NO-FOCUS button does not itself have focus, the frame will not receive focus when the button is pushed. In this situation, frame entry or leave events are not generated. Focus stays on the current widget when a NO-FOCUS button is pushed, even across multiple frames in a window.

### NONAMESPACE-SCHEMA-LOCATION attribute

Determines the location the XML Schema file to validate when elements do not contain a namespace.
NO-SCHEMA-MARSHAL attribute

Applies to: CHARACTER
Access: Readable/Writable
Applies to: X-document object handle, SAX-reader object handle

Contains the XML Schema file location for elements with no namespace.

This attribute specifies a single schema location. It defaults to an empty string ("").

NO-SCHEMA-MARSHAL attribute

Set to TRUE to exclude schema information when marshaling data for a temp-table parameter. The temp-table may be an independent temp-table or a member of a ProDataSet object.

This attribute is supported only for backward compatibility. Use the SCHEMA-MARSHAL attribute instead.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: Temp-table object handle

The receiving procedure must have a temp-table definition in which to receive the temp-table. If the receiving temp-table is dynamic, and it does not have a definition, the AVM generates a run-time error.

Where this attribute suppresses index descriptions and all field information when marshaling data, the AVM cannot perform field validation. Be sure the schema of both the source and target temp-tables is the same.

The NO-SCHEMA-MARSHAL attribute corresponds to the SCHEMA-MARSHAL attribute with a value of "NONE".

Note: If you specify both the NO-SCHEMA-MARSHAL attribute and the SCHEMA-MARSHAL or MIN-SCHEMA-MARSHAL attribute for an individual temp-table, the AVM uses the attribute you most recently specified.

Setting this attribute overrides the setting of the Temp-table Schema Marshal (-ttmarshal) startup parameter for an individual temp-table parameter. For more information about this startup parameter, see OpenEdge Deployment: Startup Command and Parameter Reference.

See also: MIN-SCHEMA-MARSHAL attribute, SCHEMA-MARSHAL attribute

NO-VALIDATE attribute

Specifies that the AVM ignore the validation conditions in the schema for all fields in a dynamic browse.
**NODE-VALUE attribute**

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BROWSE widget

This attribute is readable by both static and dynamic browses, and writeable only by dynamic browses.

If TRUE, the AVM does not run the validation for dynamic browse columns. If FALSE, the AVM runs the validation. The default value is FALSE.

**Note:** For a static browse, this attribute is set in the DEFINE BROWSE statement using the NO-VALIDATE option.

---

**NODE-VALUE attribute**

Returns (or sets) the value of the XML node.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: X-noderef object handle

The following example demonstrates the use of the NODE-VALUE attribute:

```plaintext
IF hNoderef:NODE-VALUE = "500" THEN
  hNoderef:NODE-VALUE = "1000".
```

---

**NODE-VALUE-TO-LONGCHAR( ) method**

Copies the contents of an XML X-noderef node to a LONGCHAR, and optionally converts the contents to a specific code page.

Return type: LOGICAL
Applies to: X-noderef object handle

**Syntax**

```plaintext
NODE-VALUE-TO-LONGCHAR( longchar [ codepage ] )
```

*longchar*

An expression of type LONGCHAR.

*codepage*

A character-string expression that evaluates to the name of a code page. The name you specify must be a valid code page name available in the DLC/convmap.cp file. If you do not specify *codepage* and the code page of *longchar* is fixed (that is, set using the
**NODE-VALUE-TO-MEMPTR( ) method**

Fix-CODEPAGE statement), the AVM converts *longchar* to the fixed code page. If you do not specify *codepage* and the code page of *longchar* is not fixed, the AVM converts *longchar* to the code page specified by \(-\text{cpinternal}\). If you specify *codepage* and the code page of *longchar* is fixed, they must agree. Otherwise, the AVM raises a run-time error.

**NODE-VALUE-TO-LONGCHAR( )** frees the memory currently allocated by *longchar* (if any), allocates sufficient memory to the LONGCHAR to accommodate the node, and copies the node to the LONGCHAR.

If X-NODEREF:NODE-VALUE is the empty string (""), the resulting *longchar* has a size of zero length.

For more information on accessing XML documents using the Document Object Model (DOM) interface, see *OpenEdge Development: Working with XML*.

---

**NODE-VALUE-TO-MEMPTR( ) method**

Copies the contents of an XML X-noderef node to a MEMPTR. This makes it easier to manipulate when its length exceeds the ABL limit for text strings, which is approximately 32K.

**Return type:** LOGICAL  
**Applies to:** X-noderef object handle

**Syntax**

```
NODE-VALUE-TO-MEMPTR( memptr )
```

*memptr*

An expression of type MEMPTR.

**NODE-VALUE-TO-MEMPTR( )** frees the memory currently allocated by *memptr* (if any), allocates sufficient memory to the MEMPTR to accommodate the node, and copies the node to the MEMPTR.

If X-NODEREF:NODE-VALUE is "" (the empty string), the resulting *memptr* has a size of zero.

**Note:** When you no longer need the memory used by *memptr*, you must free it yourself. To do so, use the SET-SIZE statement.

The following fragment uses NODE-VALUE-TO-MEMPTR( ) to access a large text node in chunks:
NORMALIZE( ) method

Normalizes TEXT and ATTRIBUTE nodes in the full depth of the sub-tree under this XML node.

Return type:  LOGICAL

Applies to:  X-noderef object handle

Syntax

```
NORMALIZE ( )
```

The NORMALIZE( ) method normalizes TEXT nodes by removing empty TEXT nodes and merging adjacent TEXT nodes. Thus, only structure node types (such as ELEMENT, CDATA-SECTION, and so on) separate TEXT nodes. The NORMALIZE( ) method also normalizes white space in ATTRIBUTE nodes according to the rules defined by the XML specification.

NUM-BUFFERS attribute

The number of buffers in a query or ProDataSet object.

Data type:  INTEGER

Access:  Readable

Applies to:  ProDataSet object handle, Query object handle

NUM-BUTTONS attribute

The number of items in a radio set.
**NUM-CHILD-RELATIONS attribute**

The number of relations for which the buffer is the parent. A buffer may be a parent in multiple relations, but a child in only one.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** RADIO-SET widget

**NUM-CHILDREN attribute**

Returns the number of child nodes below the node referred to by a node reference. Attributes are not counted since they are not considered children of a node.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** X-document object handle, X-noderef object handle

The following example demonstrates getting all the child nodes from the XML node referenced by hNoderef using the NUM-CHILDREN attribute:

```plaintext
REPEAT jx = 1 TO hNoderef:NUM-CHILDREN:  
hNoderef:GET-CHILD(hNoderefChild, jx).
  . . .  
END.
```

**NUM-COLUMNS attribute**

The number of columns in a browse. This number includes hidden as well as visible columns.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** BROWSE widget

**NUM-DROPPED-FILES attribute**  
*(Windows only; Graphical interfaces only)*

Indicates the number of files dropped in the last drag-and-drop operation performed on the widget.
NUM-ENTRIES attribute

The number of entries in a color table or font table.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable/Writeable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>COLOR-TABLE system handle, FONT-TABLE system handle</td>
</tr>
</tbody>
</table>

This attribute returns zero (0) in character interfaces because colors and fonts are not supported for character interfaces.

NUM-FIELDS attribute

The number of fields defined in the buffer’s table.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>Buffer object handle</td>
</tr>
</tbody>
</table>

NUM-FORMATS attribute

The number of formats available for reading the data currently stored in the clipboard.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>CLIPBOARD system handle</td>
</tr>
</tbody>
</table>

If there are no formats available, the attribute returns 0. For more information, see the reference entry for the CLIPBOARD system handle.

NUM-HEADER-ENTRIES attribute

The number of SOAP-header-entryref object entries attached to the SOAP-header object.
NUM-ITEMS attribute

The number of entries in a combo box, SAX-attributes object, or selection list.

Data type: INTEGER
Access: Readable
Applies to: SOAP-header object handle

NUM-ITEMS attribute

For browses, this attribute applies only to combo-box browse columns.

NUM-ITERATIONS attribute (data objects)

Indicates how many levels deep you are in a recursive FILL of a ProDataSet.

Data type: INTEGER
Access: Readable
Applies to: Buffer object handle

Syntax

```
NUM-ITERATIONS ( level )
```

<table>
<thead>
<tr>
<th>level</th>
</tr>
</thead>
</table>

An integer expression that indicates how many levels deep you are in a recursion.

As a recursive ProDataSet FILL is proceeding, it creates clones of the relevant buffers, relations, queries and data-sources for each level of recursion. As a new record is added to the ProDataSet, it fires FILL events on the recursed, cloned buffer. From inside the event handler, you may want to see previous iterations of the buffer, its parent, grandparent, great-grandparent, and so on. NUM-ITERATIONS indicates the level of the recursion.

If the buffer object handle does not point to a ProDataSet temp-table or is not part of a recursive data-relation, NUM-ITERATIONS returns the Unknown value (?).
NUM-ITERATIONS attribute (widget objects)

The number of currently visible foreground iterations for a frame or the number of rows currently visible in a browse widget.

Data type: INTEGER
Access: Readable
Applies to: BROWSE widget, FRAME widget

NUM-LINES attribute

The number of lines in an editor widget.

Data type: INTEGER
Access: Readable
Applies to: EDITOR widget

Lines are substring of the editor field or variable that are terminated by end-of-line characters. The editor inserts end-of-line characters at the current cursor position it receives a RETURN event.

NUM-LOCKED-COLUMNS attribute

The number of visible leading columns locked in a browse widget. If a locked column is hidden, the next visible non-locked column in the browse will then become locked.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget

When you use the horizontal scrollbar to scroll columns in the browse, locked columns do not move. For example, if NUM-LOCKED-COLUMNS is 3, then the three leftmost columns in the browse are locked.

Note: In character mode, this attribute can only be set before the widget is realized.

NUM-LOG-FILES attribute

The number of rolled over log files to keep on disk at any one time, for ABL session, including the current log file.
NUM-MESSAGES attribute

The number of error messages currently available through the specified system handle.

Data type: INTEGER
Access: Readable
Applies to: COMPILER system handle, ERROR-STATUS system handle

For the COMPILER system handle, this value represents the number of compilation errors detected during the preceding ABL source code compilation.

For the ERROR-STATUS system handle, this value represents the number of messages returned for the ERROR condition raised in a statement run with the NO-ERROR option.

NUM-PARAMETERS attribute

The number of parameters expected.
**NUM-REFERENCES attribute**

The number of references to a buffer, ProDataSet, or temp-table object that is defined as a parameter to which reference-only objects are bound.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer object handle, ProDataSet object handle, Temp-table object handle

Use this attribute to determine whether a buffer, ProDataSet, or temp-table object is referenced by another procedure before you delete the defining procedure or the referenced object itself (if it is a dynamic object).

If the buffer, ProDataSet, or temp-table object is not referenced by any other procedure (or other such object), this attribute returns 0. Otherwise, this attribute returns the number of procedures (or other such objects) currently referencing the object.

This attribute applies to objects defined as reference-only parameters, not shared objects.

**See also:** DEFINE DATASET statement (REFERENCE-ONLY option), DEFINE TEMP-TABLE statement (REFERENCE-ONLY option), DELETE OBJECT statement, DELETE PROCEDURE statement, RUN statement

**NUM-RELATIONS attribute**

The number of data-relation objects in a ProDataSet object.

**Data type:** INTEGER  
**Access:** Readable/Writable  
**Applies to:** Call object handle

Syntax

```
NUM-PARAMETERS ( integer-expression )
```

`integer-expression`

An integer expression indicating the number of parameters expected. The default is zero.

Whenever NUM-PARAMETERS is set, all existing parameters, including those from earlier uses of SET-PARAMETER, are cleared and deallocated.

If there are parameters to be passed, NUM-PARAMETERS must be set before the INVOKE() method is executed.

When you are getting a parameter, set NUM-PARAMETERS to the actual number of parameters to be passed, which might vary if one or more trailing parameters are optional.

When you are setting an attribute, use NUM-PARAMETERS 1.
NUM-REPLACED attribute

Data type: INTEGER
Access: Readable
Applies to: ProDataSet object handle

Indicates the number of occurrences replaced by the last REPLACE( ) method executed for the Editor.

Data type: INTEGER
Access: Readable
Applies to: EDITOR widget

If the Editor has not yet been realized, the attribute has the Unknown value (?)..

NUM-RESULTS attribute

The number of rows currently in a query’s result list.

Data type: INTEGER
Access: Readable
Applies to: Query object handle

Note: The NUM-RESULTS attribute corresponds to the NUM-RESULTS function.

See also: NUM-RESULTS function

NUM-SELECTED-ROWS attribute

The number of rows currently selected in a browse widget.

Data type: INTEGER
Access: Readable
Applies to: BROWSE widget

A browse can have more than one row selected only if the MULTIPLE attribute is TRUE.

NUM-SELECTED-WIDGETS attribute

The number of top-level widgets in a frame or window that the user has selected for direct manipulation.
NUM-SOURCE-BUFFERS attribute

The number of source buffers in the Data-source object.

Data type: INTEGER
Access: Readable
Applies to: Data-source object handle

NUM-TABS attribute

The number of widgets in the field group with tab positions.

Data type: INTEGER
Access: Readable
Applies to: FIELD-GROUP widget

NUM-TO-RETAIN attribute

The number of frame iterations to retain when a down frame scrolls to a new set of iterations.

Data type: INTEGER
Access: Readable
Applies to: FRAME widget

This value is set using the RETAIN option of the Frame phrase.

NUM-TOP-BUFFERS attribute

The number of top-level buffers in a ProDataSet object.

Note: A top-level buffer is a ProDataSet object buffer that is not a child in any active data relation. There may be one or more top-level buffers in a ProDataSet object.
NUM-VISIBLE-COLUMNS attribute

Data type: INTEGER
Access: Readable
Applies to: ProDataSet object handle

NUM-VISIBLE-COLUMNS attribute

Returns the number of visible columns in a browse.

Data type: INTEGER
Access: Readable
Applies to: BROWSE widget

NUMERIC-DECIMAL-POINT attribute

The character that represents, in formatted text, a number’s decimal point.

Data type: CHARACTER
Access: Readable
Applies to: SESSION system handle

NUMERIC-FORMAT attribute

How to interpret commas and periods within numeric values.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: SESSION system handle

The possible values are "American", "European" or a character string consisting of the thousands separator followed by the decimal point. This attribute provides the same functionality as the European Numeric Format (-E) parameter.

Note: Although NUMERIC-FORMAT remains writable, it accepts only the values “European” and “American.” To change the thousands separator or the decimal point in formatted text, use the new SET-NUMERIC-FORMAT( ) method of the SESSION system handle.

NUMERIC-SEPARATOR attribute

The character that represents, in formatted text, a number’s thousands separator.
ON-FRAME-BORDER attribute

Indicates whether the last event was a mouse event that occurred on a frame border.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** LAST-EVENT system handle

ORDINAL attribute

Specifies the number of the entry point (the n<sup>th</sup> routine) of the Windows Dynamic Link Library (DLL) to invoke.

**Data type:** INTEGER  
**Access:** Readable/Writable  
**Applies to:** Call object handle

Using the call object handle, there are two alternate methods for invoking a DLL routine—either by specifying the routine’s name with the CALL-NAME attribute or by specifying the routine’s position in the DLL with the ORDINAL attribute. You can specify an ORDINAL value or a CALL-NAME value, but not both. Specifying an ORDINAL value and setting CALL-NAME at the same time causes the AVM to raise error at run time.

The AVM raises error at run time if the ORDINAL entry point does not match any routine in a given DLL.

For UNIX shared library routines, this option does not apply and is ignored.

**See also**  
CALL-NAME attribute

ORIGIN-HANDLE attribute

Returns the handle of the temp-table in the original source ProDataSet object that corresponds to the temp-table currently associated with this temp-table handle.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Temp-table object handle

The AVM uses this value to match up temp-tables in a MERGE-CHANGES operation.
ORIGIN-ROWID attribute

Returns the ROWID of the row in the original before-image table that corresponds to the row in the change table currently associated with this buffer handle.

**Data type:** ROWID  
**Access:** Readable  
**Applies to:** Buffer object handle

The AVM uses this value to match up temp-table rows in a MERGE-CHANGES operation.

OVERLAY attribute

Indicates whether the frame can overlay other frames on the display.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** FRAME widget

If the OVERLAY attribute is TRUE, the frame can overlay any other frame that does not have its TOP-ONLY attribute set to TRUE.

OWNER attribute

The handle of the widget that owns a menu widget.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** MENU widget

For a menu bar, the OWNER attribute returns the window with which the menu bar is associated. For a pop-up menu, the OWNER attribute returns the widget with which the menu is associated.

OWNER-DOCUMENT attribute

Returns the handle of the owning document of a node.
Data type: HANDLE  
Access: Readable  
Applies to: X-noderef object handle

The following example demonstrates the use of the OWNER-DOCUMENT attribute:

```
DEFINE VARIABLE hDoc AS HANDLE NO-UNDO.
DEFINE VARIABLE hDoc2 AS HANDLE NO-UNDO.

hDoc:GET-DOCUMENT-ELEMENT(hNoderef).
hDoc2 = hNoderef:OWNER-DOCUMENT.

/* At this point, hDoc2 and hDoc should be the same. */
```

PAGE-BOTTOM attribute

Indicates whether a frame is a footer frame in paged output.

Data type: LOGICAL  
Access: Readable/Writeable  
Applies to: FRAME widget

If PAGE-BOTTOM is TRUE, the frame appears at the end of each page of output.

PAGE-TOP attribute

Indicates whether a frame is a header frame in paged output.

Data type: LOGICAL  
Access: Readable/Writeable  
Applies to: FRAME widget

If PAGE-TOP is TRUE, the frame appears at the beginning of each page of output.

PARAMETER attribute

The value of the Parameter (-param) startup parameter specified for the current session.

Data type: CHARACTER  
Access: Readable  
Applies to: SESSION system handle

Use the Parameter (-param) parameter to specify a character string that can be accessed from ABL procedures. The AVM does not check the value of the PARAMETER attribute and you can use the parameter and attribute to store any arbitrary string value.
PARENT attribute

The handle of the parent of a widget.

**Data type:** HANDLE

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU-ITEM widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, SHADOW-WINDOW widget, WINDOW widget

This attribute is read-only for field groups.

For field-level widgets, the parent widget is the field group that contains the widget. For field groups, the parent widget is the frame that contains the field group. For frames, the parent widget is the window or field group that contains the frame. For a submenu or menu item, the parent widget is the menu or submenu that contains the submenu or menu item.

For ABL windows, the parent widget is another window that parents this window. The main feature of these window families is that when the parent window is minimized, all of its child windows are hidden. .NET forms have a similar feature for parenting forms to other forms using the Owner property or the AddOwnedForm() method, which in OpenEdge are both provided by the Progress.Windows.Form class.

However, .NET form families exhibit one feature that ABL window families do not share—child forms never appear behind the parent form. The reason is that ABL window family behavior results from a native OpenEdge implementation that is different from the feature provided by Windows. In an ABL session, the .NET form and ABL window family mechanisms continue to work differently for forms and windows as long as .NET forms only parent forms and ABL windows only parent windows.

However, you can also parent .NET forms and ABL windows to each other using the PARENT attribute on the shadow window of a .NET form or the PARENT attribute on an ABL window. You can obtain the handle to the shadow window of a .NET form that you want to be a child or a parent from the value of the ProWinHandle property on the form (provided by Progress.Windows.Form). Then:

- To parent the form as a child of a window, set the form shadow window’s PARENT attribute to the handle of the ABL window you want to become the form’s parent.

- To parent a child window to this form, set the PARENT attribute of the ABL window you want to become the form’s child to the shadow window handle of this parent form.

When you establish parent/child relationships like this between .NET forms and ABL windows, both the forms and windows in these mixed form and window families conform to the ABL window family mechanism (which allows the children to appear behind the parent) instead of conforming to the .NET form family mechanism (which forces the children to appear in front of the parent).
Note: You cannot use the PARENT attribute of form shadow windows to parent .NET forms to other .NET forms in an ABL session. You can only establish standard .NET parent/child relationships among forms using the Owner properties or AddOwnerForm( ) methods of .NET forms.

See also: Progress.Windows.Form class, ProWinHandle property

**PARENT-BUFFER attribute**

Returns the buffer handle of the parent member of the data-relation object.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Data-relation object handle

**PARENT-RELATION attribute**

Returns the handle to the SELECTION data-relation object for the parent of this buffer. Since a buffer may be a child in only one relation, there can be only one parent for any buffer.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Buffer object handle

**PARSE-STATUS attribute**

The current status of a SAX parse.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** SAX-reader object handle

The default value is SAX-UNINITIALIZED.

The values that PARSE-STATUS can assume are described in Table 92.

<table>
<thead>
<tr>
<th>This value . . .</th>
<th>Indicates . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAX-UNINITIALIZED</td>
<td>No parsing has occurred.</td>
</tr>
<tr>
<td>SAX-RUNNING</td>
<td>Parsing has begun.</td>
</tr>
</tbody>
</table>
**Table 92: PARSE-STATUS attribute values (2 of 2)**

<table>
<thead>
<tr>
<th>This value . . .</th>
<th>Indicates . . .</th>
</tr>
</thead>
</table>
| SAX-COMPLETE     | Parsing has begun and one of the following has occurred:  
|                  | • The parser has determined that there are no more tokens in the XML source.  
|                  | • The application has stopped the parser by calling the STOP-PARSING( ) method. |
| SAX-PARSER-ERROR | One of the following has occurred:  
|                  | • The parser could not start or could not continue. Perhaps the parser could not be loaded, the XML source could not be found, the XML source was invalid, etc.  
|                  | • The parser started, but a callback executed a RETURN ERROR statement. |

**PASSWORD-FIELD attribute**

Displays password data in a field as a series of fill characters.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** FILL-IN widget

If TRUE, the current value of a fill-in field or any character value typed into the fill-in field is displayed as a series of fill characters. The default value is FALSE.

In Windows GUI platforms, the default fill character is the asterisk (*). On non-Windows GUI or character platforms, the default fill character is a blank.

**PATHNAME attribute**

The absolute or relative pathname of the file specified by the FILE-NAME attribute of the FILE-INFO Handle.

- **Data type:** CHARACTER
- **Access:** Readable
- **Applies to:** FILE-INFO system handle

If the FILE-NAME attribute specifies a simple filename or relative pathname, this attribute returns a relative pathname based on the PROPATH. Otherwise, it returns the absolute pathname specified in FILE-NAME.
**PBE-HASH-ALGORITHM attribute**

A text string containing the name of the hash algorithm to use with the GENERATE-PBE-KEY function to generate a password-based encryption key. The default value is “SHA-1”.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** SECURITY-POLICY system handle

ABL supports the following hash algorithms:
- United States Government Secure Hash Algorithm (SHA-1)  
- RSA Message Digest Hash Algorithm (MD5)

You are responsible for generating, storing, and transporting this value.

**See also:** MD5-DIGEST function, SHA1-DIGEST function

**PBE-KEY-ROUNDS attribute**

The number of hash algorithm iterations to perform in the GENERATE-PBE-KEY function to generate a password-based encryption key. The value must be a positive integer. The default value is 1000.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** SECURITY-POLICY system handle

You are responsible for generating, storing, and transporting this value.

**Note:** Setting the PBE-KEY-ROUNDS attribute to an extremely large number can significantly slow the performance of the GENERATE-PBE-KEY function.

**PERSISTENT attribute**

Indicates whether the procedure is persistent.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Call object handle, Procedure object handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

The PERSISTENT attribute is TRUE when the RUN statement that executes a procedure is invoked with the PERSISTENT option. Otherwise, it is FALSE.
When a dynamic invoke returns and PERSISTENT is TRUE, the IN-HANDLE attribute contains a handle to the running persistent procedure.

When a Windows DLL or UNIX shared library is invoked dynamically and PERSISTENT is TRUE, the DLL or shared library remains loaded in memory until the AVM exits or the session executes the RELEASE EXTERNAL statement.

Returns TRUE for a Web service procedure.

**See also** IN-HANDLE attribute, INVOKE( ) method (Handle), RELEASE EXTERNAL statement, RUN statement

---

**PERSISTENT-CACHE-DISABLED attribute**

Indicates whether WebClient disables the saving of security cache attribute values between sessions (TRUE) or not (FALSE).

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** CODEBASE-LOCATOR system handle

When TRUE, KEEP-SECURITY-CACHE will be FALSE.

---

**PERSISTENT-PROCEDURE attribute**

For the AppServer, this attribute returns the proxy remote persistent procedure handle of the remote procedure that contains the internal procedure executed for the specified asynchronous request. For Web services, this attribute returns the Web service procedure object handle.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Asynchronous request object handle

This handle is the same as the handle specified by the IN proc-handle option of the RUN statement that executes this request. If the request is running a remote external (not internal) procedure, this attribute contains an invalid handle.

---

**PFCOLOR attribute**  
*(Character interfaces only)*

The color number of the color of a widget that has input focus. The edge color of a rectangle widget.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget (browse, column, and cell), BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN
widget, FRAME widget, MENU widget, MENU-ITEM widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, TOGGLE-BOX widget, WINDOW widget

The color number represents an entry in the color table maintained by the COLOR-TABLE handle.

For field-level widgets that receive focus, the PFCOLOR attribute specifies the input color for the widget. In windows, the PFCOLOR attribute specifies the color inherited by menu items in the menu bar when they are chosen, if the menu items don’t already have the PFCOLOR specified.

For browse widgets, this color represents the input color for the focused cell.

For more information on widget color, see the DCOLOR attribute.

PIXELS-PER-COLUMN attribute

The number of pixels in each column of the display.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** SESSION system handle

This value is also the pixel size of a horizontal character unit, and depends on the resolution of the display and the size of the default system font.

PIXELS-PER-ROW attribute

The number of pixels in each row of the display.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** SESSION system handle

This value is also the pixel size of a vertical character unit, and depends on the resolution of the display and the size of the default system font.

POPUP-MENU attribute

The pop-up menu associated with a widget.

**Data type:** HANDLE

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget,
RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget, WINDOW widget

The value you assign to POPUP-MENU must be the handle of a previously defined menu whose POPUP-ONLY attribute is TRUE.

**POPUP-ONLY attribute**

Indicates whether a menu is pop-up or a menu bar.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** MENU widget

Set the POPUP-ONLY attribute to TRUE to use the menu as a pop-up menu. Otherwise, the menu is a menu bar that you can associate with a window. FALSE is the default value. You can set this attribute only before the menu is realized.

**POSITION attribute**

The position of a buffer-field within the database record.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer-field object handle

*Note:* The POSITION attribute applies to OpenEdge databases only.

**PREFER-DATASET attribute**

Specifies whether the AVM ignores modifications to the data currently in the data source when saving changes from a ProDataSet temp-table buffer to the associated data source using the SAVE-ROW-CHANGES( ) method. The default value is FALSE.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** Data-source object handle

If TRUE, the AVM ignores the data currently in the data source and automatically accepts the data from the ProDataSet temp-table buffer.

If FALSE, the AVM compares the before-image of the data in the ProDataSet temp-table buffer, saved while tracking changes for the buffer, to the corresponding data source buffer to determine whether the data in the data source has changed since being read. The AVM evaluates any data source changes to determine whether or not a data conflict exists based on the MERGE-BY-FIELD attribute setting (that is, on either a field-to-field or buffer-to-buffer basis).
PREPARED attribute

This attribute returns TRUE if the TEMP-TABLE-PREPARE( ) method has been called with no subsequent CLEAR( ) method. That is, it is true when the temp-table is in the PREPARED state.

Data type: LOGICAL
Access: Readable
Applies to: Temp-table object handle

PREPARE-STRING attribute

The character string passed to the most recent QUERY-PREPARE. If QUERY-PREPARE was not called, or the query was just opened with the OPEN QUERY statement, PREPARE-STRING has the Unknown value (?).

Data type: CHARACTER
Access: Readable
Applies to: Query object handle

For an example, see the reference entry for the INDEX-INFORMATION attribute.

PREV-COLUMN attribute

The handle of the previous sibling, in physical order, of the current browse column whether or not the column is visible. The browse MOVE-COLUMN method changes the physical order of columns and updates this attribute accordingly.

Data type: HANDLE
Access: Readable
Applies to: BROWSE widget (column)

PREV-SIBLING attribute

The previous entry in the list of handles, relative to a given handle.

Note: Returns the Unknown value (?) for a Web service procedure.

Data type: HANDLE
Access: Readable
Applies to: Asynchronous request object handle, BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU-ITEM widget, Procedure
PREV-TAB-ITEM attribute

The handle of the previous widget in the tab order of a field group relative to the specified widget.

**Data type:** HANDLE

**Access:** Readable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

The PREV-TAB-ITEM attribute returns the Unknown value (?) for a widget that is at the beginning of the tab order in a field group.

object handle, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, Server object handle, SLIDER widget, Socket object handle, Server socket object handle, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

Table 93 summarizes the value of PREV-SIBLING for each relevant handle type.

<table>
<thead>
<tr>
<th>Handle type</th>
<th>Value of PREV-SIBLING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asynchronous Request</td>
<td>The handle of the previous asynchronous request submitted for execution on the AppServer or Web Server that is running the specified request.</td>
</tr>
<tr>
<td>Procedure</td>
<td>The handle of the previous persistent procedure in the current ABL session. If the current procedure is a proxy for a persistent procedure running on an AppServer or for a Web service, specifies the previous procedure object bound to the same server handle.</td>
</tr>
<tr>
<td>Server</td>
<td>The previous server handle created in the current ABL session (independent of subtype).</td>
</tr>
<tr>
<td>Socket and Server-socket</td>
<td>The previous socket handle in the chain of socket handles for the current ABL session. Returns the Unknown value (?) for the first handle in the chain.</td>
</tr>
<tr>
<td>Widget</td>
<td>The handle of the previous widget in the widget list.</td>
</tr>
</tbody>
</table>

**Note:** A widget must first be realized before it can become part of the list. A hidden widget cannot become part of the list since it is not realized. A widget that is already part of the list can be hidden and it remains part of the list.

If the given handle is the first handle in the list, PREV-SIBLING assumes the value of an invalid handle. To check the validity of a handle, use the VALID-HANDLE function.

See also: NEXT-SIBLING attribute
**PRIMARY attribute**

This attribute sets or returns the name of the temp-table’s primary index. PRIMARY can only be updated before the TEMP-TABLE-PREPARE( ) method has been called. It returns the Unknown value (?) if the temp-table is not in a PREPARED state.

**Data type:** CHARACTER  
**Access:** Readable/Writable  
**Applies to:** Temp-table object handle

**PRINTER-CONTROL-HANDLE attribute**  
(Windows only)

The default context for print jobs.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

The print context is an integer identifier for a set of values that define a printer and setup for that printer in Windows. You can establish a print context using the Print dialog box. The SYSTEM-DIALOG PRINTER-SETUP statement allows you to display the Print dialog box and set a print context. This print context is used by the OUTPUT TO PRINTER statement to direct output to a printer.

If the PRINTER-CONTROL-HANDLE attribute contains zero (0) or the Unknown value (?), the print context is the default print context in Windows as set in the Windows Control Panel. You can assign any integer value to this attribute, but the result of the assignment will be to set the attribute value to 0 and to release any Windows resources related to the previous print context.

**PRINTER-HDC attribute**

A handle to the current Windows device context for a print job.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** SESSION system handle

The printer device context handle is the Windows Handle to a Device Context (HDC). The value of the PRINTER-HDC attribute is meaningless when the SESSION:PRINTER-CONTROL-HANDLE has a value of zero (0) or the Unknown value (?). For more information, see the reference entry for the PRINTER-CONTROL-HANDLE attribute.
PRINTER-NAME attribute
(Windows only)

The name of the currently selected printer in Windows platforms, and the Unknown value (?) on other platforms.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: SESSION system handle

Use this attribute to set the printer name in the default print context. The value of PRINTER-NAME is the name Windows uses to identify a printer. The specified printer must be defined in the Windows Registry. If the specified printer is not defined in the Windows Registry, the value of PRINTER-NAME is not modified. You must specify network printers in Universal Naming Convention format.

Use the GET-PRINTERS( ) method to get the list of printers currently defined in the Windows Registry.

If you use the SYSTEM-DIALOG PRINTER-SETUP statement to set the printer name, this attribute assumes the modified value.

PRINTER-PORT attribute
(Windows only)

The currently selected printer port in Windows platforms, and the Unknown value (?) on other platforms.

Data type: CHARACTER
Access: Readable
Applies to: SESSION system handle

PRINTER-PORT assumes the value for printer port that Windows defines. If someone modifies the value using the SYSTEM-DIALOG PRINTER-SETUP command, PRINTER-PORT assumes the modified value.

PRIVATE-DATA attribute

An arbitrary string associated with the handle of an object or widget.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: Asynchronous request object handle, BROWSE widget (browse and column), Buffer-field object handle, Buffer object handle, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, Data-relation object handle, Data-source object handle, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU widget, MENU-ITEM widget, Procedure object
handle, ProDataSet object handle, Query object handle, RADIO-SET widget, 
RECTANGLE widget, SAX-attributes object handle, SAX-reader object 
handle, SELECTION-LIST widget, Server object handle, Server socket 
object handle, SLIDER widget, SOAP-header object handle, 
SOAP-header-entryref object handle, Socket object handle, Stream object 
handle, SUB-MENU widget, Temp-table object handle, TEXT widget, 
TOGGLE-BOX widget, WINDOW widget

Use this attribute any way you want. The AVM does not check the value of this attribute.

PROCEDURE-NAME attribute

A string specifying the name of the remote procedure executed to instantiate the specified 
asynchronous request handle.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** Asynchronous request object handle

This name is the same as the *extern-proc-name*, *intern-proc-name*, or VALUE option used to specify the remote procedure executed in the asynchronous RUN statement.

PROGRESS-SOURCE attribute

*(Character interfaces only)*

How an editor widget wraps lines of ABL source code that are longer than the widget’s display width.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** EDITOR widget

Set this attribute to TRUE when reading ABL source code into the widget. This preserves the ABL syntax for the ABL compiler.

When set to TRUE, the editor widget splits long lines by putting a tilde (~) and hard return at the end of the display line and continuing the text with column 1 of the next display line. The line wrapping occurs only when a READ-FILE( ) or INSERT-FILE( ) method is used to bring text into the widget. When set to FALSE, the editor widget splits long lines by inserting a HARD-RETURN before the last word and moving the last word onto the next display line. FALSE is the default setting.

PROXY attribute

Indicates whether a procedure handle is a proxy persistent procedure handle.
PROXY-PASSWORD attribute

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** Procedure object handle

If PROXY is TRUE, the procedure handle is a proxy handle for a persistent procedure running remotely in the context of an AppServer.

PROXY is always FALSE on the THIS-PROCEDURE handle by definition.

Returns TRUE for a Web service procedure.

For more information on the AppServer, see *OpenEdge Application Server: Developing AppServer Applications*.

---

PROXY-PASSWORD attribute

Authenticates an AppServer or Web service client to the HTTP-based proxy server.

**Data type:** Character  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

This attribute corresponds to the -proxyPassword startup parameter. If -proxyPassword is not specified on the command line, this attribute has the Unknown value (?) until it is set.

This attribute is validated during the CONNECT( ) method (for an AppServer and a Web service). If PROXY-PASSWORD is invalid, the CONNECT( ) method fails and the AVM issues an error message. If PROXY-USERID is not unknown and PROXY-PASSWORD is unknown, the AppServer CONNECT( ) method uses a blank proxy password. If SESSION:PROXY-USERID is unknown, the CONNECT( ) method ignores any value of PROXY-PASSWORD. PROXY-PASSWORD must be a string of up to 512 printable ASCII characters.

**See also:** PROXY-USERID attribute, *OpenEdge Deployment: Startup Command and Parameter Reference, OpenEdge Deployment: WebClient Applications*

---

PROXY-USERID attribute

Authenticates an AppServer or Web service client to the HTTP-based proxy server.

**Data type:** Character  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

This attribute corresponds to the -proxyUserid startup parameter. If -proxyUserid is not specified on the command line, this attribute has the Unknown value (?) until it is set.
This attribute is validated during the CONNECT( ) method (for an AppServer and a Web service). If PROXY-USERID is invalid, the CONNECT( ) method fails and the AVM issues an error message.

PROXY-USERID must be a string of up to 512 printable ASCII characters, including the space character.

See also: PROXY-USERID attribute, OpenEdge Deployment: Startup Command and Parameter Reference, OpenEdge Deployment: WebClient Applications

PUBLIC-ID attribute

This attribute returns the public ID of the external DTD from which an XML document was generated.

Data type: CHARACTER  
Access: Readable  
Applies to: X-document object handle

PUBLISHED-EVENTS attribute

A comma-separated list of ABL named events published by a particular procedure. Returns the empty string for a Web service procedure.

Note: ABL named events are completely different from the key function, mouse, widget, and direct manipulation events described in the “Handle-based Object Events Reference” section on page 1827. They are also different from the class events described in the “Class Events Reference” section on page 1953.

Data type: CHARACTER  
Access: Readable  
Applies to: Procedure object handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

ABL builds PUBLISHED-EVENT lists as the compiler encounters PUBLISH statements—specifically, PUBLISH statements that specify the event name as a quoted string and not as a CHARACTER variable expression, and that do not use the FROM option.

Note: PUBLISHED-EVENTS lists do not contain signatures of their named events. ABL assumes that the subscriber to a named event knows its signature.
The handle of the query connected to a browse widget, a buffer object, a data-relation object, or a data-source object.

**Data type:** HANDLE

**Access:** Readable/Writable

**Applies to:** BROWSE widget, Buffer object handle, Data-relation object handle, Data-source object handle

If you change the value of a browse’s QUERY attribute, you connect the browse to a different query, which contains a different set of records.

For a browse query in Windows platforms:

- The original query and the new query do not need to have the same underlying database fields.

- If the query is changed for a dynamic browse, the browse columns are removed. You should add new columns with the ADD-CALC-COLUMN, ADD-COLUMNS-FROM, and ADD-LIKE-COLUMN methods.

- If the query is changed for a static browse and the underlying fields are the same, the columns are not removed. However, if the underlying fields are not the same, the columns are removed. The columns are also removed if the QUERY attribute is set to the Unknown value (?). You should add new columns with the ADD-CALC-COLUMN, ADD-COLUMNS-FROM, and ADD-LIKE-COLUMN methods.

- Also, a query can now be attached to a static browse that was defined without the optional DISPLAY phrase.

For a browse query on Character Mode platforms:

- If the original query has database tables, the new query must have database tables. The new query can have different buffers as long as they correspond to the same database tables.

- If the original query has temp-tables, the new query must have temp-tables, not work tables.

- The original query and the new query must have the same number of tables.

For a buffer object, this attribute returns the handle to the query currently associated with the buffer (if any). If the buffer does not have an associated query, this attribute returns the Unknown value (?). This attribute is also read-only for a buffer object.

For a data-relation object, this attribute returns the handle to the default dynamic query for a child buffer in the relation. This automatically generated query expresses the relation between parent and child temp-tables, and lets you navigate the child records. This handle cannot be set, and the query cannot be modified except by using the WHERE-STRING attribute.

For a data-source object, this attribute associates a query with a dynamic Data-source object. To disassociate the query and Data-source object, set this attribute to the Unknown value (?). You can also use the FILL-WHERE-STRING attribute to override the WHERE clause in the query.
QUERY-CLOSE( ) method

Closes a query object.

**Return type:** LOGICAL

**Applies to:** Query object handle

**Syntax**

```
QUERY-CLOSE()
```

**Note:** A QUERY-CLOSE does not invalidate a previous QUERY-PREPARATE.

---

QUERY-OFF-END attribute

Indicates whether a query is positioned off either end of its result list (that is, either before the first record or after the last record).

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** Query object handle

The QUERY-OFF-END attribute corresponds to the QUERY-OFF-END function.

**Note:** ABL also provides an OFF-END event for when a query on a ProDataSet temp-table buffer is positioned past the last row. You can use this event to retrieve additional data source rows to add at the bottom of a ProDataSet temp-table (for example, in batches when there are too many data source rows to retrieve at one time). The OFF-END event is similar to the QUERY-OFF-END attribute, which is set to TRUE whenever the associated query object is positioned past the last row. The difference is that you must test the QUERY-OFF-END attribute for this condition at a specific place in your application code, whereas the OFF-END event procedure executes like a trigger whenever the event occurs. For more information about the OFF-END event on a ProDataSet temp-table query, see the “ProDataSet events” section on page 1846.

**See also:** QUERY-OFF-END function

---

QUERY-OPEN( ) method

Opens a query object.

**Note:** You must perform QUERY-PREPARATE on a query object before you perform QUERY-OPEN on it.

---

See also: FILL-WHERE-STRING attribute, WHERE-STRING attribute
QUERY-PREPARE( ) method

**Return type:** LOGICAL

**Applies to:** Query object handle

**Syntax**

```
QUERY-PREPARE ( predicate-expression )
```

A CHARACTER expression that evaluates to an OPEN QUERY ... FOR EACH statement without the OPEN QUERY ... You can also use a field phrase.

The QUERY-PREPARE method corresponds to the OPEN QUERY statement’s compilation phase. To open the query object, use the QUERY-OPEN method.

If the QUERY-PREPARE method encounters an error, it returns FALSE and generates an error message, but does not raise ERROR. If you use the QUERY-PREPARE method in a statement that uses the NO-ERROR option and an error occurs, the QUERY-PREPARE method returns FALSE and diverts the error to the ERROR-STATUS system handle. In either instance, ERROR-STATUS:ERROR returns FALSE. You can get information on the error through the GET-MESSAGE method of the ERROR-STATUS system handle, as usual.

**Note:** The QUERY-PREPARE method is compatible with indexed reposition of queries with joins. In `predicate-expression`, just include the INDEXED-REPOSITION option. For more information on the INDEXED-REPOSITION option, see the reference entry for the OPEN QUERY statement.

The following are examples:

```plaintext
hQuery:QUERY-PREPARE("FOR EACH Customer WHERE Customer.CustNum < 9").
```
Unless explicitly specified otherwise in the predicate-expression, the default record lock type for the QUERY-PREPARE method is NO-LOCK.

Like the FOR statement, the QUERY-PREPARE method predicate-expression supports the BREAK and BY options for sorting and accumulating data by break groups.

To test whether a break group has changed, you can use the FIRST-OF( ) method and LAST-OF( ) method of the query object handle.

The QUOTER function can be used to wrap character values with internal quotes, as in this example:

```
hQuery:QUERY-PREPARE("FOR EACH Customer WHERE Customer.Name = " + QUOTER(my-name)).
```

**Note:** The NAME attribute of the Temp-table object handle is writeable for dynamic and AVM-generated temp-tables. You might need to update a predicate-expression that references a renamed temp-table with new strings using the new table name.

**See also:** OPEN QUERY statement

### QUIT attribute

Indicates that a QUIT condition was returned from the AppServer as a result of processing the specified asynchronous request. Returns FALSE for an asynchronous request made on a Web service.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** Asynchronous request object handle

If the COMPLETE attribute is FALSE, the value of this attribute is the Unknown value (?). When the PROCEDURE-COMPLETE event is processed, this attribute is set to TRUE before the event procedure is executed if the remote request returned with an unhandled QUIT condition; otherwise, it is set to FALSE.
RADIO-BUTTONS attribute

The label and value associated with each radio button in a radio set.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** RADIO-SET widget

You can set this attribute to a comma-separated list containing the label/value pairs associated with each button. Each label and each value should be followed by a comma, as in "label1,value1,label2,value2,...labeln,valuen".

RAW-TRANSFER( ) method

Copies data to or from a buffer object with no interpretation. This method works like the RAW-TRANSFER statement.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle

**Syntax**

```
bh:RAW-TRANSFER ( to-mode, handle-expression )
```

**to-mode**

A logical specifying the direction of the data transfer. When `to-mode` is TRUE, data is transferred from `bh` to `handle-expression`. When `to-mode` is FALSE, data is transferred from `handle-expression` to `bh`.

**handle-expression**

An expression that evaluates to the handle of either a buffer or a buffer field.

When using the RAW-TRANSFER statement to copy from a buffer object that contains a BLOB or CLOB field, the AVM skips the BLOB or CLOB field and stores the Unknown value (?) in the BLOB or CLOB field of the target buffer object.

**See also:** RAW-TRANSFER statement

READ( ) method

Reads data from the socket.
**Return type:** LOGICAL  
**Applies to:** Socket object handle

**Syntax**

\[
\text{READ}( \text{buffer}, \text{position}, \text{bytes-to-read}, [\text{mode}] )
\]

**buffer**

A MEMPTR expression that identifies where the data which is read from the socket should be stored.

**position**

An integer expression greater than 0 that indicates the starting byte position within `buffer` into which information should be written.

**bytes-to-read**

An integer expression that specifies the number of bytes to be read from the socket.

**mode**

An optional integer expression that specifies how `bytes-to-read` should be interpreted. Table 94 shows the valid values for this parameter. The default value is `READ-EXACT-NUM (2)`.

**Table 94: Valid read modes for the READ( ) method**

<table>
<thead>
<tr>
<th>Compiler constant</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ-AVAILABLE</td>
<td>1</td>
<td>The READ( ) method will block until at least one byte has been read on the socket. It will read up to <code>bytes-to-read</code> bytes.</td>
</tr>
<tr>
<td>READ-EXACT-NUM</td>
<td>2</td>
<td>The READ( ) method will block until <code>bytes-to-read</code> bytes have been read from the socket.</td>
</tr>
</tbody>
</table>

READ( ) returns TRUE if the read operation succeeded normally and returns FALSE otherwise. An error can occur if:

- The position parameter is not greater than 0.
- Amount of information requested to read exceeds the size of buffer.
- Reading from the socket fails.

This read statement is a blocking read. If `mode` is `READ-EXACT-NUM`, this method returns when it has either read the requested number of bytes from the socket or an error occurs. If `mode` is `READ-AVAILABLE`, this method returns when it has read as many bytes as are currently available on the socket, up to the requested number of bytes, or an error occurs.
If the READ( ) method succeeds, the variable buffer contains the data which is read from the socket. It is possible that the socket will not contain the specified number of bytes of data which were requested. The BYTES-READ attribute can be used to determine the number of bytes read from the socket.

This method expects buffer to identify a MEMPTR variable which already has a region of memory associated with it. The developer must call the SET-SIZE statement to allocate memory and associate it with a MEMPTR variable. It is the responsibility of the developer to free this memory, also via the SET-SIZE statement. The READ method will fail if the size of buffer is less than bytes-to-read.

READ-FILE( ) method

Clears an editor widget, reads the contents of a specified text file into the widget, and sets the widget’s MODIFIED attribute to FALSE.

**Return type:** LOGICAL

**Applies to:** EDITOR widget

**Syntax**

```
READ-FILE( filename )
```

*filename*

A character-string expression equal to the full or relative pathname of a file. If you specify a relative pathname, the READ-FILE( ) method searches PROPATH to find the file.

If the operation is successful, the method returns TRUE.

In Windows, this method interprets a carriage return character followed by a line feed character as a text line terminator. In all other interfaces, this method interprets a carriage return character as a text line terminator.

READ-ONLY attribute

Indicates whether an object is write-protected.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (browse and column), Buffer-field object handle, EDITOR widget, FILL-IN widget, MENU-ITEM widget

If the READ-ONLY attribute of an editor or fill-in widget is TRUE, the widget cannot be enabled for input and its screen value cannot be changed from the user interface.

If the READ-ONLY attribute for a browse widget is TRUE, you cannot update editable cells. If it is set to false, then the ability to edit cells is restored. This functionality only applies to columns that have been enabled in the DEFINE BROWSE statement.

For combo-box browse columns, this attribute is read-only and always returns FALSE.
If the READ-ONLY attribute of a menu item is TRUE, the menu item cannot be chosen. You can set this attribute for a menu item only before the widget is realized.

The READ-ONLY attribute has no effect on the appearance of a widget. If an editor or menu item is insensitive, it is grayed out in some environments. Use the READ-ONLY attribute instead to make the widget insensitive without being grayed out.

READ-JS0N( ) method

Reads a JSON string into a ProDataSet, a temp-table, or a temp-table buffer object.

**Return type:** LOGICAL

**Applies to:** Buffer object handle, ProDataSet object handle, Temp-table object handle

**Syntax**

```
READ-JS0N ( source-type, { file | memptr | handle | longchar } [, read-mode ] )
```

**source-type**

A CHARACTER expression that specifies the source JSON string type. Valid values are “FILE”, “MEMPTR”, “HANDLE”, and “LONGCHAR”.

**file**

A CHARACTER expression that specifies the name of a file. You can specify an absolute pathname or one relative to the current working directory. The AVM verifies that the file exists and is accessible.

**memptr**

A MEMPTR variable that contains the JSON string in memory. The size of the MEMPTR variable must match the size of the JSON string.

**handle**

A HANDLE variable that specifies the WEB-CONTEXT system handle.

This method reads a JSON string from the WebSpeed Transaction Server. The method verifies that the JSON string was posted to the WebSpeed Transaction Server by checking that the handle’s IS-JSON attribute is YES. The method also verifies that ABL is running in a WebSpeed environment.

**longchar**

A LONGCHAR variable that contains the JSON string in memory.

**read-mode**

A CHARACTER expression that specifies the mode in which this method reads data from the JSON string into a temp-table or a ProDataSet member buffer. The expression must evaluate to “APPEND”, “EMPTY”, “MERGE”, or “REPLACE”. The default value is "MERGE".
Table 95 lists the READ-JSON( ) method modes for reading data.

<table>
<thead>
<tr>
<th>When the mode is . . .</th>
<th>The READ-JSON( ) method . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPEND</td>
<td>Reads data from the JSON string into the ProDataSet or temp-table object by adding new records to the existing records, without performing any record comparisons. If a record from the JSON string exists in the object (that is, it results in a duplicate unique key conflict), the method generates an error message and returns FALSE.</td>
</tr>
<tr>
<td>EMPTY</td>
<td>Empties the contents of the ProDataSet or temp-table object before reading in data from the JSON string.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Reads data from the JSON string into the ProDataSet or temp-table object by merging new records with existing records in the table. If a record from the JSON string exists in the object (that is, it results in a duplicate unique key conflict), the method does not replace the existing record. If the record from the JSON string does not exist in the object, the method creates a new record.</td>
</tr>
<tr>
<td>REPLACE</td>
<td>Reads data from the JSON string into the ProDataSet or temp-table object by merging new records with existing records in the table. If the record from the JSON string exists in the object (that is, it results in a duplicate unique key conflict), the method replaces the existing record with the new record. If the record from the JSON string does not exist in the object, the method creates a new record.</td>
</tr>
</tbody>
</table>

For a dynamic ProDataSet or temp-table that is in the CLEAR state, the AVM infers the object’s schema from the data in the JSON value. If a dynamic temp-table is not in the PREPARED or CLEAR state, the method generates an error and returns FALSE. For more information about inferring schema from a JSON string, see *OpenEdge Development: Working with JSON*.

For a static ProDataSet or temp-table, the serialize name or object name must match the name found in the JSON string. If the names do not match, the AVM generates an error message and the method returns FALSE. The AVM ignores any columns in the JSON string that do not map to temp-table columns. If you use the SERIALIZE-NAME option in the DEFINE DATASET or DEFINE TEMP-TABLE statement, the AVM uses that name for matching, rather than the ABL object name.

You cannot read a JSON string into a database buffer.

The following code example creates a dynamic ProDataSet object from an empty ProDataSet handle, creates the objects schema by inference from the specified JSON string, and populates the temp-tables with records from the specified JSON document:
The following code example creates a dynamic temp-table object from an empty temp-table handle, creates the object's schema by inference from the specified JSON string, and populates the temp-table with records from the same string:

```prolog
DEFINE VARIABLE cSourceType AS CHARACTER NO-UNDO.
DEFINE VARIABLE cReadMode AS CHARACTER NO-UNDO.
DEFINE VARIABLE cFile AS CHARACTER NO-UNDO.
DEFINE VARIABLE lRetOK AS LOGICAL NO-UNDO.
DEFINE VARIABLE hDSet AS HANDLE NO-UNDO.

CREATE DATASET hDSet.
ASSIGN
  cSourceType = "file"
  cFile    = "dset.json"
  cReadMode = "empty"
  lRetOK = hDSet:READ-JSON(cSourceType, cFile, cReadMode).
```

The following code example creates a dynamic temp-table object from an empty temp-table handle, creates the object's schema by inference from the specified JSON string, and populates the temp-table with records from the same string:

```
DEFINE VARIABLE cSourceType AS CHARACTER NO-UNDO.
DEFINE VARIABLE cReadMode AS CHARACTER NO-UNDO.
DEFINE VARIABLE cFile AS CHARACTER NO-UNDO.
DEFINE VARIABLE lRetOK AS LOGICAL NO-UNDO.
DEFINE VARIABLE htcust AS HANDLE NO-UNDO.

CREATE TEMP-TABLE htcust.
ASSIGN
  cSourceType = "file"
  cFile    = "ttcust.json"
  cReadMode = "empty"
  lRetOK = htcust:READ-JSON(cSourceType, cFile, cReadMode).
```

See also: IS-JSON attribute, WEB-CONTEXT system handle, WRITE-JSON( ) method

**READ-XML( ) method**

Reads an XML document into a ProDataSet, temp-table, or temp-table buffer object. You can read data, schema, or both.

**Return type:** LOGICAL

**Applies to:** Buffer object handle, ProDataSet object handle, Temp-table object handle

**Syntax**

```prolog
READ-XML( source-type, { file | memptr | handle | longchar }, read-mode, schema-location, override-default-mapping [, field-type-mapping [, verify-schema-mode ] ] )
```

**source-type**

A CHARACTER expression that specifies the source XML document type. Valid values are “FILE”, “MEMPTR”, “HANDLE”, and “LONGCHAR”.

1651
**file**

A CHARACTER expression that specifies the name of a file. You can specify an absolute pathname, a relative pathname (based on the current working directory), or a URL pathname. Valid URL protocols include FILE and HTTP (the HTTPS protocol is not supported). The AVM verifies that the file exists and is accessible.

**memptr**

A MEMPTR variable that contains the XML document text in memory. The size of the MEMPTR variable must match the size of the XML document text.

**handle**

A WEB-CONTEXT system handle, X-document object handle, or X-noderef object handle.

For a WEB-CONTEXT system handle, the READ-XML( ) method reads an XML document from the WebSpeed transaction server. The method verifies that the XML document was posted to the WebSpeed transaction server (that is, the value of the IS-XML attribute for the handle is YES), and that ABL is running in a WebSpeed environment.

**longchar**

A LONGCHAR variable that contains the XML document text in memory.

**read-mode**

A CHARACTER expression that specifies the mode in which the READ-XML( ) method reads data from the XML document into a temp-table or ProDataSet member buffer. The expression must evaluate to “APPEND”, “EMPTY”, “MERGE”, or “REPLACE”. The default value is “MERGE”.

Table 96 lists the READ-XML( ) method modes for reading data.

### Table 96: READ-XML( ) method read modes (1 of 2)

<table>
<thead>
<tr>
<th>When the mode is...</th>
<th>The READ-XML( ) method...</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPEND</td>
<td>Reads data from the XML document into the ProDataSet or temp-table object by adding new records to the existing records, without performing any record comparisons. If a record from the XML document exists in the object (that is, it results in a duplicate unique key conflict), the method generates an error message and returns FALSE.</td>
</tr>
<tr>
<td>EMPTY</td>
<td>Empties the contents of the ProDataSet or temp-table object before reading in data from the XML document.</td>
</tr>
</tbody>
</table>
schema-location

A CHARACTER expression that specifies the name of an external XML Schema file to use in creating or verifying the object’s schema when reading in the XML document. You can specify an absolute pathname, a relative pathname (based on the current working directory), or a URL pathname. Valid URL protocols include FILE and HTTP (the HTTPS protocol is not supported). The AVM verifies that the file exists and is accessible. When specified, the AVM ignores any schema defined or referenced in the source XML Document.

If you specify the empty string (""") or the Unknown value (?), the AVM creates or verifies the object’s schema using any XML Schema defined or referenced in the source XML document.

override-default-mapping

A LOGICAL expression where TRUE directs the AVM to override the default mapping between XML Schema string and binary data types and ABL data types when creating an ABL temp-table schema from an XML Schema. The default value is FALSE.

The XML Schema string data type maps to the ABL CHARACTER data type by default, and the XML Schema base64Binary and hexBinary data types map to the ABL RAW data type by default. If you specify TRUE, the READ-XML() method creates a temp-table schema with CLOB and BLOB fields instead of CHARACTER and RAW fields.

If you specify the Unknown value (?), the method uses the default value of FALSE.

field-type-mapping

An optional CHARACTER expression that evaluates to a comma-separated list of field name, data type pairs using the following syntax:

Syntax

\( field-name-1, data-type-1 [, field-name-n, data-type-n ] ... \)
This option allows you to specify the ABL data type for a specific field from the XML Schema.

**field-name**

A CHARACTER expression that evaluates to the name of the specified field. For a ProDataSet object, you must qualify the field name with the buffer name from the XML Schema. That is, `buffer-name.field-name`.

**data-type**

A CHARACTER expression that evaluates to the data type of the specified field. The data type must be a valid ABL data type, and it must be compatible with the XML Schema type based on the ABL XML data type mapping rules. For example, any XML Schema type can be mapped to an ABL CHAR or CLOB, but an XML Schema dateTime can be mapped only to an ABL DATE, DATETIME or DATETIME-TZ.

If you specify the Unknown value (?), the method uses the default data type mapping. For more information about the ABL XML data type mapping rules, see *OpenEdge Development: Working with XML*.

**verify-schema-mode**

An optional CHARACTER expression that specifies the mode in which the READ-XML( ) method verifies any XML Schema against existing ABL schema. The expression must evaluate to “IGNORE”, “LOOSE”, or “STRICT”. The default value is “LOOSE”.

**Note:** For a dynamic temp-table or ProDataSet member buffer that does not have ABL schema (that is, the object is in the CLEAR state), this option is ignored.

Table 97 lists the READ-XML( ) method schema verification modes.

**Table 97: READ-XML( ) method schema verification modes (1 of 3)**

<table>
<thead>
<tr>
<th>When the mode is . . .</th>
<th>The READ-XML( ) method . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGNORE</td>
<td>Ignores any XML Schema specified in <code>schema-location</code>, or defined in the XML Document.</td>
</tr>
</tbody>
</table>
Table 97: READ-XML() method schema verification modes

<table>
<thead>
<tr>
<th>When the mode is ...</th>
<th>The READ-XML() method ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOOSE</td>
<td>For temp-table objects:</td>
</tr>
<tr>
<td></td>
<td>• Matches temp-table columns by name. The data type and extent of the column in the XML Schema must match those for the matching column in the temp-table. Other field attributes in the XML Schema are ignored.</td>
</tr>
<tr>
<td></td>
<td>• The XML Schema may be a subset or superset of the temp-table schema. Any columns that are in the XML Schema but not in the temp-table are ignored. Any columns that are in the temp-table, but not in the XML Schema, are ignored.</td>
</tr>
<tr>
<td></td>
<td>For ProDataSet objects:</td>
</tr>
<tr>
<td></td>
<td>• Matches temp-tables and columns by name. The data type and extent of the column in the XML Schema must match those for the matching column in the temp-table. Other field attributes in the XML Schema are ignored.</td>
</tr>
<tr>
<td></td>
<td>• Data relationships are matched by parent buffer and child buffer names. For every data relationship in the XML Schema that matches a data-relation in the ProDataSet, the field mapping between the parent and child buffers must match.</td>
</tr>
<tr>
<td></td>
<td>• The XML Schema may be a subset or superset of the ProDataSet schema. Any temp-tables, columns, or data-relations that are in the ProDataSet, but not in the XML Schema, are ignored.</td>
</tr>
<tr>
<td></td>
<td>• For a dynamic ProDataSet object, the method adds temp-tables and data-relations to the object when the temp-tables and data-relations are defined in the XML Schema, but are not members of the ProDataSet. Fields are not added to existing temp-tables. For a static ProDataSet object, any temp-tables or data-relations that are in the XML Schema, but not in the ProDataSet, are ignored.</td>
</tr>
</tbody>
</table>
If the XML Schema verification fails, the method generates an error message indicating the XML Schema element that caused the failure and returns FALSE.

If the ProDataSet or temp-table object does not have a schema (that is, the object is dynamic and in the CLEAR state), the AVM creates the schema from either the XML Schema file specified in `schema-location`, or the XML Schema defined or referenced in the XML document. If a dynamic temp-table is not in the PREPARED or CLEAR state, the method generates an error and returns FALSE.

ABL has a pair of attributes with overlapping purposes in how the AVM reads XML data, `SERIALIZE-NAME` and `XML-NODE-NAME`. Refer to the attribute entries for a full description of their interaction.

If the ProDataSet or temp-table object already has a schema (that is, the object is static, or the temp-tables are in the PREPARED state), the AVM verifies any XML Schema specified by `schema-location`, or defined or referenced in the XML document, against the object’s schema, unless the `verify-schema-mode` is “IGNORE”.

If the AVM cannot identify any XML Schema for the ProDataSet or temp-table object, (that is, `schema-location` is the empty string (“”) or the Unknown value (?) and the XML document does not define or reference a schema, the AVM infers the schema from the data in the XML document.
For more information about creating schema from XML Schema, verifying XML Schema, or inferring schema from XML document text, see *OpenEdge Development: Working with XML*.

The XML document can also contain before-image table data associated with a ProDataSet object. If the XML document data is in the Microsoft DiffGram format, the method reads the before-image data as well. In this case, if the ProDataSet or temp-table object is static and it does not have a before-image table defined, the method generates an error and returns FALSE. If the ProDataSet or temp-table object is dynamic, the method creates the before-image table automatically.

**Note:** During the read operation, the AVM does not respond to ProDataSet events, and it does not track changes to the data in the ProDataSet or temp-table object (that is, it does not update the before-image tables) unless the XML document data is in the Microsoft DiffGram format.

You cannot read an XML document into a database buffer.

**Note:** When executing the READ-XML( ) method on a temp-table or ProDataSet, and the default buffer of one of the contained temp-tables is available, there is no guarantee as to the state of that buffer after the method finishes executing. The record buffer may not be available. If default buffer availability is an issue, it is suggested that a named buffer be used with this method. A named buffer can be created with the DEFINE BUFFER statement.

The following code example creates a dynamic ProDataSet object from an empty ProDataSet handle, creates the object’s schema from the specified XML Schema file, and populates the temp-tables with records from the specified XML document:

```sql
DEFINE VARIABLE cSourceType AS CHARACTER NO-UNDO.
DEFINE VARIABLE cReadMode AS CHARACTER NO-UNDO.
DEFINE VARIABLE lOverrideDefaultMapping AS LOGICAL NO-UNDO.
DEFINE VARIABLE cFile AS CHARACTER NO-UNDO.
DEFINE VARIABLE cSchemaLocation AS CHARACTER NO-UNDO.
DEFINE VARIABLE cFieldTypeMapping AS CHARACTER NO-UNDO.
DEFINE VARIABLE cVerifySchemaMode AS CHARACTER NO-UNDO.
DEFINE VARIABLE lRetOK AS LOGICAL NO-UNDO.
DEFINE VARIABLE hDSet AS HANDLE NO-UNDO.
CREATE DATASET hDSet.
ASSIGN
cSourceType = "file"
cFile = "dset.xml"
cReadMode = "empty"
cSchemaLocation = "cust-ord-inv.xsd"
lOverrideDefaultMapping = ?
cFieldTypeMapping = ?
cVerifySchemaMode = ?.
lRetOK = hDSet:READ-XML(cSourceType, cFile, cReadMode, cSchemaLocation, lOverrideDefaultMapping, cFieldTypeMapping, cVerifySchemaMode).
```

The following code example creates a dynamic temp-table object from an empty temp-table handle, creates the object’s schema from the specified XML Schema file, and populates the temp-table with records from the specified XML document:
**READ-XMLSCHEMA( ) method**

**README-XMLSCHEMA( ) method**

Reads XML Schema from an XML document and uses that schema to either create a schema for a ProDataSet or temp-table object, or verify existing schema in a ProDataSet, temp-table, or temp-table buffer object. The XML document must be an XML Schema written in the XML Schema Definition (XSD) language in the 2001 XML Schema namespace (http://www.w3.org/2001/XMLSchema).

**Return type:** LOGICAL

**Applies to:** Buffer object handle, ProDataSet object handle, Temp-table object handle

**Syntax**

```plaintext
READ-XMLSCHEMA( source-type, { file | memptr | handle | longchar }, { override-default-mapping, field-type-mapping, verify-schema-mode } )
```

**source-type**

A CHARACTER expression that specifies the source XML document type. Valid values are: “FILE”, “MEMPTR”, “HANDLE”, and “LONGCHAR”.

**file**

A CHARACTER expression that specifies the name of an XML Schema file. You can specify an absolute pathname, a relative pathname (based on the current working directory), or a URL pathname. Valid URL protocols include FILE and HTTP (the HTTPS protocol is not supported). The AVM verifies that the file exists and is accessible.
**memptr**

A MEMPTR variable that contains the XML Schema document text. The size of the MEMPTR variable must match the size of the XML document text.

**handle**

A WEB-CONTEXT system handle, X-document object handle, or X-noderef object handle.

For a WEB-CONTEXT system handle, the READ-XMLSCHEMA( ) method reads an XML Schema document from the WebSpeed transaction server. The method verifies that the XML document was posted to the WebSpeed transaction server (that is, the value of the IS-XML attribute for the handle is YES), and that ABL is running in a WebSpeed environment.

**longchar**

A LONGCHAR variable that contains the XML Schema document text in memory.

**override-default-mapping**

A LOGICAL expression where TRUE directs the AVM to override the default mapping between XML Schema string and binary data types and ABL data types when creating an ABL temp-table schema from an XML Schema. The default value is FALSE.

The XML Schema string data type maps to the ABL CHARACTER data type by default, and the XML Schema base64Binary and hexBinary data types map to the ABL RAW data type by default. If you specify TRUE, the READ-XMLSCHEMA( ) method creates a temp-table schema with CLOB and BLOB fields instead of CHARACTER and RAW fields.

If you specify the Unknown value (?), the method uses the default value of FALSE.

**field-type-mapping**

An optional CHARACTER expression that evaluates to a comma-separated list of field name, data type pairs using the following syntax:

**Syntax**

```
field-name-1, data-type-1 [ , field-name-n, data-type-n ] . . .
```

This option allows you to specify the ABL data type for a specific field from the XML Schema.

**field-name**

A CHARACTER expression that evaluates to the name of the specified field. For a ProDataSet object, you must qualify the field name with the buffer name from the XML Schema. That is, `buffer-name.field-name`.

**data-type**

A CHARACTER expression that evaluates to the data type of the specified field. The data type must be a valid ABL data type, and it must be compatible with the XML Schema type based on the ABL XML data type mapping rules. For example, any
XML Schema type can be mapped to an ABL CHAR or CLOB, but an XML Schema dateTime can be mapped only to an ABL DATE, DATETIME or DATETIME-TZ.

If you specify the Unknown value (?), the method uses the default data type. For more information about the ABL XML data type mapping rules, see *OpenEdge Development: Working with XML*.

**verify-schema-mode**

An optional CHARACTER expression that specifies the mode in which the READ-XMLSCHEMA( ) method verifies any XML Schema against existing ABL schema. The expression must evaluate to “LOOSE” or “STRICT”. The default value is “LOOSE”.

**Note:** For a dynamic temp-table or ProDataSet member buffer that does not have ABL schema (that is, the object is in the CLEAR state), this option is ignored.

Table 98 lists the READ-XMLSCHEMA( ) method schema verification modes.

<table>
<thead>
<tr>
<th>When the mode is . . .</th>
<th>The READ-XMLSCHEMA( ) method . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOOSE</td>
<td>For temp-table objects:</td>
</tr>
<tr>
<td></td>
<td>• Matches temp-table columns by name. The data type and extent of the column in the XML Schema must match those for the matching column in the temp-table. Other field attributes in the XML Schema are ignored.</td>
</tr>
<tr>
<td></td>
<td>• The XML Schema may be a subset or superset of the temp-table schema. Any columns that are in the XML Schema but not in the temp-table are ignored. Any columns that are in the temp-table, but not in the XML Schema, are ignored.</td>
</tr>
<tr>
<td></td>
<td>For ProDataSet objects:</td>
</tr>
<tr>
<td></td>
<td>• Matches temp-tables and columns by name. The data type and extent of the column in the XML Schema must match those for the matching column in the temp-table. Other field attributes in the XML Schema are ignored.</td>
</tr>
<tr>
<td></td>
<td>• Data relationships are matched by parent buffer and child buffer names. For every data relationship in the XML Schema that matches a data-relation in the ProDataSet, the field mapping between the parent and child buffers must match.</td>
</tr>
<tr>
<td></td>
<td>• The XML Schema may be a subset or superset of the ProDataSet schema. Any temp-tables, columns, or data-relations that are in the ProDataSet, but not in the XML Schema, are ignored.</td>
</tr>
<tr>
<td></td>
<td>• For a dynamic ProDataSet object, the method adds temp-tables and data-relations to the object when the temp-tables and data-relations are defined in the XML Schema, but are not members of the ProDataSet. Fields are not added to existing temp-tables. For a static ProDataSet object, any temp-tables or data-relations that are in the XML Schema, but not in the ProDataSet, are ignored.</td>
</tr>
</tbody>
</table>
If you specify the Unknown value (?), the method uses the default value of LOOSE.

If the XML Schema verification fails, the method generates an error message indicating the XML Schema element that caused the failure and returns FALSE.

If the ProDataSet or temp-table object does not have a schema (that is, the object is dynamic and in the CLEAR state), the AVM creates the schema from the XML Schema defined in the XML Schema document.

If the ProDataSet or temp-table object already has a schema (that is, the object is static, or the temp-tables are in the PREPARED state), the AVM verifies the XML Schema defined in the XML Schema document against the object’s schema.

If a dynamic temp-table is not in the PREPARED or CLEAR state, the method generates an error and returns FALSE.

For more information about creating schema from XML Schema or verifying XML Schema, see *OpenEdge Development: Working with XML*.

You cannot create schema for a temp-table buffer or a database buffer.

The following code example verifies the schema in a static ProDataSet object, in STRICT mode, using the schema defined in the specified XML Schema file:
The following code example creates a dynamic temp-table object, creates the object’s schema from the specified XML Schema file, and overrides the default data type mapping of one field:

```
DEFINE VARIABLE lRetOK AS LOGICAL NO-UNDO.
DEFINE VARIABLE cSourceType AS CHARACTER NO-UNDO.
DEFINE VARIABLE cFile AS CHARACTER NO-UNDO.
DEFINE VARIABLE lOverrideDefaultMapping AS LOGICAL NO-UNDO.
DEFINE VARIABLE cFieldTypeMapping AS CHARACTER NO-UNDO.
DEFINE VARIABLE cVerifySchemaMode AS CHARACTER NO-UNDO.

DEFINE TEMP-TABLE ttCustomer LIKE Customer NO-UNDO.
DEFINE TEMP-TABLE ttOrder LIKE Order NO-UNDO.
DEFINE TEMP-TABLE ttInvoice LIKE Invoice NO-UNDO.

DEFINE DATASET DSET FOR ttCustomer, ttOrder, ttInvoice
  DATA-RELATION CustOrd FOR ttCustomer,
      ttOrd RELATION-FIELDS(CustNum,CustNum) NESTED
  DATA-RELATION OrdInv FOR ttOrder,
      ttInv RELATION-FIELDS(OrderNum,OrderNum) NESTED.

ASSIGN
cSourceType = "file"
cFile = "cust-ord-inv.xsd"
lOverrideDefaultMapping = FALSE

cFieldTypeMapping = ?
cVerifySchemaMode = "strict"

lRetOK = DSET DSET:READ-XMLSCHEMA (cSourceType, cFile,
  lOverrideDefaultMapping, cFieldTypeMapping, cVerifySchemaMode).
```

See also: IS-XML attribute, READ-XML() method, WEB-CONTEXT system handle, WRITE-XML() method, WRITE-XMLSCHEMA() method, X-document object handle, X-noderef object handle

**RECID attribute**

The unique internal identifier of the database record currently associated with the buffer.
RECORD-LENGTH attribute

The length, in bytes, of the record associated with a buffer.

| Data type: | LOGICAL |
| Access:    | Readable |
| Applies to:| Buffer object handle |

REFRESH( ) method

Forces the AVM to refresh the display of the current rows in a browse.

| Return type: | LOGICAL |
| Applies to:  | BROWSE widget |

Syntax

```
REFRESH ( )
```

If the AVM successfully refreshes the widget, the method returns the value TRUE.

REFRESHABLE attribute

Indicates whether the rows that appear in a browse are refreshed when an application opens or repositions a query.
Note: When an application opens a query or repositions it multiple times, and refreshes the viewport each time, the display might flash, which is distracting. You can suppress the refreshing, and so reduce the flashing, by setting REFRESHABLE to FALSE.

Data type: LOGICAL  
Access: Readable/Writeable  
Applies to: BROWSE widget

If REFRESHABLE is FALSE, when an application opens or repositions a query, the viewport is not refreshed. REFRESHABLE’s default value is TRUE.

REFRESH-AUDIT-POLICY( ) method

Notifies the specified audit-enabled database that its audit policy tables have changed, which causes the database to refresh its current run-time audit policy settings cache before performing any more database operations.

Return type: LOGICAL  
Applies to: AUDIT-POLICY system handle

Syntax

REFRESH-AUDIT-POLICY( integer-expression | logical-name | alias )

integer-expression

The sequence number of the connected database that needs to refresh its audit policy settings cache. For example, REFRESH-AUDIT-POLICY(1) notifies the first database, REFRESH-AUDIT-POLICY(2) notifies the second database, and so on. If you specify a sequence number that does not correspond to a connected database, the AVM generates a run-time error.

logical-name or alias

The logical name or alias of the connected database that needs to refresh its audit policy settings cache. These forms require a quoted character string or a character expression. If you specify a logical name or alias that does not correspond to a connected database, the AVM generates a run-time error.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

For information about audit-enabling a database, or creating and activating an audit policy for a database, see *OpenEdge Getting Started: Core Business Services*. 
REGIESTER-DOMAIN( ) method

Registers an authentication domain in the application’s trusted authentication domain registry. The AVM uses this registry to validate Client-principal objects during the session. After you have registered all authentication domains for a session, you must restrict the registration of additional domains by calling the LOCK-REGISTRATION( ) method.

Caution: Use caution when registering authentication domains in the application’s trusted authentication domain registry using the REGISTER-DOMAIN( ) and LOCK-REGISTRATION( ) methods. You can introduce the risk for a security breach by allowing the registration of rogue domains between registering your domains and locking the registry. Consider using the LOAD-DOMAINS( ) method, which loads authentication domain registry information directly from an OpenEdge database and then automatically locks the registry.

Return type: LOGICAL
Applies to: SECURITY-POLICY system handle

Syntax

REGISTER-DOMAIN( domain-name, domain-key [, domain-description [, domain-type ] ] )

*domain-name*

A character expression that specifies the name of this authentication domain.

*domain-key*

A character expression that specifies the key to use when validating a Client-principal object created in this domain. The AVM converts this key to UTF-8 before using it, which ensures a consistent value regardless of code page settings.

*domain-description*

An optional character expression that specifies a description for this domain.

*domain-type*

An optional character expression that specifies an application-defined domain type.

You must call the LOCK-REGISTRATION( ) method before you can use the trusted authentication domain registry to validate Client-principal objects for the application.

If you do not register at least one authentication domain in the trusted authentication domain registry before calling this method, this method returns TRUE. However, any attempt to seal a Client-principal object will generate a run-time error.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

The following code fragment illustrates how to use the REGISTER-DOMAIN( ) method:
REJECT-CHANGES( ) method

Rejects changes to the data in one temp-table or all temp-tables in a ProDataSet object.

Return type: LOGICAL
Applies to: Buffer object handle, ProDataSet object handle

Syntax

handled:REJECT-CHANGES( )

handled

A handle to the temp-table buffer or the ProDataSet object.

When you reject changes on a ProDataSet object handle, the AVM uses the before-image table to back out changes from the after-image table, and empties the before-image table for each table in the ProDataSet.

When you reject changes for a Buffer object handle, the AVM uses the before-image table to back out changes from the after-image table, and empties the before-image table for that one table.

As the AVM rejects changes, it sets the BEFORE-ROWID attribute of every row in the after-image table to the Unknown value (?), and sets the ROW-STATE of every row in the after-image table to ROW-UNMODIFIED (0).

REJECT-ROW-CHANGES( ) method

Rejects changes to the data in one row of a ProDataSet temp-table.

Return type: LOGICAL
Applies to: Buffer object handle

Syntax

handled:REJECT-ROW-CHANGES( )

handled

A handle to the temp-table buffer or the ProDataSet object.
**handle**

A handle to a before-image temp-table buffer.

When you reject changes for a temp-table row, the AVM uses the before-image table row to back out changes in the after-image table row. The AVM also sets the BEFORE-ROWID attribute of the row in the after-image table to the Unknown value (?), sets the ROW-STATE of the row in the after-image table to ROW-UNMODIFIED (0), and removes the before-image table row.

---

**REJECTED attribute**

Set this attribute to indicate whether a change to the data in a ProDataSet object, a temp-table buffer, or a temp-table row is rejected.

| Data type: | LOGICAL |
| Access:    | Readable/Writeable |
| Applies to: | Buffer object handle, ProDataSet object handle, Temp-table object handle |

The REJECTED attribute corresponds to the REJECTED function.

The MERGE-CHANGES( ) method and MERGE-ROW-CHANGES( ) method use this attribute to determine whether to reject a changed row during a merge operation.

This attribute is marshalled between the client and the AppServer.

---

**RELATION-FIELDS attribute**

Returns a comma-separated list of parent-field, child-field pairs describing the relationship between parent and child buffers as specified in the data-relation object definition.

| Data type: | CHARACTER |
| Access:    | Readable |
| Applies to: | Data-relation object handle |

Returns this comma-separated list using the following syntax:

**Syntax**

```plaintext
parent-field1, child-field1 [, parent-fieldn, child-fieldn ] ... 
```

You can use the value of this attribute in writing code that uses or extends this list of join fields without having to parse the value of the WHERE-STRING attribute, which in the default case provides essentially the same information but not necessarily in an ideal form for analyzing the relation.
RELATIONS-ACTIVE attribute

Indicates whether all data-relation objects in a ProDataSet object are active or inactive. Set to TRUE to activate all data-relation objects. Set to FALSE to deactivate all data-relation objects. All data-relation objects in a ProDataSet object are active by default.

Alternatively, you can activate or deactivate an individual data-relation object in a ProDataSet object by setting the ACTIVE attribute on the Data-relation object handle.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** ProDataSet object handle

Deactivate all data-relations in a ProDataSet object when you want a FILL operation to load data into each ProDataSet member buffer using the individual buffer’s query (instead of recursively loading parent and child buffers as defined by the data-relations). Likewise, you can reactivate all data-relations in a ProDataSet object after completing a FILL operation to use the data-relations for traversing the data after the data is loaded.

When the AVM encounters an inactive relation (or the last child buffer in the relation tree), during a FILL operation on a ProDataSet buffer object handle, the AVM does not fill the child buffers of that relation. When the AVM encounters an inactive relation during a FILL operation on a ProDataSet object handle, it treats the first child buffer of the inactive relation as a top-level table (including all records from its data source) and fills each child buffer based on the data relation’s query. If you do not want the AVM to treat the first child buffer of the inactive relation as a top-level table, set the FILL-MODE of that buffer to NO-FILL. The AVM does not fill any of the child buffers.

If the AVM encounters an inactive relation while navigating a ProDataSet object, it does not prepare or open a dynamic query for the child table, even if there is a browse associated with the relation’s query. If you want to access the child temp-table, you must do so through a separate query, a FOR EACH statement, or some other standard ABL construct in your application code.

When you reactivate data-relations, the AVM does not automatically resynchronize the hierarchy of queries on buffers below the newly active relation. If you want to resynchronize the related buffers, use the SYNCHRONIZE() method on the parent buffer.

REMOTE attribute

Indicates whether the specified procedure is running at the top level of an AppServer session as the result of a remote procedure call from a client application, or whether the current ABL session is an AppServer session. Returns FALSE for a Web service procedure.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** Procedure object handle, SESSION system handle

For any procedure handle, REMOTE is TRUE if:

- The specified procedure is running locally at the top level of the current session.
The current session is an AppServer session.

The procedure is running directly as the result of a remote procedure call from a client application.

Otherwise, REMOTE is FALSE. Thus, if the procedure handle is a proxy handle (PROXY attribute set to TRUE) or the specified procedure is running as the direct result of a call from any other procedure running in the current session context, REMOTE is FALSE.

For the SESSION handle, REMOTE is TRUE if the session runs in the context of an AppServer, and FALSE if the session runs in the context of an ABL client.

For more information on the AppServer, see *OpenEdge Application Server: Developing AppServer Applications*.

### REMOTE-HOST attribute

Indicates the IP (Internet Protocol) address of the machine with which the socket object is communicating.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** Socket object handle

When a server and client successfully establish a connection, both the server and client have a socket object that identifies this connection. On the client, this attribute returns the IP address of the server, and on the server, this attribute returns the IP address of the client. If the CONNECT( ) method fails or has not been called, this attribute returns the Unknown value (??).

**See also:** DB-REMOTE-HOST function

### REMOTE-PORT attribute

Indicates the port number of the socket.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** Socket object handle

When a server and client successfully establish a connection, both the server and client have a socket object that identifies this connection. On the client, this attribute returns the port number used on the server machine for this socket connection. On the server, this attribute returns the port number used on the client machine for this socket connection. If the CONNECT failed, this attribute returns the Unknown value (??).
REMOVE-ATTRIBUTE( ) method

Removes the specified attribute of an element. If the removed attribute has a default value (specified by the document’s DTD) it is set to its default value.

**Return type:** LOGICAL

**Applies to:** SAX-attributes object handle, X-noderef object handle

**Syntax**

```
REMOVE-ATTRIBUTE( { attribute-name | index } [, namespaceURI ] )
```

**attribute-name**

A CHARACTER expression evaluating to the fully qualified or unqualified name of the attribute.

**index**

For SAX-attributes object handle only. An integer expression evaluating to the position of the attribute in the attribute list. The first attribute has an index of 1. When using `index`, `namespaceURI` must be the Unknown value (\(?\)), an empty string, or not supplied. Otherwise, an invalid argument error will be raised.

**namespaceURI**

A CHARACTER expression evaluating to:

- The URI of the attribute
- A zero-length string
- The Unknown value (\(?\)) if the attribute doesn’t contain a namespace

Call this method to remove an attribute from a SAX-attributes object or an X-noderef object. For example, if an XML element obtained from the SAX-reader object has a larger set of attributes than that required by the document being written by the SAX-writer, use this method to find and remove the extra attributes.

The index values of attributes left in the list is then updated to reflect the removed attribute. The SAX-attributes NUM-ITEMS attribute value will also be decremented to reflect the removed attribute.

If the method fails to find a match, because the name is not found or the index position is invalid, then the method will not remove an attribute and return FALSE.

If using an `attribute-name`, the method removes the first match it finds in the list.

The following are examples for a SAX-attributes object:
The following X-noderef object example removes the attribute “Id”, or resets the attribute “Id” to its default value, for the XML node represented by hNoderef:

```plaintext
hNoderef:REMOVE-ATTRIBUTE("Id").
```

**REMOVE-CHILD( ) method**

Unlinks the node and its sub-tree from the XML document. The XML object is not deleted, only disconnected from the structure.

**Return type:** LOGICAL

**Applies to:** X-document object handle, X-noderef object handle

**Syntax**

```plaintext
REMOVE-CHILD( x-node-handle )
```

*x-node-handle*

The handle that represents the node to remove from the tree.

The following code fragment gets a reference to the fourth node on the document root, and removes it. hNoderef is still available for use after the remove, but is unlinked from hRoot:

```plaintext
CREATE X-NODEREF hNoderef.
... hRoot:GET-CHILD(hNoderef,4).
   hRoot:REMOVE-CHILD(hNodeRef).
... 
```

**REMOVE-EVENTS-PROCEDURE( ) method**

(Windows only; Graphical interfaces only)

Removes an external procedure from the list that the AVM searches for event procedures to handle an ActiveX control event.
**REMOVE-SUPER-PROCEDURE( ) method**

Dissociates a super procedure file from a procedure file or from the current ABL session. Returns FALSE for a Web service procedure.

**Note:** Dissociating a super procedure file from the current ABL session does not automatically dissociate the super procedure file from procedure files within the session.

**Return type:** LOGICAL  
**Applies to:** Procedure object handle, SESSION system handle  

**Syntax**

```
REMOVE-SUPER-PROCEDURE ( super-proc-hdl )
```

**super-proc-hdl**  
A handle to the super procedure.

**Note:** If `super-proc-hdl` is not a valid procedure handle or is not currently a super procedure of the local procedure or of the current ABL session, the AVM does not report a run-time error.

REMOVE-SUPER-PROCEDURE returns FALSE if `super-proc-hdl` is not a valid handle. Otherwise, it returns TRUE.

The following code fragment dissociates a super procedure from the current procedure:

```
THIS-PROCEDURE:REMOVE-SUPER-PROCEDURE(my-super-proc-hdl).
```
The following code fragment dissociates a super procedure from a procedure file other than the current procedure:

```
```

The following code fragment dissociates a super procedure from the current ABL session:

```
SESSION: REMOVE-SUPER-PROCEDURE(my-super-proc-hdl).
```

### REPLACE( ) method

Replaces an item in a combo box, radio set, or selection list. Replaces an existing text string in an editor with a new text string.

**Return type:** LOGICAL

**Applies to:** BROWSE widget (column), COMBO-BOX widget, EDITOR widget, RADIO-SET widget, SELECTION-LIST widget

This is the syntax for combo-box, selection-list or browse column.

**Syntax (combo-box, selection-list, or browse column)**

```
REPLACE ( { new-item-list | new-label , new-value } , { list-item | list-index } )
```

- **new-item-list**
  
  A character-string expression that specifies a single item or a delimiter-separated list of items to add to the widget.

- **new-label**

  A character-string expression that specifies the label of a label-value pair to add to the widget.

- **new-value**

  The new value assigned when a user selects the label.

**Note:** Use `new-item-list` when the widget’s entries consist of single items. Use `new-label` and `new-value` when the widget’s entries consist of label-value pairs.

- **list-item**

  A character-string expression that specifies a single value in the widget.

- **list-index**

  An integer expression that specifies the ordinal position of an existing entry in the combo box list or selection list.
For combo boxes and selection lists, REPLACE replaces `list-item` with either `new-label-list` or the label-value pair represented by `new-label` and `new-value`. If `list-item` is currently selected, the new item is not selected when it appears in the list. If the method is successful, it returns TRUE.

For browses, this method applies only to combo-box browse columns.

This is the syntax for an editor:

**Syntax (editor)**

```
REPLACE ( old-string , new-string , flag )
```

**old-string**

A character-string expression to be replaced. For the large editor widget in Windows, you can use wildcard characters for regular expression pattern matching. A question mark (?) in a particular position indicated that any single character is acceptable in that position. An asterisk (*) indicates that any group of characters is acceptable, including a null group of characters. If you want to specify a question mark (?) or asterisk (*) as a literal character rather than a wildcard character in the string, use `??` and `**` respectively.

**new-string**

A character-string expression to replace `old-string`.

**flag**

An integer expression that specifies the type of search to be performed.

For editors, REPLACE searches from the current text cursor position for an occurrence of `old-string` and replaces it with `new-string`. If the replace operation is successful, the method returns TRUE. The `flag` value determines the type of search and replace to perform. Table 99 lists the flag values that correspond to each search and replace type.

**Table 99: REPLACE flag values**

<table>
<thead>
<tr>
<th>Type of search</th>
<th>Flag value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIND-NEXT-OCCURRENCE</td>
<td>1</td>
</tr>
<tr>
<td>FIND-PREV-OCCURRENCE</td>
<td>2</td>
</tr>
<tr>
<td>FIND-CASE-SENSITIVE</td>
<td>4</td>
</tr>
<tr>
<td>FIND-GLOBAL</td>
<td>8</td>
</tr>
<tr>
<td>FIND-WRAP-AROUND</td>
<td>16</td>
</tr>
</tbody>
</table>

For a single operation, you cannot specify both FIND-NEXT-OCCURRENCE and FIND-PREV-OCCURRENCE, nor can you specify both FIND-WRAP-AROUND and FIND-GLOBAL. All other combinations of flags are valid. For example, you can specify a combination of FIND-NEXT-OCCURRENCE + FIND-GLOBAL + FIND-CASE-SENSITIVE. The default is FIND-NEXT_OCCURRENCE to search to the end of the editor string.
**REPLACE-CHILD( ) method**

Replace an old XML node with a new node. The old XML node is not deleted, only disconnected from the structure. If the new XML node is already in the tree, it is first disconnected.

**Return type:** LOGICAL  
**Applies to:** X-document object handle, X-noderef object handle

**Syntax**

```
REPLACE-CHILD( new-handle, old-handle )
```

`new-handle`  
The handle that represents the node to insert in the tree.

---

**Syntax (radio-set)**

```
REPLACE ( new-label, new-value, old-label )
```

- **new-label**: A character-string expression that specifies the new item label.
- **new-value**: The new value assigned when a user selects the item.
- **old-label**: A character-string expression that specifies the label of the item to be replaced.

The REPLACE( ) method for radio sets replaces the label, the value, or both the label and value of the specified radio item. To retain the existing label or value, substitute an empty string.

```
REPLACE ( new-label, new-value, old-label )
```

replaces the specified radio item with a new item, consisting of both a new label and a new value.

```
REPLACE ( new-label, "", old-label )
```

replaces only the label of the specified radio item, retaining the value.

```
REPLACE ( "", new-value, old-label )
```

replaces only the value of the specified radio item, retaining the label.

If the new label is longer than the existing radio set size can accommodate, the radio set appearance changes depending on setting of the AUTO-RESIZE attribute. If AUTO-RESIZE is TRUE, the radio set expands to accommodate the label. If AUTO-RESIZE is FALSE, the new label is clipped to fit the current size. However, note that the label is clipped only on the display. The new radio set item is identified by the full label regardless of its length.

If the replace operation is successful, the method returns TRUE.
old-handle

The handle that represents the node to remove from the tree.

The following code fragment gets a reference to the fourth XML node on the document root, and removes it. hNoderef is still available for use after the remove, but is unlinked from hRoot. We then replace the root’s second child with this fourth child:

```plaintext
CREATE X-NODEREF hNoderef.
CREATE X-NODEREF hChild.
...
hRoot:GET-CHILD(hNoderef,4).
hRoot:REMOVE-CHILD(hNodeRef).
hRoot:GET-CHILD(hChild,2).
hRoot:REPLACE-CHILD(hNodeRef, hChild).
```

---

**REPLACE-SELECTION-TEXT( ) method**

Replaces the currently selected text in an editor widget with the new text.

**Return type:** LOGICAL

**Applies to:** EDITOR widget

**Syntax**

```plaintext
REPLACE-SELECTION-TEXT ( new-text )
```

**new-text**

A character-string expression that specifies the new text to replace the currently selected text.

To determine what text is currently selected, query the SELECTION-TEXT attribute. If the replace operation is successful, the method returns TRUE.

---

**REPOSITION attribute**

The reposition mode of a data-relation object. If TRUE, the relation mode is REPOSITION. If FALSE, the relation mode is SELECTION. The default value is FALSE.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** Data-relation object handle

---

**REPOSITION-BACKWARD( ) method**

Moves a query object’s result list pointer back a particular number of rows.
**REPOSITION-FORWARD( ) method**

Moves a query object’s result list pointer forward a particular number of rows.

**Return type:** LOGICAL

**Applies to:** Query object handle

**Syntax**

```
REPOSITION-FORWARD ( n )
```

$n$

An integer expression representing the number of rows.

REPOSITION-FORWARD( ) always places the cursor between rows. For example:

- If the cursor is on a row—say, row 5—REPOSITION-FORWARD(1) moves the cursor to row 6, then to halfway between rows 6 and 7. From this position, GET-PREV( ) moves the cursor to row 6, while GET-NEXT( ) moves the cursor to row 7.

- If the cursor is between two rows—say, between rows 5 and 6—REPOSITION-FORWARD(1) moves the cursor to halfway between rows 6 and 7. From this position, GET-PREV( ) moves the cursor to row 6, while GET-NEXT( ) moves the cursor to row 7.

**Note:** The REPOSITION-FORWARD method corresponds to the REPOSITION statement BACKWARDS option.
REPOSITION-TO-ROW( ) method

Moves a query object’s result list pointer to the row corresponding to the specified sequence number.

**Return type:** LOGICAL

**Applies to:** Query object handle

### Syntax

```
REPOSITION-TO-ROW ( n )
```

- `n`:
  - An integer expression representing the sequence number.

**Note:** The REPOSITION-TO-ROW method corresponds to the REPOSITION statement TO ROW option.

---

REPOSITION-TO-ROWID( ) method

Moves a query object’s result list pointer to the row corresponding to the specified ROWID or ROWIDs.

To reposition to a particular row when the query is a join, supply the ROWIDs of the buffers that correspond to the desired row.

**Return type:** LOGICAL

**Applies to:** Query object handle

### Syntax

```
REPOSITION-TO-ROWID ( rowid1 [ , rowid2 ] ... | rowid-array )
```

- `rowid1 [ , rowid2 ] ...`:
  - Expressions of type ROWID representing the rowid of the first buffer, the rowid of the second buffer, etc. The maximum number of expressions is 18. If an expression contains the Unknown value (?), the AVM evaluates but ignores subsequent expressions.
rowid-array

An array of 18 or fewer elements, where each element is of type ROWID and represents
the rowid of a buffer. If an element contains the Unknown value (?), the AVM evaluates
but ignores subsequent elements.

Note: The REPOSITION-TO-ROWID method corresponds to the REPOSITION statement
TO ROWID option.

RESET( ) method

Closes the open stream and resets the SAX-writer object to its default values.

Return type: LOGICAL

Applies to: SAX-writer object handle

Syntax

```
RESET( )
```

Use this method to reuse a SAX-writer object for multiple documents or to cancel a write.

The object attributes and the output destination remain unchanged. The WRITE-STATUS
attribute is set to SAX-WRITE-IDLE.

You can call this method at any time. If the WRITE-STATUS attribute is either
SAX-WRITE-IDLE or SAX-WRITE-COMPLETE, the method call has no effect. Otherwise,
the method call closes the document and stream, and aborts the write.

See also: WRITE-STATUS attribute

RESIZABLE attribute
(Graphical interfaces only)

Indicates if the user can resize a widget at run time.

Data type: LOGICAL

Access: Readable/Writeable

Applies to: BROWSE widget (browse and column), BUTTON widget, COMBO-BOX
widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget,
LITERAL widget, RADIO-SET widget, RECTANGLE widget,
SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX
widget

If you set RESIZABLE to TRUE, the user can resize the widget. For the RESIZABLE attribute
to take effect, you must also set the SELECTABLE attribute to TRUE.
RESIZE attribute

Note: Setting the RESIZABLE attribute to TRUE enables direct manipulation events for the widget. These events take precedence over all other events. This effectively prevents data entry using the widget until all direct manipulation events are disabled (that is, until MOVABLE, RESIZABLE, and SELECTABLE are all FALSE).

RESIZE attribute
(Graphical interfaces only)

Indicates if the user can resize a window at run time.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** WINDOW widget

If the RESIZE attribute is TRUE, users can resize the window.

You can set this attribute only before the window is realized.

RESTART-ROW attribute

Allows the FILL query to be repositioned to an absolute row number. Similar to RESTART-ROWID, this attribute facilitates batching during a FILL on a ProDataSet temp-table.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** Data-source object handle

Setting this attribute is helpful when you are paging back and forth in a table and want to retrieve, for example, page 3. The BATCH-SIZE attribute is used to calculate the row where a given page begins, and RESTART-ROW is set to that value just before the FILL. This causes the FILL query to be repositioned to the correct "page". For example, to get page 3 you set RESTART-ROW to \((3-1) \times \text{BATCH-SIZE}\) to fill the third group of records.

**Syntax**

```
RESTART-ROW ( row )
```

*row*

An integer expression indicating the absolute row number to reposition the query.
RESTART-ROWID attribute

Specifies the ROWID of the data source row at which a FILL operation will start. Set this attribute before each FILL operation in a series of FILL operations to retrieve data source rows in batches. You typically set this attribute by assigning the value of the NEXT-ROWID attribute, which is set by the AVM after each FILL operation.

Note: The NEXT-ROWID attribute is not marshalled between the client and the AppServer. You are responsible for retrieving, storing, and transporting this attribute value between the client and the AppServer.

Data type: ROWID
Access: Readable/Writeable
Applies to: Data-source object handle

Syntax

data-source-handle:RESTART-ROWID( buffer-sequence-number  |  buffer-name )

data-source-handle

The handle to the Data-source object.

buffer-sequence-number

An integer that represents the sequence number of a buffer in the list of buffers for the Data-source object. Specify buffer-sequence-number to identify a buffer in the Data-source object when the Data-source object is defined against more than one database table buffer. The default is the first (or only) buffer in the Data-source object.

Note: Sequence numbers for buffers in a Data-source object start at one, where one represents the top level and subsequent numbers represent lower levels of join, if any.

buffer-name

A CHARACTER expression that evaluates to the name of a buffer in the list of buffers for the Data-source object.

If an invalid buffer is specified, this attribute returns the Unknown value (?).

When specified, the next FILL operation using this data source opens its associated query and tries to reposition the query to the given ROWID. If the reposition is successful, the AVM proceeds with the FILL operation. If the reposition is not successful, the AVM sets the RESTART-ROWID attribute to the Unknown value (?) and proceeds with the FILL operation from the top of the query at the current level (that is, without repositioning the query).

This attribute is not marshalled between the client and the AppServer.
RETAIN-SHAPE attribute

Indicates that the image should retain its aspect ratio (expand or contract equally in both dimensions).

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** IMAGE widget

Setting RETAIN-SHAPE to TRUE may leave some uncovered space at the bottom or right of the image widget. RETAIN-SHAPE is ignored if STRETCH-TO-FIT is equal to FALSE or if an icon is displayed on the image widget.

RETURN-INSERTED attribute

(Windows only)

How an editor widget behaves when a RETURN event occurs.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** EDITOR widget

If the RETURN-INSERTED attribute is TRUE, a RETURN event inserts a hard return at the cursor position, breaking the current line. Otherwise, if the editor is in a dialog box with a default button, a RETURN event chooses the default button for the dialog box. If the editor is not in a dialog box with a default button, a RETURN event inserts a hard return for any value of RETURN-INSERTED. The default value is FALSE.

You can set this attribute only before the editor widget is realized.

RETURN-VALUE attribute

The value returned from a user-defined function, attribute, or method, or a Windows DLL routine, or a UNIX shared library routine.

**Data type:** The value of the RETURN-VALUE-DATA-TYPE attribute.

**Access:** Readable

**Applies to:** Call object handle

The default is the Unknown value (?).

If you set the RETURN-VALUE-DATA-TYPE attribute to a particular data type before executing INVOKE( ), the value returned is converted to that data type.
If RETURN-VALUE-DATA-TYPE is set to its default value or to the expected data type, when the dynamic invoke returns, the value returned by the user-defined function or attribute is not converted.

When invoking a Windows DLL routine or UNIX shared library routine, RETURN-VALUE-DLL-TYPE must be set before invoking the routine. If you do not, then any value returned by the DLL routine or the UNIX shared library routine will be ignored and RETURN-VALUE will be set to the Unknown value (?).

See also RETURN-VALUE-DATA-TYPE attribute, RETURN-VALUE-DLL-TYPE attribute

RETURN-VALUE-DATA-TYPE attribute

When you dynamically invoke a user-defined function, get an attribute, or run a method, RETURN-VALUE-DATA-TYPE lets you do one of the following to the return value:

- Detect its data type
- Cause it to be converted to a different data type

If you set RETURN-VALUE-DATA-TYPE to a data type other than the expected data type before executing the dynamic invoke, the value returned is automatically converted to that data type. Otherwise, when the dynamic invoke returns, RETURN-VALUE-DATA-TYPE indicates the data type of the value returned.

Data type: CHARACTER
Access: Readable/Writable
Applies to: Call object handle

Syntax

```
RETURN-VALUE-DATA-TYPE [ = datatype ]
```

datatype

A CHARACTER expression indicating one of the following:

- “CHARACTER”
- “DATE”
- “DATETIME”
- “DATETIME-TZ”
- “DECIMAL”
- “HANDLE”
- “INT64”
- “INTEGER”
- “LOGICAL”
RETURN-VALUE-DLL-TYPE attribute

- "RAW"

The default is the Unknown value (?).

**RETURN-VALUE-DLL-TYPE attribute**

Specifies the expected data type returned from a Windows Dynamic Link Library (DLL) routine.

**Data type:** CHARACTER  
**Access:** Readable/Writable  
**Applies to:** Call object handle

The RETURN-VALUE-DLL-TYPE attribute must be assigned before invoking the call object’s INVOKE( ) method. After invocation, RETURN-VALUE contains an equivalent ABL data type which matches RETURN-VALUE-DLL-TYPE as shown in Table 100.

**Table 100: Mapping RETURN-VALUE-DLL-TYPE to RETURN-VALUE**

<table>
<thead>
<tr>
<th>RETURN-VALUE-DLL-TYPE</th>
<th>RETURN-VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>INTEGER</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>CHARACTER</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>FLOAT</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>INT64</td>
<td>INT64</td>
</tr>
<tr>
<td>LONG</td>
<td>INTEGER</td>
</tr>
<tr>
<td>MEMPTR</td>
<td>MEMPTR</td>
</tr>
<tr>
<td>SHORT</td>
<td>INTEGER</td>
</tr>
<tr>
<td>UNSIGNED-LONG</td>
<td>INT64</td>
</tr>
<tr>
<td>UNSIGNED-SHORT</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>

For example, if a DLL function is expected to return a LONG value, then RETURN-VALUE-DLL-TYPE is set to "LONG" before executing the INVOKE( ) method. After the invocation, RETURN-VALUE-DATA-TYPE has a value of "INTEGER" and RETURN-VALUE contains an INTEGER value.

If RETURN-VALUE-DLL-TYPE is not set, the DLL routine’s return value is ignored, and RETURN-VALUE is set to the Unknown value (?).

**See also** INVOKE( ) method (Handle), RETURN-VALUE attribute
**ROLES attribute**

Returns a comma-separated list of authentication domain roles for the user ID associated with the Client-principal object. This list cannot contain embedded spaces. If not specified, the AVM returns a zero-length character string.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** Client-principal object handle

Once the Client-principal object is sealed, this attribute is read-only.

**ROUNDED attribute**

(Graphical interfaces only)

Indicates whether the rectangle appears with rounded corners.

- **Data type:** LOGICAL
- **Access:** Readable/Writable
- **Applies to:** RECTANGLE widget

When TRUE, the rectangle appears with rounded corners (whether the display is set to the Windows XP Theme or the Windows Classic Theme). When FALSE, the rectangle appears with square corners.

If you set this attribute after the widget is realized, its affect is immediate (if the widget is visible).

- **See also:** GROUP-BOX attribute

**ROW attribute**

The row position of the top edge of the widget relative to the top edge of the current iteration of a parent widget or the display. Specifies the row position of the mouse cursor for the last mouse event relative to the top edge of the display.

- **Data type:** DECIMAL
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget (browse and cell), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget, LAST-EVENT system handle

This attribute is read-only for browse columns, field groups, and the LAST-EVENT handle.
For all widgets except windows, the ROW attribute specifies the location, in character units, of the top edge of the widget relative to the top edge of its parent widget. In windows, the location is relative to the top edge of the display.

For a browse column, the ROW attribute returns the Unknown value (?) if the column is hidden.

If the parent is a down frame with multiple occurrences, the ROW attribute regards the parent as the current occurrence.

For control-frames, the ROW attribute maps to the Top property of the control-frame COM object (ActiveX control container).

For the LAST-EVENT handle, the ROW attribute specifies the row location, in character units, of the last mouse event relative to the top edge of the current frame.

This attribute is functionally equivalent to the Y attribute.

---

**ROW-HEIGHT-CHARS attribute**  
(Graphical interfaces only)

Sets the row height, in characters, of a browse.

**Data type:** DECIMAL  
**Access:** Readable/Writable  
**Applies to:** BROWSE widget

All rows of a browse have the same height.

The AVM sets the ROW-HEIGHT-CHARS attribute of a browse that contains a combo-box column to the height of the combo-box, by default. You can override this setting after the browse is created.

---

**ROW-HEIGHT-PIXELS attribute**  
(Graphical interfaces only)

Sets the row height, in pixels, of a browse.

**Data type:** INTEGER  
**Access:** Readable/Writable  
**Applies to:** BROWSE widget

All rows of a browse have the same height.

The AVM sets the ROW-HEIGHT-PIXELS attribute of a browse that contains a combo-box column to the height of the combo-box, by default. You can override this setting after the browse is created.
**ROW-STATE attribute**

The current change state of the ProDataSet temp-table row associated with the buffer object handle.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer object handle

**Note:** The ROW-STATE attribute corresponds to the ROW-STATE function.

When the TRACKING-CHANGES attribute is set to TRUE for a ProDataSet temp-table, the AVM tracks changes to the data in that temp-table using a before-image temp-table that contains the original version of each row. You can think of the temp-table itself as the after-image because it contains the latest version of each row.

Every row in the after-image table that has been modified or created corresponds to a row in the before-image table. Deleted rows do not appear in the after-image table, because it reflects the current state of the data. Every row in the before-image table has a non-zero ROW-STATE, because every row is the before-image of a deleted, created, or modified row in the after-image table. Unchanged rows do not appear in the before-image table.

You can use the ROW-STATE attribute on each row in either the after-image table or the before-image table to determine whether a row has changed and how it has changed.

The possible values can be expressed as compiler constants. Table 101 lists these values.

**Table 101: Row state values**

<table>
<thead>
<tr>
<th>Compiler constant</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW-UNMODIFIED</td>
<td>0</td>
<td>The row was not modified.</td>
</tr>
<tr>
<td>ROW-DELETED</td>
<td>1</td>
<td>The row was deleted.</td>
</tr>
<tr>
<td>ROW-MODIFIED</td>
<td>2</td>
<td>The row was modified.</td>
</tr>
<tr>
<td>ROW-CREATED</td>
<td>3</td>
<td>The row was created.</td>
</tr>
</tbody>
</table>

**ROWID attribute**

The unique internal identifier of the database record currently associated with the buffer.

**Data type:** ROWID  
**Access:** Readable  
**Applies to:** Buffer object handle

**Note:** The ROWID attribute corresponds to the ROWID function.
ROW-MARKERS attribute

Indicates whether a browse uses row markers.

**Data type:** LOGICAL  
**Access:** Readable  
**Applies to:** BROWSE widget

If this attribute is set to TRUE, the browse has row markers.

ROW-RESIZABLE attribute  
(Graphical interfaces only)

Indicates whether you can change a browse’s row height.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** BROWSE widget

If ROW-RESIZABLE is TRUE, the AVM sensitizes the browse to the START-ROW-RESIZE and END-ROW-RESIZE events, which lets the user change the row height at any row juncture.

Alternately, if you add the ResizeinCell option to the [Startup] section of the progress.ini file and set it to YES, you limit the user’s ability to change the row height to only at the row marker separator. If a row does not have a row marker, the user cannot change the height of that row.

If the ResizeinCell option is set to NO, you get the default behavior where the user can change the row height at any row juncture.

**Note:** In a browse, all rows have the same height.

SAVE( ) method

Saves or sends an XML document as text generated from an X-document object.

**Return type:** LOGICAL  
**Applies to:** X-document object handle

**Syntax**

```
SAVE( mode , { file | stream | stream-handle | memptr | Longchar } )
```

*mode*

A character expression that evaluates to one of the following: “FILE”, “STREAM”, “STREAM-HANDLE”, “MEMPTR”, or “LONGCHAR”. The *mode* indicates whether the XML target is a file, a stream, a MEMPTR, or a LONGCHAR variable.
**file**

A character expression that represents the absolute or relative pathname of a new file created to save the XML text. If you specify a relative pathname, it is relative to the current working directory of the underlying operating system’s file system. If a file with the specified name already exists, the AVM verifies that the file is writeable and overwrites the file.

**stream**

A character expression that represents the name of an ABL stream. If `stream` is "", the AVM saves the document to the ABL session unnamed stream.

**stream-handle**

A character expression that represents a stream object handle.

**memptr**

A MEMPTR variable to contain the saved XML text in memory. The SAVE method allocates the required amount of memory and sets the size of the variable. You must release the memory later with a SET-SIZE() = 0.

**longchar**

A LONGCHAR variable to contain the saved XML text in memory.

If the LONGCHAR variable’s code page is fixed (that is, set using the FIX-CODEPAGE statement) and the fixed code page is not compatible with the encoding specified in the XML document’s ENCODING attribute, the SAVE( ) method returns an error and the XML document is not saved to the LONGCHAR.

If the LONGCHAR variable’s code page is not fixed, the AVM converts from the XML document’s codepage to the -cpinternal code page and saves it to the LONGCHAR variable.

The following code fragments demonstrate the use of the SAVE( ) method:

```abl
/* Saves the current tree under hDoc as memo.xml. */
DEFINE STREAM mystream.
OUTPUT STREAM mystream to memo.xml.
hdoc:SAVE("stream","mystream").

OR

/* Saves the current tree under hDoc as memo.xml. */
hdoc:SAVE("file","memo.xml").

OR

/* Saves the current tree under hDoc in memory referred to by mymem. */
DEFINE VARIABLE hDoc AS HANDLE NO-UNDO.
DEFINE VARIABLE mymem AS MEMPTR NO-UNDO.

. . .
hDoc:SAVE("memptr", mymem).
```
SAVE-FILE( ) method

Saves the current contents of the editor widget to a specified text file and sets the widget’s MODIFIED attribute to FALSE.

**Return type:** LOGICAL

**Applies to:** EDITOR widget

**Syntax**

```
SAVE-FILE ( filename )
```

`filename`

A character-string expression of the absolute or relative pathname of a file. If you specify a relative pathname, it is relative to the current working directory.

If the save is not successful, it does not change the value of the MODIFIED attribute. If the save is successful, the method returns TRUE.

In Windows, this method writes out text files with a carriage return character and a line feed character terminating each line of text. In all other interfaces, this method writes out text files with a carriage return character terminating each line of text. Also in Windows, RETURN key input writes out as x0d0d0a and in all other interfaces, writes out as x0d0a.

SAVE-ROW-CHANGES( ) method

Saves changes from one row of a ProDataSet temp-table to the associated data source.

**Return type:** LOGICAL

**Applies to:** Buffer object handle

**Syntax**

```
handle:SAVE-ROW-CHANGES( [ buffer-index | buffer-name ] [ , skip-list [ , no-lobs ] ] )
```

`handle`

A handle to a before-image buffer in a ProDataSet object.

`buffer-index`

An integer expression that specifies the index of the buffer in the data source’s buffer list. The default value is 1.

`buffer-name`

A CHARACTER expression that evaluates to the name of the buffer in the data source.
**skip-list**

An optional character expression that evaluates to a comma-separated list of field names for fields that should not be assigned after a new row is created (that is, fields to skip). For example, a key field or other fields assigned a value by a CREATE database trigger.

**no-lobs**

A logical expression indicating whether to ignore BLOB and CLOB fields in the save operation. If TRUE, BLOB and CLOB fields are ignored during the save operation. If FALSE, BLOB and CLOB fields are saved along with the other fields. The default value is FALSE (that is, BLOB and CLOB fields are included in the save operation).

**Caution:** If another user did change a LOB field since you read the record, the assignment might not be appropriate. You get no warning of such problems with this option. Therefore, before using this option, you must understand the nature of your data and be sure that using this option will not result in inconsistent or out-of-date data in the database.

The data source must be attached before calling this method. If there is no data source, or special processing is needed, you must write the code to save the changes instead of using the SAVE-ROW-CHANGES( ) method.

The AVM saves ProDataSet buffer changes to the associated data source based on the current MERGE-BY-FIELD attribute and PREFER-DATASET attribute settings.

When MERGE-BY-FIELD is TRUE, the AVM merges changes from a ProDataSet temp-table buffer to the associated data source on a field-by-field basis. When MERGE-BY-FIELD is FALSE, the AVM does not merge changes on a field-by-field basis.

**Note:** Merging a large number of changes from a ProDataSet object to the data source on a field-by-field basis is slower than saving changes buffer-by-buffer.

Before saving any changes, the AVM compares the before-image of the ProDataSet temp-table buffer or field, saved while tracking changes for the buffer, to the corresponding buffer or field in the data source to determine whether the data in the data source has changed since being read.

If the data in the data source has not changed, the AVM copies the ProDataSet buffer or field to the data source. If the data in the ProDataSet buffer or field was deleted, the AVM deletes the data from the data source.

If the data in the data source has changed, the AVM saves the ProDataSet buffer changes based on the current PREFER-DATASET attribute setting. When PREFER-DATASET is TRUE, the AVM copies the data from ProDataSet buffer or field to the data source regardless of any changes made to the data in the data source since the data was read. When PREFER-DATASET is FALSE, the AVM does not copy the data from the ProDataSet buffer or field to the data source. The AVM copies the conflicting data from the data source to the ProDataSet buffer or field, instead, and sets the ERROR attribute and DATA-SOURCE-MODIFIED attribute to TRUE.

If the AVM encounters an error, it sets the value of the ERROR attribute to TRUE for the associated ProDataSet object handle, Temp-table object handle, and Buffer object handle.
SAVE-WHERE-STRING attribute

Returns the WHERE clause used to find the database buffer identified by the buffer-index or buffer-name in the Data-source object.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** Data-source object handle

**Syntax**

```
data-source-handle:SAVE-WHERE-STRING( buffer-index | buffer-name )
```

- **data-source-handle**
  
  The handle to the Data-source object.

- **buffer-index**
  
  The 1-based index of the buffer in the list of buffers for the Data-source object.

- **buffer-name**
  
  The name of a before-image table in the list of buffers for the Data-source object. The default is the first (or only) buffer in the Data-Source buffer list.

SAX-PARSE( ) method

Performs a single-call parse of an XML document associated with a SAX-reader object.

**Return type:** None

**Applies to:** SAX-reader object handle

**Syntax**

```
SAX-PARSE ( )
```

Returns when one of the following occurs:

- The parser reaches the end of the document.
- A callback invokes RETURN ERROR.
- An error occurred because the parser could not start or could not continue parsing.

While SAX-PARSE( ) is running, each time the parser detects an XML element, the AVM invokes the corresponding callback. Callbacks reside in a procedure file whose handle has been assigned to the HANDLER attribute.

**Note:** SAX-PARSE( ) does not have a return value. To detect if an error has occurred, add NO-ERROR to the call and when it returns, check ERROR-STATUS:ERROR.
**SAX-PARSE-FIRST( ) method**

Initializes and begins a progressive-scan parse of an XML document associated with a SAX-reader object.

**Return type:** None

**Applies to:** SAX-reader object handle

**Syntax**

```
SAX-PARSE-FIRST ( )
```

To continue a progressive-scan parse, call SAX-PARSE-NEXT( ) repeatedly.

When SAX-PARSE-FIRST( ) executes, the AVM invokes the StartDocument callback, if there is one. SAX-PARSE-FIRST( ) raises an ABL error if the parser fails, for any reason, to start parsing the XML source.

If SAX-PARSE-FIRST( ) is called on a source file already being parsed with SAX-PARSE-NEXT( ), the parser reinitializes the parsing process.

SAX-PARSE-FIRST( ) can be called with SAX-reader in any state.

**Note:** SAX-PARSE-FIRST( ) does not have a return value. To detect if an error has occurred, add NO-ERROR to the call and when it returns, check ERROR-STATUS:ERROR.

---

**SAX-PARSE-NEXT( ) method**

Continues a progressive-scan parse of an XML document associated with a SAX-reader object.

**Return type:** None

**Applies to:** SAX-reader object handle

**Syntax**

```
SAX-PARSE-NEXT ( )
```

SAX-PARSE-NEXT( ) returns after the parser finds the next XML token in the XML source and the AVM invokes the corresponding callback, if it exists.

When SAX-PARSE-NEXT( ) starts, an error is raised if the PARSE-STATUS attribute is anything other than SAX-RUNNING. This might occur if:

- SAX-PARSE-NEXT( ) is called before SAX-PARSE-FIRST( ) is called
- STOP-PARSING( ) is called

Eventually, SAX-PARSE-NEXT( ) fails to find another XML token (assuming the parse does not stop early). When this happens, the AVM sets the PARSE-STATUS attribute to SAX-COMPLETE. If SAX-PARSE-NEXT( ) is called at that point, an error is raised.
Note: SAX-PARSE-NEXT() does not have a return value. To detect if an error has occurred, add NO-ERROR to the call and when it returns, check ERROR-STATUS:ERROR.

To stop a progressive-scan parse, you can refrain from calling SAX-PARSE-NEXT(). however, when you detect that it is time to stop, you will most likely be in a callback, so you need a way to communicate that it is time to stop to the driver (where SAX-PARSE-NEXT() is called). A convenient way to do that is to call SELF:STOP-PARSING(), since that causes the AVM to set the value of PARSE-STATUS to SAX-COMPLETE.

SCHEMA-CHANGE attribute

Relaxes the requirement for exclusive access to a database in order to make the following schema changes online:

- Add new sequences.
- Add new tables, as well as any associated fields, indexes, and database triggers (which must be added within the same transaction).
- Add new fields to an existing table. (You cannot define ASSIGN triggers for new fields while the database is online.)
- Add new inactive indexes to an existing table.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: SESSION system handle

Set this attribute to “NEW OBJECTS” to activate this feature; and to the empty string (“”) or the Unknown value (?) to deactivate this feature.

SCHEMA-LOCATION attribute

Determines the list of namespace/location pairs of an XML Schema file to validate against.

Data type: CHARACTER
Access: Readable/Writable
Applies to: X-document object handle, SAX-reader object handle

Contains the XML Schema file namespace/location pairs list for the object that the parser is using to validate against. The value pairs are separated by white space.

The default is an empty string (“”).

The syntax for the list is the same as the attribute schemaLocation in an XML document. The first member of each pair is the namespace and the second member is the location where to find to an appropriate XML Schema file. The list is written as pairs of target namespace and locations where each value is separated by white space, using the following format:
SCHEMA-MARSHAL attribute

Here is an example of this method call:

```
namespace1 location1 namespace2 location2 namespace3 location3
```

Note that namespace and XML Schema file locations specified programatically with this method take precedence over namespaces or schemas declared in XML documents or imported elements.

To clear the schema location list set SCHEMA-LOCATION to an empty string (""").

The previous example could also be achieved using the ADD-SCHEMA-LOCATION() method twice:

```
hXdoc:SCHEMA-LOCATION = "http://www.example.com com.xsd
http://www.example.org org.xsd"
```

```
hXdoc:ADD-SCHEMA-LOCATION("http://www.example.com", "com.xsd").
hXdoc:ADD-SCHEMA-LOCATION("http://www.example.org", "org.xsd").
```

### SCHEMA-MARSHAL attribute

Specifies the amount of schema information to marshal for a temp-table parameter. The temp-table may be an independent temp-table or a member of a ProDataSet object. The default value is FULL (which includes all schema information for the temp-table parameter).

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Temp-table object handle

Table 102 lists the SCHEMA-MARSHAL attribute values.

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULL</td>
<td>Includes all schema information for a temp-table parameter</td>
</tr>
<tr>
<td>MIN</td>
<td>Minimizes schema information for a temp-table parameter</td>
</tr>
<tr>
<td>NONE</td>
<td>Excludes schema information for a temp-table parameter</td>
</tr>
</tbody>
</table>

If set to the Unknown value (?), the default value is FULL.
**SCHEMA-PATH attribute**

A delimiter-separated list of directory paths used to locate the XML Document Type Definition (DTD) associated with a particular XML document. It is searched if the XML document contains a relative path to the DTD.

**Data type:** CHARACTER

**Access:** Readable/Writable

**Applies to:** SAX-reader object handle, X-document object handle

The default is the Unknown value (?).

To separate directory paths, use a comma, or a delimiter character that your operating system recognizes.

To separate directory names and filenames within a path, use the UNIX format (forward slashes) or the standard format for your operating system.

SCHEMA-PATH can include HTTP URLs, but they might slow your application since accessing a DTD over the Web might take significantly longer than doing so over a file network.

SCHEMA-PATH cannot contain ABL procedure libraries (.pl files).

File pathnames cannot contain embedded commas. The AVM replaces delimiter characters with commas, so the resulting SCHEMA-PATH can be accessed using the ENTRY function.

**Note:** When the AVM searches for the DTD, the AVM concatenates each entry in SCHEMA-PATH with SYSTEM-ID (an attribute in DOM and a parameter of the ResolveEntity callback in SAX), which indicates the system ID of the external DTD. SYSTEM-ID might be as simple as a filename or as complex as a relative path.

For more information on accessing XML documents using the Document Object Model (DOM) or Simple API for XML (SAX) interfaces, see *OpenEdge Development: Working with XML*.

**SCREEN-LINES attribute**

The number of display lines available in the window, in character units.
**SCREEN-VALUE attribute**

The data value in the screen buffer associated with the widget.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget (cell), COMBO-BOX widget, EDITOR widget, FILL-IN widget, LITERAL widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

Note that setting the SCREEN-VALUE attribute does not affect the record buffer. To apply the updated value to the record buffer you must explicitly assign the field or variable. Likewise, assigning the record buffer does not affect the screen buffer. To display a value in the record buffer, you must explicitly assign it to the SCREEN-VALUE attribute or implicitly move it to the screen buffer using a DISPLAY or UPDATE statement.

For combo boxes, this attribute returns the screen buffer value of the combo box fill-in. If no item in the list is selected or the list is empty, this attribute returns the Unknown value (?). Setting this attribute to an item in the list deselects the previously selected item and assigns the value of the selected item to the fill-in screen buffer. For SIMPLE and DROP-DOWN combo boxes, if the new value in the fill-in is not an item in the list, the fill-in screen buffer is set to the new value and no item in the list is selected. For DROP-DOWN-LIST combo boxes, if the new value in the fill-in is not an item in the drop down list, the AVM ignores the value and displays a warning message.

**Note:** When a selection-list has the MULTIPLE attribute, setting the SCREEN-VALUE does not clear existing selections. See the “MULTIPLE attribute” section on page 1601, for more information on how multi-selection operates.

For browse cells, screen values are applied to the buffers automatically when the user leaves the row. If the browse has the NO-ASSIGN option specified in the DEFINE BROWSE statement or it is a dynamic browse, then you must apply the screen values.

Changing the SCREEN-VALUE attribute for a browse column is useful in setting the cells in a non-database browse column.

**Note:** If you assign a value to the SCREEN-VALUE attribute of a widget and display the widget using a DISPLAY or UPDATE statement, the value you assigned appears as the initial value.

In Windows, SCREEN-VALUE applies to the regular editor and to the large editor.
SCROLL-BARS attribute

Indicates whether scroll bars appear in a window.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** WINDOW widget

If the SCROLL-BARS attribute is TRUE, scroll bars appear for the window when a user resizes the window to a size smaller than virtual height or width of the window. The RESIZE attribute controls the ability to resize a window. The VIRTUAL-HEIGHT-CHARS, VIRTUAL-WIDTH-CHARS, VIRTUAL-HEIGHT-PIXELS, and VIRTUAL-HEIGHT-PIXELS attributes control the virtual or maximum size of a window.

SCROLL-TO-CURRENT-ROW( ) method

Scrolls a browse (if necessary) to bring the currently selected row into view. If the browse supports multiple selections, then SCROLL-TO-CURRENT-ROW( ) brings the most recently selected row into view.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
SCROLL-TO-CURRENT-ROW ( )
```

The position of the scrolled row is the first row in the browse viewport, unless the current row is already visible. In this case, the current row remains in the original position. If the row is successfully scrolled into view (or if the scroll is unnecessary), the method returns TRUE.

SCROLL-TO-ITEM( ) method

Scrolls a selection list so that the specified item appears at the top of the list.

**Return type:** LOGICAL

**Applies to:** SELECTION-LIST widget

**Syntax**

```
SCROLL-TO-ITEM ( list-item | list-index )
```

**list-item**

A character-string expression that specifies a single value in the selection list.
list-index

An integer expression that specifies the ordinal position (first, second, third, etc.) of an entry in the selection list.

If the method is successful, it returns TRUE.

**SCROLL-TO-SELECTED-ROW( ) method**

Scrolls a browse (if necessary) to bring a specified selected row into view.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
SCROLL-TO-SELECTED-ROW ( n )
```

n

An integer expression that specifies a selected row within the browse.

The AVM maintains a numbered list of selected rows, starting at 1. When the SCROLL-TO-SELECTED-ROW( n ) method is encountered, the AVM searches this list to find the nth selected row. If the row is successfully scrolled into view (or if the scroll is unnecessary), the method returns TRUE.

**SCROLLABLE attribute**

The scrolling capabilities of a frame or a dialog box.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** DIALOG-BOX widget, FRAME widget

If the SCROLLABLE attribute is TRUE, the frame or dialog box can be bigger than the display space allotted to it (that is, it is scrollable). If SCROLLABLE is FALSE, the frame or dialog box must fit within the allotted display space; it cannot be made to scroll. The default value is TRUE. The VIRTUAL-HEIGHT-CHARS, VIRTUAL-HEIGHT-CHARS, VIRTUAL-HEIGHT-CHARS, and VIRTUAL-HEIGHT-CHARS attributes control the virtual or maximum size of a frame or dialog box.

**SCROLLBAR-HORIZONTAL attribute**

Indicates whether a horizontal scroll bar appears in an editor or a selection list.
SCROLLBAR-VERTICAL attribute

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** EDITOR widget, SELECTION-LIST widget

If the SCROLLBAR-HORIZONTAL attribute is TRUE, a horizontal scroll bar appears on the bottom edge of the widget. For an editor widget, horizontal scrolling is always enabled whether or not a horizontal scroll bar is enabled. For a selection list, the scroll bar must be enabled to scroll the list. The default value is FALSE.

**Note:** If the SCROLLBAR-HORIZONTAL attribute is set to TRUE, then WORD-WRAP is automatically set to FALSE. Likewise, if you set the WORD-WRAP attribute to TRUE, then SCROLLBAR-HORIZONTAL is automatically set to FALSE.

You can set this attribute only before the widget is realized.

---

SCROLLBAR-VERTICAL attribute

*(Graphical interfaces only)*

Indicates whether a vertical scroll bar appears in a browse, editor or a selection list.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, EDITOR widget, SELECTION-LIST widget

If the SCROLLBAR-VERTICAL attribute is TRUE, a vertical scroll bar appears on the right side of the widget. For an editor widget, vertical scrolling is always enabled whether or not a vertical scroll bar is enabled. For a selection list, the scroll bar must be enabled to scroll the list. The default value is FALSE.

For browses, the SCROLLBAR-VERTICAL attribute defaults to TRUE unless the DEFINE BROWSE statement Browse Options phrase includes the NO-SCROLLBAR-VERTICAL option. When the vertical scroll bar appears, it appears on the right side of the browse.

For editors and selection lists, you can set this attribute only before the widget is realized.

---

SEAL() method

Seals a Client-principal object with the specified message authentication code (MAC). Sealing a Client-principal object signifies that the user identity from the authentication domain has successfully logged into that domain. Once logged in, you can use the sealed Client-principal object to set a user ID using either the SET-CLIENT() method or SET-DB-CLIENT function.

You must set the following attributes on the Client-principal object before you can seal the object:

- USER-ID attribute
- DOMAIN-NAME attribute
• SESSION-ID attribute

If you do not set these attributes, the AVM generates a run-time error.

You can seal a Client-principal object only once per user login session. Then, you can use the VALIDATE-SEAL( ) method to validate the seal whenever necessary.

Once sealed, you cannot set any new or existing properties or attributes for the object.

**Return type:** LOGICAL

**Applies to:** Client-principal object handle

**Syntax**

```plaintext
SEAL( key )
```

*key*

A character expression containing the key of the authentication domain that authenticated the user ID. The AVM uses this key to generate the MAC with which to seal the Client-principal object. The AVM converts this key to UTF-8 before using it, which ensures a consistent value regardless of code page settings. A matching authentication domain key must be registered in a trusted authentication domain registry before you can validate and use the user ID represented by the Client-principal object.

If successful, this method returns TRUE. The AVM also sets the SEAL-TIMESTAMP attribute with the time stamp of when the Client-principal object was sealed, and sets the LOGIN-STATE attribute to “LOGIN”.

The AVM also checks the LOGIN-EXPIRATION-TIMESTAMP attribute. If the Client-principal object expires before you can seal it, the AVM sets the LOGIN-STATE attribute to “EXPIRED” and returns FALSE.

Calling this method generates an audit event and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.

The following code fragment illustrates how to use the SEAL( ) method:

```plaintext
DEFINE VARIABLE hCP AS HANDLE NO-UNDO
DEFINE VARIABLE key  AS CHARACTER NO-UNDO.
DEFINE VARIABLE lResult AS LOGICAL NO-UNDO.

. . .
CREATE CLIENT-PRINCIPAL hCp.

lResult = hCP:SEAL(key).
```
SEAL-TIMESTAMP attribute

Returns the time stamp of when the Client-principal object was sealed, as a DATETIME-TZ. If the Client-principal object is not sealed, this attribute returns the Unknown value (?).

Data type: DATETIME-TZ
Access: Readable
Applies to: Client-principal object handle
See also: SEAL( ) method, VALIDATE-SEAL( ) method

SEARCH( ) method

Searches for a specified string in an editor widget starting from the current text cursor position. For graphical interfaces only, the string is highlighted when found.

Return type: LOGICAL
Applies to: EDITOR widget
Syntax

\[
\text{SEARCH } ( \text{string}, \text{flag} )
\]

string

The character-string expression for which to search.

Note: You cannot specify wildcard characters in the search string.

flag

An integer expression that specifies the type of search to be performed.

The flag expression determines what type of search to perform. Table 103 lists the flag values that correspond to each search type.

Table 103: SEARCH flag values

<table>
<thead>
<tr>
<th>Type of search</th>
<th>Flag value</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIND-NEXT-OCCURRENCE</td>
<td>1</td>
</tr>
<tr>
<td>FIND-PREV-OCCURRENCE</td>
<td>2</td>
</tr>
<tr>
<td>FIND-CASE-SENSITIVE</td>
<td>4</td>
</tr>
</tbody>
</table>
For a single search operation, you cannot specify both FIND-NEXT-OCCURRENCE and FIND-PREV-OCCURRENCE. Any other combination of these flags is valid. To do multiple searches, you add the flag values. For example, you can specify FIND-PREV-OCCURRENCE and FIND-WRAP-AROUND by adding their flag values, 2 and 16, to get SEARCH(string, 18).

If the operation is successful, the method returns TRUE.

### SELECT-ALL() method

Selects all rows, or a range of rows, in a query connected to the browse.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```c
SELECT-ALL ( [ starting-row-table1, starting-row-table2, ... ending-row-table1, ending-row-table2 ... ] )
```

*starting-row-table1*

A variable of type ROWID representing the first row in the first table to select.

*starting-row-table2*

A variable of type ROWID representing the first row in the second table to select.

*ending-row-table1*

A variable of type ROWID representing the last row in the first table to select.

*ending-row-table2*

A variable of type ROWID representing the last row in the second table to select.

If you not specify parameters, the SELECT-ALL method selects all rows.

If you specify the starting row and the ending row, the SELECT-ALL method selects all rows between the starting row and the ending row inclusive.

If the query is a join, a ROWID for each table in the query can be specified for the starting row and the ending row. A maximum of 40 parameters is allowed which allows the user to specify a 20-table join, 20 ROWIDs for the starting row, and 20 ROWIDs for the ending row.
SELECT-FOCUSED-ROW( ) method

Selects the row that currently has focus in a browse widget, even if it is not currently displayed.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
SELECT-FOCUSED-ROW ( )
```

This method repositions the query to that row and copies the record into the database buffer. The browse automatically scrolls to the selected row. You can use this method after a REPOSITION statement to position a query to a selected row.

SELECT-NEXT-ROW( ) method

Deselects all currently selected rows in a browse and selects the row after the deselected row.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
SELECT-NEXT-ROW ( )
```

This method also repositions the query to the new row and copies the record into the database buffer. The browse automatically scrolls to the selected row if it is out of view.

This method is intended for use with a browse that supports the selection of a single row at a time (MULTIPLE attribute is set to FALSE). If more than one row is selected when you execute this method, all of the selected rows are deselected and the record after the last selected row becomes the selected row.

SELECT-PREV-ROW( ) method

Deselects a currently selected row in a browse and selects the row before the deselected row.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
SELECT-PREV-ROW ( )
```

This method also repositions the query to the new row and copies the record into the database buffer. The browse automatically scrolls to the selected row if it is out of view.
This method is intended for use with a browse that supports the selection of a single row at a time (MULTIPLE attribute is set to FALSE). If more than one row is selected when you execute this method, all of the selected rows are deselected and the record before the last selected row becomes the selected row.

**SELECT-ROW( ) method**

Selects the specified row if it is currently in the browse viewport. In a single-select browse, the previously selected row is deselected. No rows are deselected in a multiple-select browse.

**Return type:** LOGICAL

**Applies to:** BROWSE widget

**Syntax**

```
SELECT-ROW( n )
```

*n*

An integer expression specifying the ordinal position of a row within the browse.

This method also repositions the query to that row and copies the record into the database buffer.

**SELECTABLE attribute**

(Graphical interfaces only)

Indicates whether a widget is selectable for direct manipulation at run time.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

If the SELECTABLE attribute is TRUE, users can select and deselect the widget (that is, activate SELECTION and DESELECTION events for the widget). You must also set the SELECTABLE attribute to TRUE for the RESIZABLE attribute to take effect, allowing the user to resize the widget.

**Note:** Setting the SELECTABLE attribute to TRUE enables direct manipulation events for the widget. These events take precedence over all other events. This effectively prevents data entry using the widget until all direct manipulation events are disabled (that is, MOVABLE, RESIZABLE, and SELECTABLE are all set to FALSE). Also, vertical scrollbars are disabled until no direct manipulation can occur (that is, MOVABLE, RESIZABLE, and SELECTABLE are all set to FALSE).
SELECTED attribute
(Graphical interfaces only)

Indicates whether a widget is selected (highlighted).

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

This attribute can be set in two ways—when the widget’s SELECTABLE attribute is TRUE and the user selects the widget, or by setting the SELECTED attribute to TRUE from the AVM whether or not its SELECTABLE attribute is TRUE. Although setting SELECTED to TRUE from the AVM highlights the widget, this does not activate a SELECTION event for the widget.

SELECTION-END attribute

The offset of the first character after the end of the currently selected text in the widget.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** BROWSE widget (column), COMBO-BOX widget, EDITOR widget, FILL-IN widget

If no text is currently selected, SELECTION-END has the Unknown value (?).

If the editor is not already realized and you reference its SELECTION-END attribute, the AVM realizes the widget.

In Windows, both the regular editor and the large editor support SELECTION-END.

SELECTION-START attribute

The offset of the first character of the currently selected text in the widget.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** BROWSE widget (column), COMBO-BOX widget, EDITOR widget, FILL-IN widget

If the editor is not already realized and you reference its SELECTION-START attribute, the AVM realizes the widget.

In Windows, both the regular editor and the large editor support SELECTION-START.
**SELECTION-TEXT attribute**

The currently selected text in the widget.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** BROWSE widget (column), COMBO-BOX widget, EDITOR widget, FILL-IN widget

You can read this attribute to access the text the user has selected. To change or remove the currently selected text, use the REPLACE-SELECTION-TEXT() method.

If the editor is not already realized and you reference its SELECTION-TEXT attribute, the AVM realizes the widget.

---

**SENSITIVE attribute**

Indicates whether a widget can receive input focus or events. Indicates whether certain ABL objects can receive events.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU widget, MENU-ITEM widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, Server socket object handle, SLIDER widget, Socket object handle, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

For widgets, if the SENSITIVE attribute is TRUE, the user can give input focus to the widget or can select, move, or resize it (if other attributes are set). A field-level widget must be specified in a frame before you can set the SENSITIVE attribute. The ENABLE statement implicitly sets this attribute to TRUE, and the DISABLE statement sets it to FALSE.

If the READ-ONLY attribute is TRUE for the widget, the SENSITIVE attribute has no effect except to grey out the widget in some environments.

You can use the SENSITIVE attribute to reset the MODIFIED attribute. For example, when the screen-value of a fill-in field is changed, MODIFIED is set to TRUE. If you then set SENSITIVE to FALSE and then to TRUE, you enable the fill-in for further input and the MODIFIED attribute is reset to FALSE.

For the socket and server socket objects, the SENSITIVE attribute indicates whether the object can receive events. The default value of this attribute is TRUE for socket and server socket objects.

If the SENSITIVE attribute is set to FALSE for the socket object, the AVM will not execute the READ-RESPONSE procedure for the socket even if the READ-RESPONSE event occurs.
If the SENSITIVE attribute is set to FALSE for the server socket object, the AVM will stop accepting connections on the port associated with the server socket.

**Note:** If an application knows it will not receive data on a socket during some period of time, it should set this attribute to FALSE. This allows the application to run more efficiently since the AVM does not monitor the socket if its SENSITIVE attribute is set to FALSE. Data can still be written to an insensitive socket object. When the attribute is set to TRUE, the AVM checks the socket for data.

---

**SEPARATORS attribute**  
*(Graphical interfaces only)*

Indicates whether the AVM displays the row and column separators of a browse widget.

- **Data type:** LOGICAL  
- **Access:** Readable/Writable  
- **Applies to:** BROWSE widget

If SEPARATORS is TRUE, row and column separators appear in the widget. Otherwise, they do not. This attribute can be initialized with the SEPARATORS or NO-SEPARATORS option of the DEFINE BROWSE statement.

---

**SEPARATOR-FGCOLOR attribute**  
*(Graphical interfaces only)*

Sets the color of a browse’s separators.

- **Data type:** INTEGER  
- **Access:** Readable/Writable  
- **Applies to:** BROWSE widget

If you set a browse’s SEPARATOR-FGCOLOR attribute and the separators appear, they have the color you specified.
**SERIALIZE-HIDDEN attribute**

Indicates whether this field is written when the temp-table is serialized, for example into JSON or XML.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** Buffer-field object handle

This attribute’s purpose overlaps with the XML-NODE-TYPE attribute. Because of this overlap, the attributes interact as follows:

- The WRITE-XML( ) method always uses the XML-NODE-TYPE attribute value. If you set a value for the XML-NODE-TYPE attribute, it keeps that value regardless of how you set the SERIALIZE-HIDDEN attribute.

- If you do not set the XML-NODE-TYPE attribute and set the SERIALIZE-HIDDEN attribute to TRUE, the AVM sets XML-NODE-TYPE to "HIDDEN".

- If you do not set the XML-NODE-TYPE attribute and set the SERIALIZE-HIDDEN attribute to FALSE, the AVM sets XML-NODE-TYPE to "ELEMENT".

- If you do not set either attribute, the AVM sets XML-NODE-TYPE to "ELEMENT" and sets SERIALIZE-HIDDEN to FALSE.

For more information about using this attribute, see the documentation on working with JSON.

**See also:** WRITE-JSON( ) method, WRITE-XML( ) method, XML-NODE-TYPE attribute

---

**SERIALIZE-NAME attribute**

Indicates the name of a ProDataSet, a temp-table, a temp-table buffer, or a temp-table buffer-field object as it should appear when serialized, for example into JSON or XML.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** Buffer object handle, Buffer-field object handle, ProDataSet object handle, Temp-table object handle

This attribute’s purpose overlaps with the XML-NODE-NAME attribute. Because of this overlap, the attributes interact as follows:

- The READ-XML( ) and WRITE-XML( ) methods always use the XML-NODE-NAME attribute value. If you set a value for the XML-NODE-NAME attribute, it keeps that value regardless of how you set the SERIALIZE-NAME attribute.

- If you do not set the XML-NODE-NAME attribute and set the SERIALIZE-NAME attribute, the AVM sets XML-NODE-NAME equal to SERIALIZE-NAME.

- If you do not set either attribute, the AVM sets both to the ABL object name.
SERVER attribute

Use this attribute when the serialized name either contains invalid characters for an ABL name or the serialized name is an ABL keyword.

For more information about using this attribute, see the documentation on working with JSON.

See also: READ-JSON( ) method, READ-XML( ) method, WRITE-JSON( ) method, WRITE-XML( ) method, XML-NODE-NAME attribute

SERVER attribute

The server handle to one of the following:

- An AppServer on which:
  - An asynchronous request is running
  - The specified remote persistent procedure is running
  - You are running remote dynamic procedure or user-defined function
  - WebClient application files are accessed
- A server that hosts a Web service:
  - On which an asynchronous Web service operation is running
  - To which a Web service procedure object is bound

Data type: HANDLE
Access: Readable/Writable
Applies to: Asynchronous request object handle, Call object handle, CODEBASE-LOCATOR system handle, Procedure object handle

For an asynchronous request object handle, the SERVER attribute refers to the AppServer where an asynchronous procedure call is active, or it refers to the server that hosts a Web service where an asynchronous operation is executing.

For a procedure handle, the SERVER attribute is read-only and valid only on a proxy persistent procedure handle that references an active persistent procedure running in the context of an AppServer or that references a port type procedure object in the context of a Web service (that is, where the handle PERSISTENT and PROXY attributes are both set to TRUE). Thus, for a persistent procedure, the attribute refers to the AppServer where it runs, and for a port type procedure object, the attribute refers to the server that hosts the Web service. Otherwise, the SERVER attribute is set to the Unknown value (?).

For the call object handle, the SERVER attribute is both readable or writable and specifies the handle to an AppServer containing logic you want to invoke dynamically.

Note: Do not confuse SERVER and IN-HANDLE. SERVER indicates a handle to an AppServer containing logic you want to invoke dynamically. IN-HANDLE indicates a handle to a running persistent procedure containing logic (internal procedures and user-defined functions) you want to invoke dynamically.
For the CODEBASE-LOCATOR system handle, the SERVER attribute is read-only and returns the server handle to a connected AppServer for accessing WebClient application files. Valid only if LOCATOR-TYPE is "AppServer".

To check the validity of a handle, use the VALID-HANDLE function. For more information on the AppServer, see *OpenEdge Application Server: Developing AppServer Applications*. For more information on Web services, see *OpenEdge Development: Web Services*.

## SERVER-CONNECTION-BOUND attribute
(AppServer only)

Indicates if the current AppServer agent is bound to a particular client application.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** SESSION system handle

This attribute is valid only if the REMOTE attribute is TRUE.

If the SERVER-CONNECTION-BOUND attribute is TRUE, the current session is bound to a client application. Otherwise, it is FALSE.

On a stateless or state-free AppServer, if the SERVER-CONNECTION-BOUND-REQUEST attribute is set to FALSE to unbind the connection, the connection remains bound and the SERVER-CONNECTION-BOUND attribute remains TRUE as long as remote persistent procedures remain active for the connection.

On a state-aware or state-reset AppServer, the SERVER-CONNECTION-BOUND attribute is always set to TRUE.

## SERVER-CONNECTION-BOUND-REQUEST attribute
(AppServer only)

Tells an AppServer agent running on a stateless AppServer to bind or unbind its current client connection.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** SESSION system handle

This attribute is valid only if the REMOTE attribute is TRUE and the operating mode is stateless.

When set to TRUE, requests that the AppServer agent makes its connection bound to the current client connection identified by the SERVER-CONNECTION-ID attribute.
When set to FALSE, requests that the AppServer agent makes its connection unbound from the currently bound client connection pending the deletion of all remote persistent procedures running in the session. When all remote persistent procedure for the connection have been deleted, the AppServer agent becomes available to service a different client connection. The SERVER-CONNECTION-BOUND attribute for the session is also set to FALSE when the AppServer agent becomes available.

In state-free operating mode, any attempt to set this attribute raises a WARNING condition in the AppServer agent, which writes a message to the AppServer log file, and the value remains unchanged. You can handle the WARNING condition by including the NO-ERROR option in the statement that attempts to set the value, and checking ERROR-STATUS:NUM-MESSAGES for a value greater than zero. In state-free operating mode, this attribute always has the Unknown value (?).

**Note:** This attribute has no effect on AppServer sessions running in state-aware or state-reset mode.

### SERVER-CONNECTION-CONTEXT attribute
*(AppServer only)*

An application-determined value that you set within an AppServer agent. The AVM passes this value to each AppServer agent that executes a request on behalf of the client connection identified by the SERVER-CONNECTION-ID attribute.

- **Data type:** CHARACTER
- **Access:** Readable/Writeable
- **Applies to:** SESSION system handle

This attribute is valid only if the REMOTE attribute is TRUE.

When a client application requests a connection with an AppServer, the AppServer broker creates an area to store this value for the connection. The initial value is the Unknown value (?).

This attribute, while available in all AppServer operating modes, has practical application only on a stateless AppServer, where more than one AppServer agent can service the same client connection. This value is available to any Connect procedure, Activate procedure, Deactivate procedure, or Disconnect procedure that you have configured for the AppServer, as well as any application procedure. Thus, each AppServer agent that services a client connection can pass context information to the next.

For an AppServer agent, the AVM sets the SERVER-CONNECTION-CONTEXT attribute to the Unknown value (?) each time a new connection is assigned to the process. If the AppServer operating mode is state-aware or state-reset, the AppServer agent procedure can also reset this attribute to an application-specific value. However, any such value does not last beyond the current client connection within the current AppServer agent session. Thus, AppServer agents running on a state-aware or state-reset AppServer cannot pass information among themselves using this attribute.
In state-free operating mode, any attempt to set this attribute raises a WARNING condition in the AppServer agent, which writes a message to the AppServer log file, and the value remains unchanged. You can handle the WARNING condition by including the NO-ERROR option in the statement that attempts to set the value, and checking ERROR-STATUS:NUM-MESSAGES for a value greater than zero. In state-free operating mode, this attribute always has the Unknown value (?).

SERVER-CONNECTION-ID attribute (AppServer only)

Returns the run-time connection ID of the current client connection assigned to this AppServer session.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** SESSION system handle

This attribute is valid only if the REMOTE attribute is TRUE.

This value is assigned by the AppServer broker when an AppServer accepts a connection request from a client application. The AppServer broker and all AppServer agents use the connection ID as an identifier when they log any information associated with the connection. This same connection ID is available to the AppServer agent using the SERVER-CONNECTION-ID attribute and to the connected ABL client using the CLIENT-CONNECTION-ID attribute on the server handle connected to this AppServer.

The value of the connection ID is guaranteed to be globally unique for all time within a single computer network. Connection IDs can be compared to each other strictly for equality, but other types of comparisons are irrelevant.

The AVM ensures that the SERVER-CONNECTION-ID attribute for each AppServer agent is set to the connection ID for the connection that is assigned to the AppServer agent. Each time a new connection is assigned to an AppServer agent, a new value is assigned to the SERVER-CONNECTION-ID attribute.

This attribute is available to any Connect procedure or Disconnect procedure that you have configured for the AppServer. It maintains the same value for these and all other AppServer procedures executed on behalf of the same connection.

If the AppServer operating mode is stateless, the AppServer broker resets the SERVER-CONNECTION-ID attribute for each AppServer agent to the ID of the connection each time it executes a request. The connection ID for a bound stateless AppServer agent remains the same until the server process becomes unbound and receives a request from a new unbound connection.

If the AppServer operating mode is state-free, this value has no meaning.
SERVER-OPERATING-MODE attribute
(AppServer only)

Returns the operating mode of the current AppServer session.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

This attribute is valid only if the REMOTE attribute is TRUE.

The possible values for this attribute include:

- "State-reset"
- "State-aware"
- "Stateless"
- "State-free"

This is the value of the operatingMode property set for this AppServer in the ubroker.properties file. For information on how to configure the operating mode for an AppServer instance, see *OpenEdge Application Server: Administration*.

SESSION-END attribute

Sets the end of a logical WebSpeed session. Intended for internal use only.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** WEB-CONTEXT system handle

SESSION-ID attribute

Specifies the user login session ID for the user represented by the Client-principal object. You must set this attribute before you can seal the associated Client-principal object using the SEAL( ) method.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Client-principal object handle

If you specify the Unknown value (?) or the empty string (""), the AVM generates a run-time error.

You can also set this attribute to one of the following values:

- The universally unique identifier (UUID) generated by the GENERATE-UUID function
• The SERVER-CONNECTION-ID attribute, on the SESSION system handle, to map the user ID of the user login session to the connection ID of an AppServer session

Once the Client-principal object is sealed, this attribute is read-only.

See also: SEAL( ) method

SET-ACTOR( ) method

Sets the ACTOR attribute for this SOAP header entry.

Return type: LOGICAL

Applies to: SOAP-header-entryref object handle

Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET-ACTOR( character )</td>
<td>Sets the ACTOR attribute for this SOAP header entry.</td>
</tr>
</tbody>
</table>

character

A character variable containing the URI of the SOAP actor. The actor can be used to indicate the recipient of a SOAP header element.

Call this method once you have associated the XML with a SOAP header entry using the SET-NODE( ) method.

SET-APPL-CONTEXT( ) method

Sets (and records) the application context for the current session in each connected audit-enabled database whose current audit policy has this audit event enabled. Application context provides meaningful information about the conditions under which an application audit event occurred.

This method returns a Base64 character string that specifies the universally unique identifier (UUID) of the primary index for all audit event records generated by this method for this application context. This UUID is recorded in all subsequent audit event records until you either clear this application context or set a different application context. The UUID is 22 characters in length (the two trailing Base64 pad characters are removed).

Return type: CHARACTER

Applies to: AUDIT-CONTROL system handle

Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET-APPL-CONTEXT( event-context [, event-detail [, audit-custom-detail ] ] )</td>
<td>Sets the application context for the current session in each connected audit-enabled database.</td>
</tr>
</tbody>
</table>

event-context

The event-context parameter can include one or more of the following fields:

- event-context
- event-detail
- audit-custom-detail

These fields are optional and can be repeated as necessary. Each field is separated from the next by a comma and space (", ").

event-detail

The event-detail parameter specifies additional details about the event. It can include any number of fields separated by commas, each field having a colon (":") followed by a string.

audit-custom-detail

The audit-custom-detail parameter specifies custom details for the event. It can include any number of fields separated by commas, each field having a colon (":") followed by a string.
**event-context**

A character expression that specifies the context for the audit event. The value of this expression cannot exceed 200 characters. You can also use this value as an alternate index for querying the audit event record.

If you specify the Unknown value (?), the AVM generates a run-time error.

**event-detail**

An optional character expression that specifies additional audit detail. The value of this expression cannot exceed 10,000 characters.

**audit-custom-detail**

An optional character expression that specifies additional user detail. The value of this expression cannot exceed 10,000 characters.

The UUID is saved as the APPL-CONTEXT-ID attribute value for each connected audit-enabled database.

There can be only one active application context per session at any one point in time. To set a different application context for the session, you can:

- Call the CLEAR-APPL-CONTEXT( ) method, to clear the current application context, and then call the SET-APPL-CONTEXT( ) method with the new application context.

- Call the SET-APPL-CONTEXT( ) method with the new application context. If there is an existing application context in effect, the AVM clears the existing application context before setting the new application context.

Calling this method generates an audit event, and creates an audit record for the event in all connected audit-enabled databases according to each database’s current audit policy settings.

The following code fragment illustrates how to use the SET-APPL-CONTEXT( ) method:

```
DEFINE VARIABLE name AS CHARACTER NO-UNDO.
DEFINE VARIABLE id  AS CHARACTER NO-UNDO.

id = AUDIT-CONTROL:SET-APPL-CONTEXT("Payroll app", "fica calculation", name).
.
.
AUDIT-CONTROL:LOG-AUDIT-EVENT(34123, "payroll.fica.calc").
.
.
AUDIT-CONTROL:CLEAR-APPL-CONTEXT.
```

See also: APPL-CONTEXT-ID attribute, CLEAR-APPL-CONTEXT( ) method

**SET-ATTRIBUTE( ) method**

Adds a new attribute to an element. If an attribute with the same name is already present, its value is replaced with the specified value.
**SET-ATTRIBUTE-NODE( ) method**

Associates an XML ATTRIBUTE node with the referenced X-noderef object handle.

**Return type:** LOGICAL

**Applies to:** X-noderef object handle

**Syntax**

```plaintext
SET-ATTRIBUTE-NODE( attr-node-handle )
```

**attr-node-handle**

A valid X-noderef handle that represents an XML ATTRIBUTE node created with the CREATE-NODE-NAMESPACE( ) or CREATE-NODE( ) method.
SET-BLUE-VALUE( ) method

(Graphical interfaces only)

Specifies the blue component of an entry in the color table. You cannot change a static color with this method. Before changing the color, you must make the color dynamic using the SET-DYNAMIC( ) method. For an example, see r-colhan.p in the COLOR-TABLE system handle entry.

**Return type:** LOGICAL
**Applies to:** COLOR-TABLE system handle

**Syntax**

```
SET-BLUE-VALUE ( index , blue-value )
```

*index*

An integer expression that specifies an entry in the color table.

*blue-value*

An integer expression that specifies the blue RGB component of an entry in the color table. The value must be in the range 0 to 255.

If the operation is successful, the method returns TRUE.

---

SET-BREAK( ) method

Sets a breakpoint for a debugging session.

**Return type:** LOGICAL
**Applies to:** DEBUGGER system handle

**Syntax**

```
SET-BREAK ( [ procedure [ , line-number ] ] )
```

*procedure*

A character expression that specifies the name of the procedure in which you want to set the breakpoint. The specified procedure does not have to exist at the time the breakpoint is set. If you do not specify *procedure*, the method sets the breakpoint at the next executable line of the current procedure.

*line-number*

An integer expression that specifies the line number in *procedure* (based at line 1 of the debug listing) where you want to set the breakpoint. A positive integer greater than or equal to 1 represents a line number in the specified *procedure* file. Zero (0) or a negative integer value represents the first executable line of the main procedure block in the specified *procedure* file. If you do not specify *line-number*, the method sets the breakpoint at the first executable line of *procedure* file. If *line-number* is greater than the last executable line number, the method sets the breakpoint at the last executable line of
procedure. If line-number does not specify an executable line, the method sets the breakpoint at the next executable line after the line specified by line-number.

If the Debugger is initialized, this method returns TRUE. Otherwise, it returns FALSE with no effect. For more information, see the reference entry for the DEBUGGER system handle.

Note: To use this method, you must have the Application Debugger installed in your OpenEdge environment.

Note that the Debugger sets breakpoints on physical lines—not statements. If you invoke DEBUGGER:SET-BREAK( ) on a line that contains other executable statements, all the other statements on that line execute before the breakpoint occurs on the next executable line. This is true whether the statements appear on the same line before or after the invocation of the SET-BREAK( ) method.

If you invoke DEBUGGER:SET-BREAK( procedure, line-number ) on the same line that is specified by procedure and line-number, the specified line executes the first time without breaking. The breakpoint occurs only on the second and succeeding executions of the line.

Note: You cannot set a watchpoint programmatically using the DEBUGGER system handle. A watchpoint is a form of breakpoint which tells the Debugger to interrupt program execution when the value of a variable, buffer field, or attribute reference changes.

SET-BUFFERS( ) method

Binds all buffers for a query or dynamic ProDataSet object at the same time. Any buffers previously added to the ProDataSet object are removed.

Use the ADD-BUFFER( ) method to add one buffer to the object, without affecting the other buffers, if any.

Return type: LOGICAL
Applies to: ProDataSet object handle, Query object handle

Syntax

\[
\text{SET-BUFFERS ( buffer }_1 \text{, buffer }_2 \ldots \text{ )}
\]

buffer

A handle to a buffer, or a CHARACTER expression that evaluates to the name of a buffer that the AVM searches for at run time.

The maximum number of buffers per query is 18.

Note: Searching for a buffer using a handle is more efficient than a character expression. The AVM resolves a character expression at run time by searching in the current routine for a static buffer with that name. If not found, the AVM searches the enclosing main procedure. If still not found, the AVM searches up through the...
calling programs of the current routine, and their main procedures. Since a handle
uniquely identifies the buffer, no such search is required.

Following is an example:

```
```

**SET-CALLBACK( ) method**

Associates a method within a class instance, or an internal procedure within a persistent
procedure, with an ABL callback event.

**Return type:** LOGICAL

**Applies to:** Buffer object handle, ProDataSet object handle, Query object handle

**Syntax**

```
SET-CALLBACK ( callback-name, routine-name [, routine-context ] )
```

**callback-name**

A quoted string or character expression representing the name of a callback. The
*callback-name* is not case-sensitive.

**routine-name**

A quoted string or character expression representing the name of a method or an internal
procedure that resides within *routine-context*.

**routine-context**

An object reference for a class instance or a handle to a persistent procedure that contains
the method or internal procedure specified by *routine-name*. If not specified, and the
routine is executed within a procedure, THIS-PROCEDURE is used as the routine context.
If not specified, and the routine is executed within a class instance, THIS-OBJECT is used
as the routine context.

If *callback-name* is not a valid callback, or *routine-context* is not a valid object reference
or handle, this method returns FALSE; otherwise, it returns TRUE. If the SET-CALLBACK( )
method is specified but cannot be invoked, or it fails, no method or procedure is executed as part
of the callback event.

**Note:** If *routine-name* represents a class method that is associated with an ABL event as a
callback, and the method is overridden in a derived class, the overridden method is run
when the callback is invoked.

**SET-CALLBACK-PROCEDURE( ) method**

Associates an internal procedure with an ABL callback event.
**SET-CALLBACK-PROCEDURE( ) method**

**Return type:** LOGICAL

**Applies to:** Buffer object handle, Procedure object handle, ProDataSet object handle, Query object handle

**Syntax**

```
SET-CALLBACK-PROCEDURE (callback-name, internal-procedure [ , procedure-context ])
```

**callback-name**

A quoted string or character expression representing the name of a callback. The *callback-name* is not case-sensitive. For example:

- For Web services, this can be either "REQUEST-HEADER" or "RESPONSE-HEADER". The AVM invokes the internal procedure associated with the “REQUEST HEADER” event as part of an outgoing SOAP request. The request procedure provides access to the SOAP header during the request message. The AVM invokes the internal procedure associated with the “RESPONSE HEADER” callback as part of an incoming SOAP request. The response procedure provides access to the SOAP header during the response message.

- For a ProDataSet object, this can be "BEFORE-FILL" or "AFTER-FILL".

- For a ProDataSet object buffer, this can be "BEFORE-FILL", "AFTER-FILL", "BEFORE-ROW-FILL", "AFTER-ROW-FILL", "ROW-CREATE", "ROW-DELETE", "ROW-UPDATE", "FIND-FAILED", or "SYNCHRONIZE".

- For a query, this can be "OFF-END".

You can also use the APPLY-CALLBACK( ) method to apply a callback procedure for an object.

**internal-procedure**

A quoted string or character expression representing the name of an internal procedure that resides within *procedure-context*.

For Web services, the AVM invokes the specified internal procedure as part of the SOAP request message formulation.

**procedure-context**

A handle to a procedure that contains the internal procedure specified by *internal-procedure*. If not specified, THIS-PROCEDURE is used as the procedure context.

This method returns FALSE if the *callback-name* is not valid or if *procedure-context* is not a valid handle; returns TRUE otherwise. If this method is specified but cannot be invoked, or it fails, no procedure will be executed as part of the callback event.

If this method is called multiple times, the new values passed replace the previously set values.
To remove the callback procedure associated with a Web service procedure, invoke this method with a valid callback-name and an empty string, "", for the internal-procedure. The AVM will not generate an error if an attempt is made to remove a callback procedure and a callback is not associated with the callback.

For more information on events, see the “Handle-based Object Events Reference” section on page 1827.

See also: APPLY-CALLBACK( ) method, GET-CALLBACK-PROC-CONTEXT( ) method, GET-CALLBACK-PROC-NAME( ) method

SET-CLIENT( ) method

Uses the user ID associated with a sealed Client-principal object to set the default user ID for the ABL session, and attempts to set the user ID on all connected OpenEdge databases (that do not already have a user ID explicitly set).

Note: If the user ID on one or more connected databases has already been set, by either the SETUSERID or SET-DB-CLIENT functions, the user ID specified by this method is ignored and no attempt is made to reset the user ID on those particular databases. Also, any subsequent calls to either the SETUSERID or SET-DB-CLIENT functions will override the database user ID set by this method.

When a user ID is set on a connected database, the AVM uses that user ID to determine whether the user has permission to access tables and fields in that particular database.

Return type: LOGICAL

Applies to: SECURITY-POLICY system handle

Syntax

```
SET-CLIENT( client-principal-handle )
```

client-principal-handle

A handle to a sealed Client-principal object. The Client-principal object must be created in an authentication domain that is registered in the application’s trusted authentication domain registry. If the Client-principal object is not sealed, or the handle is the Unknown value (?), the AVM generates a run-time error and the current application’s user ID remains unchanged.

If the LOGIN-STATE attribute for the sealed Client-principal object is not "LOGIN", the AVM generates a run-time error and the current user ID remains unchanged.

If successful, this method returns TRUE. Otherwise, it returns FALSE.

When a user ID is set for an application, and at least one connected audit-enabled database, this method generates an audit event and creates an audit record for the event in all connected audit-enabled databases on which it was set according to each database’s current audit policy settings.
You can use this method, instead of the SETUSERID function or the SET-DB-CLIENT function, to set a database user ID when the user ID is not in the _User table. You can also use the SETUSERID function or the SET-DB-CLIENT function to override the user ID set by this method for one or more connected databases.

See also: Client-principal object handle, SET-DB-CLIENT function, SETUSERID function

SET-COMMIT( ) method
(AppServer only)

Directs the transaction object to commit the transaction when the AppServer session completes the current request and returns execution to the client.

Return type: LOGICAL

Applies to: Transaction object handle

Syntax

```
SET-COMMIT()
```

If the operation is successful, the method returns TRUE. If a transaction initiating procedure is not active in the current AppServer session, this method returns FALSE. You also cannot invoke this method after prior invocation of a SET-ROLLBACK( ) method during service of the same client request.

SET-CONNECT-PROCEDURE( ) method

Identifies the name of the procedure that is invoked when a CONNECT event occurs.

Return type: LOGICAL

Applies to: Server socket object handle

Syntax

```
SET-CONNECT-PROCEDURE( event-internal-procedure [ , procedure-context ] )
```

**event-internal-procedure**

A quoted string or character expression representing the name of an internal procedure that resides within procedure-context. When a client has requested a connection to this port, the specified internal procedure is called.

**procedure-context**

A handle to a procedure that contains the internal procedure specified by event-internal-procedure. If not specified, THIS-PROCEDURE is used as the procedure-context.
SET-DYNAMIC( ) method

Returns FALSE if procedure-context is not a valid handle, returns TRUE otherwise. If this method is not invoked, or if it fails, no connection procedure will be executed when the CONNECT event occurs.

For more information on connecting sockets, see OpenEdge Development: Programming Interfaces.

SET-DYNAMIC( ) method
(Graphical interfaces only)

Sets a color entry to a dynamic or static color.

Return type: LOGICAL
Applies to: COLOR-TABLE system handle

Syntax

```
SET-DYNAMIC ( index , logical-expr )
```

`index`

An integer expression that specifies an entry in the color table.

`logical-expr`

A logical expression that specifies the dynamic status of an entry in the color table.

If `logical-expr` is TRUE and sets the entry to a static color if `logical-expr` is FALSE. If the operation is successful, the method returns TRUE.

SET-GREEN-VALUE( ) method
(Graphical interfaces only)

Specifies the green component of an entry in the color table. If the operation is successful, the method returns TRUE.

You cannot change a static color with this method. Before changing the color, you must make the color dynamic using the SET-DYNAMIC( ) method. For an example, see r-colhan.p in the COLOR-TABLE system handle entry.

Return type: LOGICAL
Applies to: COLOR-TABLE system handle

Syntax

```
SET-GREEN-VALUE ( index , green-value )
```

`index`

An integer expression that specifies an entry in the color table.
**SET-INPUT-SOURCE( ) method**

Specifies the source of XML text to be parsed by a SAX-reader object.

**Return type:** LOGICAL  
**Applies to:** SAX-reader object handle

**Syntax**

```
SET-INPUT-SOURCE ( mode, { file | memptr | handle | longchar } )
```

**mode**

A CHARACTER expression evaluating to “FILE”, “MEMPTR”, “HANDLE”, or “LONGCHAR” indicating whether the XML source is a file, a MEMPTR, a WEB-CONTEXT system handle, or a LONGCHAR variable.

**file**

A CHARACTER expression that indicates the name of a file that contains the source XML text. This can be a relative path name, an absolute path name, or an HTTP URL. Any relative path name is relative to the current working directory.

**memptr**

A MEMPTR variable that contains the source XML text. The size of the MEMPTR variable must match the size of the XML text.

**handle**

A WEB-CONTEXT system handle. In a WebSpeed application, this directs SAX-reader to get the XML source from WEB-CONTEXT.

**longchar**

A LONGCHAR variable that contains the source XML text. The size of the LONGCHAR variable must match the size of the XML text.

The following checks are not performed by SET-INPUT-SOURCE( ) but are performed by SAX-PARSE( ) at run time:

- Whether or not a file exists and is accessible
- Whether or not a MEMPTR is usable
- Whether or not WEB-CONTEXT’s XML attribute is YES

If WEB-CONTEXT is used outside of a WebSpeed environment, the AVM raises a run-time error.
SET-MUST-UNDERSTAND( ) method

Sets the MUST-UNDERSTAND attribute for this SOAP header entry.

Return type: LOGICAL
Applies to: SOAP-header-entryref object handle

Syntax

\[
\text{SET-MUST-UNDERSTAND ( logical )}
\]

\( \text{logical} \)

A logical variable containing the value of the MUST-UNDERSTAND attribute.

Call this method once you have associated the XML with a SOAP header entry using the SET-NODE( ) method.

SET-NODE( ) method

Replaces the underlying XML of a SOAP-header-entryref object with the DOM XML sub-tree rooted by the X-noderef object.

Return type: LOGICAL
Applies to: SOAP-header-entryref object handle

Syntax

\[
\text{SET-NODE ( x-noderef )}
\]

\( \text{x-noderef} \)

A variable of type X-noderef that refers to the XML that will become the SOAP-header-entryref object.

The supplied X-noderef object corresponds to the SOAP header entry element. The method performs a deep copy of the X-noderef object and its sub-tree and adds namespace declarations to the SOAP-header-entryref as necessary. For example, if the X-noderef object uses a namespace that is declared in its parent tree by an ancestor of the X-noderef object, that namespace declaration is carried over to the SOAP-header-entryref object.

Care must be taken to distinguish between a SOAP header entry and how it is represented in ABL. A SOAP header is represented by the SOAP-header object. A SOAP header entry is represented by a SOAP-header-entryref object. The SOAP-header object maintains a list of pointers to existing SOAP-header-entryref objects that have been explicitly associated with the SOAP-header object by calling its ADD-HEADER-ENTRY( ) method.

Before you can use the SET-NODE( ) method on the SOAP-header-entryref object, it must be associated with its SOAP-header object. Call the SOAP-header object’s ADD-HEADER-ENTRY( ) method prior to calling the SET-NODE method( ) or the SET-SERIALIZED method( ) for the first time. Otherwise, you will get a run-time error.
If you call either the SET-NODE( ) or SET-SERIALIZED( ) method twice in a row with the same SOAP-header-entryref, the second call will overwrite the underlying SOAP header entry created by the first call. Although you can use the same SOAP-header-entryref object to create more than one SOAP header entry, you need to call the ADD-HEADER-ENTRY() method between calls to these methods to create a new entry on the SOAP-header object’s list and associate the new entry with the current content of the SOAP-header-entryref object.

SET-NUMERIC-FORMAT( ) method

Sets the NUMERIC-SEPARATOR and NUMERIC-DECIMAL-POINT attributes simultaneously.

Return type:  LOGICAL
Applies to:  SESSION system handle

Syntax

```
SET-NUMERIC-FORMAT ( separator , decimal-point )
```

* **separator**

A CHARACTER expression that represents, in formatted text, a number’s thousands separator.

The thousands separator cannot be represented by any of the following:

- The characters B C D R Z z 0 1 2 3 4 5 6 7 8 9 + - <> ( ) *

  **Note:** The space character is allowed.

- Any multi-byte character

* **decimal-point**

A CHARACTER expression that represents, in formatted text, a number’s decimal point.

The decimal point cannot be represented by any of the following:

- The characters B C D R Z z 0 1 2 3 4 5 6 7 8 9 + - <> ( ) *

- The space character

- Any multi-byte character

SET-NUMERIC-FORMAT( ) returns TRUE if the operation is successful.

**Note:** The values set by the SET-NUMERIC-FORMAT( ) method override the values set by the Thousands Separator (-numsep) and Fractional Separator (-numdec) startup parameters.
SET-OUTPUT-DESTINATION( ) method

Specifies the target for an XML document that a SAX-writer object creates.

**Return type:** LOGICAL  
**Applies to:** SAX-writer object handle

**Syntax**

```plaintext
SET-OUTPUT-DESTINATION ( mode, { file | stream | stream-handle | memptr | longchar } )
```

**mode**

A character expression that evaluates to one of the following: “FILE”, “STREAM”, “STREAM-HANDLE”, “MEMPTR”, or “LONGCHAR”. The mode indicates whether the XML target is a file, a stream, a MEMPTR, or a LONGCHAR variable.

**file**

A CHARACTER expression that indicates the name of a file to which the XML document is to be written. This can be a relative pathname, an absolute pathname, or an HTTP URL. Any relative pathname is relative to the current working directory.

**stream**

A character expression that represents the name of an ABL stream. If stream is “”, the AVM saves the document to the unnamed stream of the ABL session.

**stream-handle**

A character expression that represents a stream object handle.

**memptr**

A MEMPTR variable to which the XML document is to be written. The MEMPTR will be overwritten and the new size of the MEMPTR variable will match the size of the XML text.

**longchar**

A LONGCHAR variable to which the XML document is to be written. The LONGCHAR will be overwritten and the new size of the LONGCHAR variable will match the size of the XML text.

When writing an XML document to a LONGCHAR variable, the AVM writes the LONGCHAR variable in the code page of the XML document as determined by the XML document’s ENCODING attribute. If the ENCODING attribute is not set, the LONGCHAR variable is saved in UTF-8.

If the LONGCHAR variable’s code page is fixed (that is, set using the FIX-CODEPAGE statement), the code page must be equivalent to the encoding specified in the XML document’s ENCODING attribute. If not, the START-DOCUMENT( ) method returns an error and the XML document is not saved to the LONGCHAR variable.
Use this method to set the output destination, which is where the object will write the XML document. This method must be called before you call any of the writing methods or they will raise errors. You can only call this method when the object’s WRITE-STATUS property is SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. In other words, you cannot set a new output destination while the SAX-writer object is currently writing XML. This method fails and generates an error message if it is called while writing.

The SET-OUTPUT-DESTINATION method does not check if the specified destination is valid. If does not check whether a MEMPTR or LONGCHAR variable is usable, and it does not check whether a file location or stream is accessible. This destination is checked at run time by the START-DOCUMENT method.

When writing to a MEMPTR or LONGCHAR, the method deletes the previous contents and allocates new memory. For example, writing to a MEMPTR is the logical equivalent of using SET-SIZE based upon the document size after calling END-DOCUMENT. This is the same way that the X-document object handles memory.

**SET-PARAMETER( ) method (Handle)**

Lets you set parameters for one of the following:

- A procedure or user-defined function you want to invoke dynamically
- A Windows DLL routine or UNIX shared library routine you want to invoke dynamically
- An attribute you want to get or set dynamically
- A method you want to invoke dynamically

**Return type:** LOGICAL  
**Applies to:** Call object handle  
**Syntax**

```
SET-PARAMETER(parameter-number, data-type, iomode, parameter-value)
```

*parameter-number*

An integer expression indicating the order of the parameter. Use 1 for the first parameter, 2 for the second parameter, and so on.

*data-type*

A CHARACTER expression indicating the data type of the parameter and evaluating to one of the following:

- "CHARACTER"
- "DATASET-HANDLE"
- "DATE"
- "DATETIME"
SET-PARAMETER( ) method (Handle)

- "DATETIME-TZ"
- "DECIMAL"
- "HANDLE"
- "INT64"
- "INTEGER"
- "LOGICAL"
- "LONGCHAR"
- "MEMPTR"
- "RAW"
- "ROWID"
- "TABLE-HANDLE"

TABLE-HANDLE can be a handle to a static or dynamic temp-table. Likewise, DATASET-HANDLE can be a handle to a static or dynamic ProDataSet object.

**Note:** To manage BUFFER parameters, use HANDLE parameters.

For each parameter, the data type specified by the caller and the callee must be compatible. For example, an ABL application must specify a 64-bit ABL data type (INT64) when calling a DLL routine that expects a 64-bit signed integer. The ABL program cannot declare the ABL variable as LONG or UNSIGNED-LONG and expect the correct behavior. Similarly, if a DLL routine expects a 32-bit value, the ABL program must specify a 32-bit ABL data type (LONG or UNSIGNED-LONG). The ABL program cannot declare the ABL variable as a SHORT or UNSIGNED-SHORT and expect the correct behavior.

When invoking a Windows DLL or UNIX shared library function, ABL DLL data types are valid as `data-type` values. `data-type` specifies the type expected by the DLL or shared library routine parameter. For example, the parameter `data-type` is set to "LONG" if the DLL routine parameter expects "LONG". For a list of valid ABL DLL data types, see the “DEFINE PARAMETER statement” section on page 365.

If a DLL data type is specified for a non-DLL invocation, the AVM raises a run-time error.

**Note:** If you pass an ABL character string to a UNIX shared library routine, you can pass it as a CHARACTER variable or expression. However, if you expect the shared library routine to modify the value, Progress Software Corporation recommends that you pass a MEMPTR containing a null-terminated character string.

**iomode**

A CHARACTER expression indicating the mode of the parameter and evaluating to one of the following:

- "INPUT"
• "OUTPUT"
• "INPUT-OUTPUT"
• "OUTPUT-APPEND"

For each parameter, the mode specified by the caller and the callee must match.

For parameters of attributes, specify "INPUT".

For TABLE-HANDLE output parameters whose output is to be appended to the table, and in no other case, specify "OUTPUT-APPEND".

If \texttt{data-type} is "DATASET-HANDLE" or "TABLE-HANDLE", you can append "-by-reference" to any previously listed \texttt{iomode}.

\texttt{parameter-value}

An expression whose type is compatible with \texttt{data-type}.

The \texttt{parameter-value} argument may represent a determinate or indeterminate array. However, you cannot pass an array by value. You can pass an array only as a variable defined using the \texttt{DEFINE VARIABLE} statement with the \texttt{EXTENT} option. If you include the \texttt{EXTENT} keyword in the \texttt{data-type} argument, the AVM ignores it. If you include the array element values in the \texttt{parameter-value} argument, ABL generates a compile error.

If iomode is "INPUT" or "INPUT-OUTPUT", if the data type of \texttt{parameter-value} does not agree with the data type passed, \texttt{parameter-value} will automatically be converted to the data type passed during \texttt{SET-PARAMETER( )} processing.

If iomode is "OUTPUT" or "INPUT-OUTPUT", each of the following must be true:

• \texttt{parameter-value} must represent a program variable or a NO-UNDO TEMP-TABLE field (perhaps with an array reference).

• \texttt{parameter-value} must still be in scope and must still be valid when the dynamic invoke is executed.

If the output value from the called procedure does not have a data type that matches the data type passed, the output value will be converted to the data type passed.

If iomode is "OUTPUT", \texttt{parameter-value} is ignored if the ASYNCHRONOUS attribute is TRUE.

\textbf{SET-PROPERTY( ) method}

Sets the value of the specified application-defined property associated with an unsealed Client-principal object.
SET-READ-RESPONSE-PROCEDURE( ) method

Specifies the name of the procedure to invoke when a READ-RESPONSE event occurs.
**SET-READ-RESPONSE-PROCEDURE( ) method**

**Return type:** LOGICAL  
**Applies to:** Socket object handle

**Syntax**

```plaintext
SET-READ-RESPONSE-PROCEDURE( event-internal-procedure [, procedure-context ] )
```

*event-internal-procedure*

A quoted string or character expression representing the name of an internal procedure that resides within `procedure-context`. When data is available on the socket, the specified internal procedure is called. If not specified, then no read procedure will be executed when the READ-RESPONSE event occurs.

*procedure-context*

A handle to a procedure that contains the internal procedure specified by `event-internal-procedure`. If not specified, THIS-PROCEDURE is used as the `procedure-context`.

**Note:** Returns FALSE if the `procedure-context` is not a valid handle; returns TRUE otherwise. If this method is not invoked, or it fails, no read procedure will be executed when the READ event occurs.

---

**SET-RED-VALUE( ) method**  
*(Graphical interfaces only)*

Specifies the red component of an entry in the color table. You cannot change a static color with this method. Before changing the color, you must make the color dynamic using the SET-DYNAMIC( ) method. For an example, see `r-colhan.p` in the COLOR-TABLE system handle entry.

**Return type:** LOGICAL  
**Applies to:** COLOR-TABLE system handle

**Syntax**

```plaintext
SET-RED-VALUE( index , red-value )
```

*index*

An integer expression that specifies an entry in the color table.

*red-value*

An integer expression that specifies the red RGB component of an entry in the color table. The value must be in the range 0 to 255.

If the operation is successful, the method returns TRUE.
**SET-REPOSITIONED-ROW( ) method**

Sets the row index where records positioned with the REPOSITION TO ROWID (or RECID) statement are displayed.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
SET-REPOSITIONED-ROW ( n , "ALWAYS" | "CONDITIONAL" )
```

- **n**
  
  Indicates the row number where the new record is displayed, 1 being the first row.

- **"ALWAYS"**
  
  Specifies that the REPOSITION TO ROWID statement always uses the indicated row number. If all of the records in a result set fit in the browse viewport, the REPOSITION statement only moves focus to the existing row.

- **"CONDITIONAL"**
  
  Specifies that the REPOSITION TO ROWID statement uses the indicated row number unless the new row is already in the browse viewport. In this case, the REPOSITION statement moves focus to the existing row.

By default, this is the top row in the browse viewport (index 1). If the associated query is defined with the INDEXED-REPOSITION option, the CONDITIONAL option is ignored.

**SET-RGB-VALUE( ) method**  
**Graphical interfaces only**

Specifies a combination of the red, green, and blue values of an entry in the color table. You cannot change a static color with this method. Before changing the color, you must make the color dynamic using the SET-DYNAMIC( ) method. For an example, see r-colhan.1 in the COLOR-TABLE system handle entry.

**Return type:** LOGICAL  
**Applies to:** COLOR-TABLE system handle

**Syntax**

```
SET-RGB-VALUE ( index , integer-expression )
```

- **index**
  
  An integer expression that specifies an entry in the color table.
**SET-ROLLBACK( ) method**

(AppServer only)

Directs the transaction object to rollback the transaction when the AppServer session completes the current request and returns execution to the client.

**Return type:**  LOGICAL

**Applies to:**  Transaction object handle

**Syntax**

```
SET-ROLLBACK ( )
```

If the operation is successful, the method returns TRUE. If a transaction initiating procedure is not active in the current AppServer session, this method returns FALSE. You also can invoke this method after prior invocation of a SET-COMMIT( ) method during service of the same client request.

---

**SET-SELECTION( ) method**

Selects (and highlights) the text in a widget between two specified character offsets.

**Return type:**  LOGICAL

**Applies to:**  BROWSE widget (column), COMBO-BOX widget, EDITOR widget, FILL-IN widget

**Syntax**

```
SET-SELECTION ( start-pos , end-pos )
```

**start-pos**

An integer expression that specifies the offset of the first character to be selected.

**end-pos**

An integer expression that specifies the offset of the first character after the selection.

This method selects the text that begins at the offset start-pos and ends at the offset end-pos. If the operation is successful, the method returns TRUE. Otherwise, it returns FALSE.
SET-SERIALIZED( ) method

Sets the SOAP-header-entryref object’s underlying XML from serialized XML.

**Return type:** LOGICAL

**Applies to:** SOAP-header-entryref object handle

**Syntax**

```
SET-SERIALIZED ( longchar )
```

<table>
<thead>
<tr>
<th>longchar</th>
</tr>
</thead>
<tbody>
<tr>
<td>A variable of type LONGCHAR that contains the serialized XML that will become the SOAP-header-entryref object.</td>
</tr>
</tbody>
</table>

Functions the same as SET-NODE( ), except it expects a LONGCHAR whose contents is equivalent to the serialized form of the X-noderef that would be passed to the SET-NODE( ) method. No validation is done by this method. If the contents of the LONGCHAR is not valid for the SOAP message, an error might be raised when the SOAP message is processed. If the LONGCHAR is empty, or the caller passes the Unknown value (?), the header entry will be removed from the SOAP message.

Care must be taken to distinguish between a SOAP header entry and how it is represented in ABL. A SOAP header is represented by the SOAP-header object. A SOAP header entry is represented by a SOAP-header-entryref object. The SOAP-header object maintains a list of pointers to existing SOAP-header-entryref objects that have been explicitly associated with the SOAP-header object by calling its ADD-HEADER-ENTRY( ) method.

Before you can use the SET-SERIALIZED( ) method on the SOAP-header entryref object, it must be associated with its SOAP-header object. Call the SOAP-header object’s ADD-HEADER-ENTRY( ) method prior to calling the SET-SERIALIZED method( ) or the SET-NODE method( ) for the first time. Otherwise, you will get a run-time error.

If you call either the SET-SERIALIZED( ) or SET-NODE( ) method twice in a row with the same SOAP-header-entryref, the second call will overwrite the underlying SOAP header entry created by the first call. Although you can use the same SOAP-header-entryref object to create more than one SOAP header entry, you need to call the ADD-HEADER-ENTRY() method between calls to these methods to create a new entry on the SOAP-header object’s list and associate the new entry with the current content of the SOAP-header-entryref object.

---

**Note:** This operation produces a different result depending on the platform. In Windows GUI platforms, ABL measures character offset positions between characters. On non-Windows GUI or character platforms, ABL measures character offset positions on characters.

In Windows, both the regular editor and the large editor support SET-SELECTION.

For browses, this method applies only to fill-in and combo-box browse columns.
SET-SOCKET-OPTION( ) method

Sets the specified socket option. TCP supports a number of socket options. Please refer to TCP documentation for a description of these options.

**Return type:** LOGICAL  
**Applies to:** Socket object handle

**Syntax**

```plaintext
SET-SOCKET-OPTION( name, arguments )
```

**name**

A character expression which indicates the name of the socket option to be set.

**arguments**

A character expression that contains a comma separated list of arguments specific for the option.

Table 104 describes the options ABL supports.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP-NODELAY</td>
<td>An enable indicator, which is either TRUE or FALSE.</td>
</tr>
</tbody>
</table>
| SO-LINGER       | Two comma separated values:  
|                 | • The onoff indicator, which is either TRUE or FALSE.  
|                 | • The linger time. If the onoff indicator is FALSE, the linger time does not need to be provided. |
| SO-KEEPALIVE    | Sets the TCP socket option SO_KEEPALIVE.  
|                 | Set arguments to TRUE to turn this option on or to FALSE to turn it off.    |
| SO-REUSEADDR    | Sets the TCP socket option SO_REUSEADDR.  
|                 | Set arguments to TRUE to turn this option on or to FALSE to turn it off.    |
The SET-SOCKET-OPTION( ) method returns TRUE if setting the option succeeded and returns FALSE otherwise. An error can occur if:

- name is not an ABL supported socket option
- The arguments supplied for the option are not valid
- The SET-SOCKET-OPTION( ) operation fails

### SET-SORT-ARROW( ) method

Sets the sort-arrow indicator and, optionally, the sort-level number for a browse column.

**Return type:** LOGICAL  
**Applies to:** BROWSE widget

**Syntax**

```
SET-SORT-ARROW ( column-index, ascending [, n ] )
```

- **column-index**
  
  An INTEGER expression that specifies the column for which the sort-arrow indicator is set. If the column does not exist, the AVM generates a run-time error.

- **ascending**
  
  A LOGICAL expression where TRUE indicates ascending sort order, and FALSE indicates descending sort order.
Set to the Unknown value (?) to remove a sort-arrow indicator that was previously set for this column. Use the CLEAR-SORT-ARROWS( ) method to clear sort-arrow indicators for all columns in the browse.

An optional INTEGER expression that specifies the sort level to display at the right of the sort arrow in the column label. Valid values are 1 through 9, inclusive, and the Unknown value (?). If you do not specify a value, or you specify the Unknown value (?), a sort-level number does not appear in the column label. If you specify an invalid value, the AVM generates a run-time error.

You can set two or more columns in a browse to the same sort-level number, and you can leave gaps in the sequence. This allows for rearranging values, as necessary.

The sort-arrow indicator, which consists of an arrow bitmap pointing upward to indicate ascending sort order and pointing downward to indicate descending sort order, is displayed with the column label. It appears at the immediate right of the column label, whether the label is right-justified or left-justified.

The optional sort-level number, if specified, indicates multi-level sorting and appears at the right of the sort arrow in the column label. For example, you can set the sort-level number to show that data in one column of a browse has first been sorted in ascending order and data in another column has then been sorted in descending order.

**Note:** Setting a sort-arrow indicator and sort-level number on a column does not change the column’s sort order or the browse’s query. The browse’s query is responsible for actually sorting the data.

You can set a sort-arrow indicator and a sort-level number on a browse column before or after the browse widget is realized. Calling this method does not realize the widget.

If the column label text is too wide for the column, the AVM displays as much of the label as possible and clips the rest of the text. If there is no space in the column label to display the sort-arrow indicator, the AVM will not make the column wider at run time; consider increasing the width of the column.

If the browse has one or more stacked column labels, the sort-arrow indicators appear centered vertically within the label header. Note that the sort-arrow indicators are positioned based on the overall height of the label header, not based on the height of any individual column label.

In character interfaces, the ascending sort-arrow indicator is represented by the caret (0x5E) and the descending indicator is represented by the lower case “v” (0x76). These characters are not configurable. The sort-arrow indicator appears at the far right of the column label. This minimizes the chance of the user misreading the arrow as part of the column label. If the column label text is too wide for the column, the AVM displays as much of the label as possible and clips the rest of the text. If the browse has one or more stacked column labels, the sort-arrow indicators appear on the top row of the label header.

If successful, this method returns TRUE. Otherwise, it returns FALSE.
**SET-WAIT-STATE( ) method**

Sets or cancels an ABL wait state that blocks user and system input.

**Return type:** LOGICAL  
**Applies to:** SESSION system handle

**Syntax**

```
SET-WAIT-STATE ( state-string )
```

*state-string*

A character-string expression that sets the wait state.

The value of *state-string* determines the wait state and the type of wait cursor displayed. The valid values are:

- "GENERAL" — Displays the system-busy cursor
- "COMPILER" — Displays the ABL compiler cursor

Input is blocked and the wait cursor is displayed until the wait state is cancelled. The null string ("") cancels the wait state.

The SET-WAIT-STATE( ) method accepts an arbitrary mouse pointer name (any string which is a valid argument to the LOAD-MOUSE-POINTER( ) method) as an argument, in addition to the "GENERAL", "COMPILER", and "" states. The return value is TRUE if the wait-state is set successfully; otherwise the return value is FALSE.

Note that this method is intended to provide user feedback for lengthy processing that involves no user input, such as compiling procedures, doing a time consuming database lookup, or some long CPU and memory operation like computing the value of \( \pi \).

This method is not supported in character mode.

If an error occurs from this method, the AVM displays the error and terminates the wait state.

**Caution:** Be sure that the processing you invoke after setting the wait state is guaranteed to cancel the wait state. Otherwise, the AVM remains in the wait state indefinitely. For example, do not place user input statements, such as SET or UPDATE, between the setting and cancelling of the wait state. Because the user cannot respond to these statements during the wait state, ABL I/O blocks indefinitely, preventing the wait state from being cancelled.
**SHOW-IN-TASKBAR attribute**

*Windows only*

Determines whether an icon for the window appears in the taskbar and in the task-switching window displayed when **ALT+TAB** is pressed.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** WINDOW widget

Applications that display several windows might want only the main window to have an icon on the taskbar.

This attribute defaults to TRUE. If SMALL-TITLE is set to TRUE, the SHOW-IN-TASKBAR attribute will be set to FALSE because, in general, a tool palette should not have an icon in the taskbar. You can override this behavior by setting the SHOW-IN-TASKBAR attribute to TRUE after setting the SMALL-TITLE attribute to TRUE.

If a window that does not appear in the taskbar is minimized, Windows shrinks the window so only the title bar is visible. Windows displays the window at the bottom of the screen. This is standard behavior, but might be unexpected to people who are used to finding minimized windows in the taskbar.

The SHOW-IN-TASKBAR attribute must be set before the window is realized.

The Windows taskbar (through a user property setting) can direct that all minimized windows from the same application be grouped under one taskbar icon. However, the icons for ABL windows whose SHOW-IN-TASKBAR attribute you set to TRUE always appear individually on the taskbar, regardless of taskbar property settings, because ABL does not support this window grouping feature of the taskbar.

.NET forms also have a ShowInTaskbar property (provided by the Progress.Windows.Form class in OpenEdge) that corresponds to the SHOW-IN-TASKBAR window attribute. However, .NET forms typically do conform to the taskbar window grouping setting and might well do so when combined with ABL windows in an ABL session, subject to control by the operating system.

---

**SIDE-LABEL-HANDLE attribute**

A handle to the side label of a widget.
SIDE-LABELS attribute

Indicates whether a frame displays labels to the left of each field.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: FRAME widget

The SIDE-LABELS attribute returns TRUE if the frame displays labels to the left of each field rather than above each field.

SKIP-DELETED-RECORD attribute

Indicates whether the AVM should skip deleted records when accessing a dynamic query’s result list.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: Query object handle

SMALL-ICON attribute

Returns the name of the icon loaded by LOAD-SMALL-ICON().

Data type: CHARACTER
Access: Readable
Applies to: WINDOW widget

SMALL-TITLE attribute

Indicates whether the window has a palette-style title bar.
This title bar is shorter than a normal Windows title bar, and is commonly used for tool palettes (such as in the AppBuilder) and other auxiliary windows. Windows with small title bars do not have maximize or minimize buttons; they only have close buttons.

The MIN-BUTTON and MAX-BUTTON attributes have no effect on a window with a small title bar and are ignored. The CONTROL-BOX attribute specifies whether the window has a close button and system menu (available by right-clicking on the title bar or by pressing ALT+SPACE).

The SMALL-TITLE attribute must be set before the window is realized. The default value of SMALL-TITLE is FALSE.

SOAP-FAULT-ACTOR attribute

The URI of the Web service actor that caused this SOAP fault.

- **Data type:** CHARACTER
- **Access:** Readable
- **Applies to:** SOAP-fault object handle

SOAP-FAULT-CODE attribute

Identifies the SOAP fault code for this SOAP-fault object.

- **Data type:** CHARACTER
- **Access:** Readable
- **Applies to:** SOAP-fault object handle

SOAP-FAULT-DETAIL attribute

Returns the handle of the SOAP fault detail information associated with this SOAP-fault object.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:** SOAP-fault object handle

SOAP-FAULT-STRING attribute

Returns the SOAP fault string describing the fault for this SOAP-fault object.
### SORT attribute

Indicates whether to sort new additions to the item list of a widget.

- **Data type:** LOGICAL  
- **Access:** Readable/Writeable  
- **Applies to:** BROWSE widget (column), COMBO-BOX widget, SELECTION-LIST widget

If the SORT attribute is TRUE, all items added to a combo box or selection list are added in sorted order. This means that the methods ADD-FIRST() and ADD-LAST() add items to the list in sorted order. The setting of this attribute has no affect on the function of the INSERT() and REPLACE() methods. Setting this attribute to FALSE returns these methods to their native function.

For browses, this attribute applies only to combo-box browse columns.

### SORT-ASCENDING attribute

Indicates the sort order for a browse column.

- **Data type:** LOGICAL  
- **Access:** Readable/Writeable  
- **Applies to:** BROWSE widget (column)

When TRUE, the sort-arrow indicates that the column is sorted in ascending order. When FALSE, the sort-arrow indicates that the column is sorted in descending order. When the Unknown value (?), the column sort order is not indicated.

- **Note:** Setting a sort-arrow indicator and sort-level number on a column does not change the column’s sort order or the browse’s query. The browse’s query is responsible for actually sorting the data.

- **See also:** SORT-NUMBER attribute

### SORT-NUMBER attribute

Indicates the sort-level number for a browse column.
SSL-SERVER-NAME attribute

The name of the server for the current Secure Sockets Layer (SSL) session.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** Server object handle, Socket object handle

For the AppServer or a socket object, this is the digital certificate subject name of the server for the current SSL session. It enables you to distinguish between the physical host name and the authenticated SSL server name.

For Web services, this is the digital certificate subject name of the -SOAP\_Endpoint (which is the URL identifying the endpoint for the Web service, not the server providing the WSDL).

When there is no socket connection, or the socket connection is not an SSL-based connection, the default value is the Unknown value (?).

STANDALONE attribute

Determines the value of the standalone string in the XML declaration of a SAX-writer object.

**Data type:** LOGICAL

**Access:** Readable/Writable

**Applies to:** SAX-writer object handle

You can set the attribute to the value of the standalone string in the XML declaration. The default value is the Unknown value (?). If the value is the Unknown value (?), then the standalone string will not appear in the XML declaration.

Valid values of standalone in the XML declaration are “yes” and “no”. If you set the standalone value, then the standalone string appears in the XML declaration.

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
```
This attribute can be read at all times, but can only be written when the WRITE-STATUS is either SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. That is, it can only be changed when the writer is not writing, otherwise it will fail and generate an error message.

---

**START-DOCUMENT( ) method**

Creates the XML document with the prolog information.

**Note:** You must call the SET-OUTPUT-DESTINATION( ) method to set the output destination for the XML document before invoking this method.

**Return type:** LOGICAL

**Applies to:** SAX-writer object handle

**Syntax**

```
START-DOCUMENT()
```

You must call this method to start the output before you call any other writing methods or none of the writing methods will succeed. After you call START-DOCUMENT, the WRITE-STATUS is changed to SAX-WRITE-BEGIN. If START-DOCUMENT is called while the SAX-writer is already writing (that is, with a status other than SAX-WRITE-IDLE or SAX-WRITE-COMPLETE), then the method fails.

If the SAX-writer is unable to write to the output destination, it generates an error message and change the WRITE-STATUS to SAX-WRITE-ERROR.

If the FRAGMENT attribute is FALSE, then the XML declaration is created. The version, encoding style, and standalone state of the document is specified in the declaration. If the ENCODING attribute is not set, the declaration defaults to UTF-8, but this value does not appear in the declaration. If the VERSION attribute is not set, it defaults to “1.0”. If the STANDALONE attribute is not set, then the declaration default is to omit the attribute. Here is the default declaration:

```
<?xml version="1.0"/>
```

**See also:** END-DOCUMENT( ) method, SET-OUTPUT-DESTINATION( ) method

---

**START-ELEMENT( ) method**

Starts an XML node based upon the name of the node in a SAX-writer object.

**Return type:** LOGICAL

**Applies to:** SAX-writer object handle

**Syntax**

```
START-ELEMENT( name [, namespace-URI ] [, SAX-attributes-handle ] )
```

---
**name**

A CHARACTER or LONGCHAR expression evaluating to the fully qualified or unqualified name of the element.

**namespace-URI**

A CHARACTER or LONGCHAR evaluating to the URI of the element, or an empty string (""") or the Unknown value (?) if the element doesn’t contain a namespace. If the handle is the Unknown value (?), then no attributes are added. If the handle is not valid or not a SAX-attributes object, then the method fails and returns FALSE.

**SAX-attributes-handle**

A HANDLE to a SAX-attributes object. The attributes in the SAX-attributes object are added to the new XML element.

Starts an XML node. This method call changes the WRITE-STATUS to SAX-WRITE-TAG.

For every call of the START-ELEMENT() method, there must be a following corresponding call of the END-ELEMENT() method. All the parameter values from the two calls must match for the methods to correspond.

If namespace-URI is present, then the prefix will be resolved in the following order:

1. The method attempts to extract the namespace from the name.

2. The method attempts to extract the namespace from a previously declared namespace.

3. The method attempts to generate the default namespace.

If the name contains a prefix, namespace-URI is present, and this is the first instance of the namespace-URI, then the namespace is added to the element. This technique is equivalent to calling the DECLARE-NAMESPACE() method.

If only the name is present and it contains a prefix, then the SAX-writer attempts to resolve the prefix to a namespace.

If the SAX-attributes-handle is supplied, then attributes are written out after the name of the element, in the order that they are indexed in the SAX-attributes object. If they contain namespace information, then that information is handled as if the attribute were added using the INSERT-ATTRIBUTE() method.

If the STRICT attribute is TRUE, the FRAGMENT attribute is FALSE, and the call would result in more than one document-level element (that is, root node), then the method fails. Also, if STRICT is TRUE, an external DTD has been declared, and the call would create the root node, then the name used for the DTD declaration must match the name of the root node or the method fails.

See also: END-ELEMENT() method

---

**STARTUP-PARAMETERS attribute**

Returns a character string containing a comma-separated list of all startup parameters you defined at startup for the current ABL session.
STARTUP-PARAMETERS attribute

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

This list includes startup parameters defined in the ABL default startup parameter file ($DLC/startup.pf) or the file specified by the $PROSTARTUP environment variable, as well as startup parameters you specify on the command line or within a parameter file (.pf). The value of this attribute does not change during run time.

The startup parameter values in this list reflect initial parameter value settings. The value of a startup parameter during an ABL session can be different from its initial value setting. Some startup parameters have an equivalent session attribute you can use in ABL code to override the parameter value during a session. If you override a parameter value using an equivalent session attribute, the new value is not reflected in the list of startup parameters returned in this attribute.

If you defined any startup parameters in the default parameter file (startup.pf), or another parameter file specified by the Parameter File (-pf) startup parameter, the list includes the -pf *filename* parameter and all parameters defined in that parameter file, followed by (end .pf). For example:

```
-pf dbconnect.pf,-db sports2000,-H pclsmith,-S 5000,(end .pf)
```

A parameter file appears in the list whether or not it contains startup parameters. If a parameter file does not contain startup parameters, it appears in the list in the following format:

```
-pf *filename*,(end .pf)
```

The default parameter file (startup.pf) always appears in the list. The AVM expands the filename of only the default parameter file. All other filenames appear in the list as specified.

Individual startup parameters, defined within a parameter file or on the command line, appear in the list in the following format:

```
-parameter-name parameter-value,
```

If the startup parameter has no value, the list contains the startup parameter followed by a comma. No space appears before or after a comma, and no comma appears at the end of the list.

If the list of startup parameters includes duplicates, the last occurrence takes precedence and all other instances are ignored (even though they appear in the list).

If the list of startup parameters includes the Password (-P) or Proxy Password (-proxyPassword) parameters, the AVM substitutes six asterisks in place of the password value.

If the list of startup parameters contains a hyphen with no parameter name, the hyphen is ignored.
You can use the ENTRY function to parse the list of startup parameters. If you use the ENTRY function with the default delimiter (comma), the function separates the parameter entries wherever a comma appears. If a comma appears in the list as part of a parameter value, the function might not parse the list correctly. A comma separating two startup parameters, as opposed to being part of a parameter value, is always followed by “-” or “(end .pf)”. Based on this convention, you can examine the character(s) after a comma to determine whether the comma is separating two startup parameters or is part of a parameter value.

If you started your ABL session with the Statistics (-y), Statistics with CTRL+C (-yc), or Segment Statistics (-yd) startup parameter, you can use the SHOW-STATS statement to see the value of the STARTUP-PARAMETERS attribute. This statement includes the value of this attribute in the output to the client.mon file.

Table 105 shows examples of original command lines and their equivalent STARTUP-PARAMETERS attribute values.

<table>
<thead>
<tr>
<th>Original command</th>
<th>Value of the STARTUP-PARAMETERS attribute</th>

</tbody>
</table>

**STATE-DETAIL attribute**

A description that provides detail about the current state of the Client-principal object.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** Client-principal object handle

The AVM sets the value of this attribute, along with the LOGIN-STATE attribute, whenever the state of a Client-principal object changes. You can also set the value of this attribute when calling the AUTHENTICATION-FAILED( ) method to place a Client-principal object in an authentication failed state by specifying a reason for the authentication failure.

**See also:** AUTHENTICATION-FAILED( ) method, LOGIN-STATE attribute

**STATUS-AREA attribute**

Indicates whether a window has a status area.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** WINDOW widget

If the STATUS-AREA attribute is TRUE, the window has a status area.

You can set this attribute only before the window is realized.
STATUS-AREA-FONT attribute
(Graphical interfaces only)

The font number of the font used in the status area of a window.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** WINDOW widget

The font number represents an entry in the font table maintained by the FONT-TABLE handle.

STOP attribute

Set to TRUE, if the asynchronous request was executing when the client issued the CANCEL REQUESTS( ) method.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** Asynchronous request object handle

If the COMPLETE attribute is FALSE, the value of this attribute is the Unknown value (?). When the PROCEDURE-COMPLETE event is processed, this attribute is set to TRUE before the event procedure is executed if the remote request returned with an unhandled STOP condition; otherwise, it is set to FALSE.

STOP-PARSING( ) method

Causes the parser to stop parsing the XML document. This lets an application search for particular data, then abort the parse as soon as the data are found.

- **Return type:** LOGICAL
- **Applies to:** SAX-reader object handle

**Syntax**

```
STOP-PARSING ( )
```

STOP-PARSING( ) can stop a parse started by SAX-PARSE( ), SAX-PARSE-FIRST( ) or SAX-PARSE-NEXT( ). That is, the parse can be single call or multiple scan.

STOP-PARSING sets the PARSE-STATUS attribute to SAX-COMPLETE.

Within a callback, to invoke STOP-PARSING( ), use the SELF system handle, as shown in the following fragment:

```
SELF:STOP-PARSING( ).
```
If STOP-PARSING( ) is invoked in a callback or in any procedure called directly or indirectly by a callback, the AVM continues to execute the callback as usual, but when the callback finishes, control returns to the next ABL statement after the most-recently-executed SAX-PARSE( ), SAX-PARSE-FIRST( ), or SAX-PARSE-NEXT( ).

**STOPPED attribute**

Indicates whether the last compilation stopped prior to completion.

- **Data type:** LOGICAL
- **Access:** Readable
- **Applies to:** COMPILER system handle

When set to TRUE, the STOPPED attribute indicates that the last ABL compilation stopped before completion.

**STREAM attribute**

A value that specifies the character set used for operating system file I/O — "ibm850" or "iso8859-1".

- **Data type:** CHARACTER
- **Access:** Readable
- **Applies to:** SESSION system handle

The Stream Character Set (-stream) parameter sets the value of this attribute.

This attribute is obsolete. See the CPSTREAM attribute.

**STRETCH-TO-FIT attribute**

Forces the image to expand or contract to fit within the image widget’s boundaries.

- **Data type:** LOGICAL
- **Access:** Readable/Writeable
- **Applies to:** IMAGE widget

This attribute has no effect if an icon is displayed on the image widget.

**STRICT attribute**

Determines if the SAX-writer object should ensure that the XML document is well formed XML.
STRING-VALUE( ) method

The default value, TRUE, directs the object to ensure that the output is well formed XML. If a method call results in invalid XML, then the method fails, WRITE-STATUS is changed to SAX-WRITE-ERROR, and the stream is closed.

FALSE directs the object to generate warning messages and proceed with the write. If any warning message is generated, then the XML document will not be valid.

You can read this attribute at all times, but you can only write to it when the object’s WRITE-STATUS is either SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. That is, it can only be changed when the writer is not writing, otherwise it fails and generates an error message.

STRING-VALUE( ) method

The string value (which the AVM computes at run time) of the contents of the buffer-field object.

The STRING-VALUE( ) method uses the format attribute to convert the buffer value to a string.

Data type: CHARACTER
Access: Readable
Applies to: Buffer-field object handle

Syntax

```
STRING-VALUE ( [ i ] )
```

An integer expression representing a subscript, for fields that have extents.

SUBTYPE attribute

The subtype of a widget.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: BROWSE widget (column), COMBO-BOX widget, FILL-IN widget, MENU-ITEM widget, Server object handle, X-document object handle, X-noderef object handle

This attribute is read-only for combo boxes, the server object handle, the X-document object handle, and the X-noderef object handle. You can set this attribute only before the widget is realized.
For menu items, the value of this attribute is either "NORMAL", "SKIP", or "RULE". "NORMAL" is the default—a menu item that can be chosen, a toggle-box item, or read-only text. (In this case the READ-ONLY and TOGGLE-BOX attributes determine the specific type of the menu item.) "SKIP" specifies a blank line in the menu. "RULE" specifies a visible horizontal line in the menu.

For combo boxes, the value of this attribute is either "SIMPLE", "DROP-DOWN", or "DROP-DOWN-LIST". The DROP-DOWN-LIST subtype is the default. The SIMPLE and DROP-DOWN subtypes apply only to character-field or character-variable combo-box widgets in graphical interfaces only, and only in Windows. If you set the subtype of a combo-box widget to "SIMPLE" or "DROP-DOWN" in a character interface, the AVM treats the combo-box widget as having the "DROP-DOWN-LIST" subtype.

For browses, this attribute applies only to combo-box browse columns.

For fill-ins, the value of this attribute is either "PROGRESS" or "NATIVE". "PROGRESS" is the default. If set to "PROGRESS", the fill-in widget has the behavior of a standard ABL field in character mode. Otherwise, the field has the behavior of a fill-in that is native to the current graphical environment. The NATIVE option of the VIEW-AS phrase specifies that the field adhere to the native behavior of the current window system or environment.

For the X-document object handle or X-noderef object handle, this attribute returns the name of the object type (character representation of the DOM NodeType), which will be one of the following: ATTRIBUTE, CDATA-SECTION, COMMENT, DOCUMENT, DOCUMENT-FRAGMENT, ELEMENT, ENTITY-REFERENCE, PROCESSING-INSTRUCTION, or TEXT.

For the server object handle, this attribute identifies the type of server to which the server object is bound. This is either an AppServer or a Web service. This attribute is set during the execution of the CONNECT( ) method and can be one of three values. Before you invoke the CONNECT( ) method, the attribute value is set to the empty string (""). Once you invoke the CONNECT( ) method, the attribute value is set to either "APPSERVER" for an AppServer or "WEBSERVICE" for a Web service.

**SUPER-PROCEDURES attribute**

A list of the super procedure handles associated with a procedure file or with the current ABL session. The handles appear in last in first out (LIFO) order, comma-delimited, in character format. Returns the empty string for a Web service procedure.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** Procedure object handle, SESSION system handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

If there are no super procedures associated with a procedure file or with the current ABL session, the value of the SUPER-PROCEDURES attribute is the empty string.
SUPPRESS-NAMESPACE-PROCESSING attribute

Indicates whether namespace processing is suppressed.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** SAX-reader object handle, X-document object handle

FALSE, the default, indicates that namespace processing is not suppressed. TRUE indicates that namespace processing is suppressed.

For more information on accessing XML documents using the Document Object Model (DOM) and Simple API for XML (SAX) interfaces, see *OpenEdge Development: Working with XML*.

SUPPRESS-WARNINGS attribute

Indicates whether the AVM suppresses warning messages during the session.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

If TRUE, the AVM does not display warning messages during the session.

SYMMETRIC-ENCRYPTION-ALGORITHM attribute

A character string that specifies the name of the default cryptographic algorithm to use with the ENCRYPT and DECRYPT functions. The default value is “AES_CBC_128”.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** SECURITY-POLICY system handle

This string is a concatenation of three character expressions that identify an algorithm, mode, and key size. For a list the supported cryptographic algorithms, see the SYMMETRIC-SUPPORT attribute reference entry.

You are responsible for generating, storing, and transporting this value.

SYMMETRIC-ENCRYPTION-IV attribute

The default initialization vector value to use with the encryption key in the ENCRYPT and DECRYPT functions. The default value is the Unknown value (?), which indicates that no initialization vector value is used.
SYMmetric-encryption-key attribute

Data type: RAW
Access: Readable/Writeable
Applies to: SECURITY-POLICY system handle

Using an initialization vector value increases the strength of the specified encryption key (that is, it makes the key more unpredictable).

You are responsible for generating, storing, and transporting this value.

SYMmetric-encryption-key attribute

The default encryption key (a binary value) to use with the ENCRYPT and DECRYPT functions. The default value is the Unknown value (?)

Data type: RAW
Access: Writeable
Applies to: SECURITY-POLICY system handle

You may specify this key as a MEMPTR, CHARACTER, or LONGCHAR value, but the AVM treats it as a RAW.

If the value of this attribute is the Unknown value (?), you must provide the encryption key as an argument to the ENCRYPT and DECRYPT functions.

The AVM compares the size of the specified encryption key to the key size specified by the cryptographic algorithm. If the key sizes are inconsistent, the AVM generates a run-time error.

The AVM obscures this attribute value to protect it against unauthorized access. You are responsible for generating, storing, and transporting this value.

You can generate an encryption key, based on the PKCS#5/RFC 2898 standard, by using either the GENERATE-PBE-KEY function or the GENERATE-RANDOM-KEY function.

Note: Do not use the GENERATE-RANDOM-KEY function to assign a key value to this attribute directly. Doing so will render the key irretrievable (as this attribute is write-only).

SYMmetric-support attribute

Returns a comma-separated list of supported cryptographic algorithm names to use in encrypting and decrypting data. Each algorithm name is a concatenation of three character expressions that identify an algorithm, mode, and key size.

Data type: CHARACTER
Access: Readable
Applies to: SECURITY-POLICY system handle

Table 106 lists the supported cryptographic algorithm names.
**SYNCHRONIZE( ) method**

Synchronizes a hierarchy of data-relation queries on a parent buffer.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle

**Syntax**

```hBuff: SYNCHRONIZE ( )```

This method traverses the ProDataSet object hierarchy starting at buffer `hBuff` and reopens each data-relation query for the current parent at each lower level. Use this method to populate one or more related child buffers for the ProDataSet object buffer.

By default, if the query is associated with a browse, the synchronize action automatically refreshes the browse. If the query is not associated with a browse, the synchronize action automatically gets the first buffer in the query by invoking a GET FIRST operation. If there is a REPOSITION data relation and no browse, the synchronize action gets the next record in the query by invoking a GET NEXT operation.

**SYSTEM-ALERT-BOXES attribute**

Indicates whether the AVM displays system messages in alert boxes.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** SESSION system handle

If TRUE, the AVM displays system messages in alert boxes rather than in the message area.
SYSTEM-ID attribute

Returns the system ID of the external DTD from which an XML document was generated. This contains the path to the DTD which is either a file system path or an HTTP URL. The ABL parser uses this information to retrieve the DTD when parsing the document.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** X-document object handle

TAB-POSITION attribute

The tab order of a widget within its field group.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

You can change the tab order of the widget at the field level using the MOVE-BEFORE-TAB-ITEM( ) or MOVE-AFTER-TAB-ITEM( ) methods, and at the field group level using the FIRST-TAB-ITEM attribute or LAST-TAB-ITEM attribute.

TAB-STOP attribute

Returns TRUE if the widget is in its parent’s tab chain.

**Data type:** LOGICAL

**Access:** Readable/Writable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

Setting the TAB-STOP attribute to FALSE removes the widget from its parent’s tab chain. Setting the TAB-STOP attribute to TRUE adds the widget to the end of its parent’s tab chain. If the widget is already in the tab chain, its position does not change.

In Windows, the mnemonic key (ALT accelerator) for a widget will not work if the widget is removed from the tab order. Also, because the widget is not in the tab order, pressing TAB will not change focus from the widget.
TABLE attribute

The name of the database table containing the field associated with a widget, buffer, or buffer-field.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** BROWSE widget (browse and column), Buffer object handle, Buffer-field object handle, COMBO-BOX widget, EDITOR widget, FILL-IN widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

**Note:** The TABLE attribute of a buffer contains the name of the table, not the name of the buffer.

TABLE-CRC-LIST attribute

Returns a comma-separated list of the CRC value for each table referenced in the r-code file specified by the RCODE-INFO:FILE-NAME attribute.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** RCODE-INFO system handle

This list corresponds directly to the list generated by the TABLE-LIST attribute.

Use this attribute with the TABLE-LIST attribute to compare the CRC value for all tables referenced in the r-code file with those stored in the database to determine whether or not a procedure file needs to be recompiled after a database change.

If the r-code file was compiled without table references, this attribute returns the empty string (""").

TABLE-HANDLE attribute

Returns the handle of a temp-table object, if any, associated with the buffer object. If the buffer is not associated with a temp-table object, it returns the Unknown value (?).

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Buffer object handle

This attribute allows you to delete a default buffer object for a temp-table object by deleting the temp-table object (since it is illegal to delete the default buffer object itself).
TABLE-LIST attribute

Returns a comma-separated list of all tables referenced in the r-code file specified by the RCODE-INFO:FILE-NAME attribute. Each table reference includes the table name and related database name (for example: SPORTS.CUSTOMER).

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** RCODE-INFO system handle

This list corresponds directly to the list generated by the TABLE-CRC-LIST attribute.

Use this attribute with the TABLE-CRC-LIST attribute to compare the CRC value for all tables referenced in the r-code file with those stored in the database to determine whether or not a procedure file needs to be recompiled after a database change.

If the r-code file was compiled without table references, this attribute returns the empty string (""").

TABLE-NUMBER attribute

The sequence number, within the database, of the table that corresponds to a buffer.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer object handle

Tag property (ActiveX control)  
(Windows only; Graphical interfaces only)

A variable that lets the developer store an arbitrary string value.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Any ActiveX control

The Tag property is an extended ActiveX control property that lets the developer store an arbitrary string value and retrieve it later. The AVM does not use this property internally; rather, the property lets the developer store application-specific information with the control.

This property is initialized to an empty string.

**Note:** The length of the string cannot exceed 2,147,483,647 characters.
**TEMP-DIRECTORY attribute**

The name of the directory in which the AVM stores temporary files during the session.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

By default, this is the current working directory. Otherwise, it is the directory specified using the Temporary Directory (-T) parameter.

---

**TEMP-TABLE-PREPARE( ) method**

Signifies that all the field and index definitions for a temp-table have been supplied.

**Return type:** LOGICAL  
**Applies to:** Temp-table object handle

**Syntax**

```
TEMP-TABLE-PREPARE( temp-table-name-exp )
```

**temp-table-name-exp**  
A character expression that evaluates to a temp-table name to be used in subsequent query statements that refer to this temp-table.

The temp-table is in an UNPREPARED state after the first definitional method is called until this method is called. During this time, only ADD/CREATE type methods may be called.

The TEMP-TABLE-PREPARE( ) method must be called after all fields and indexes have been created and before any non-ADD/CREATE method can be called. This method causes the pending list of field and index definitions to become part of the actual temp-table object, which puts the temp-table in a PREPARED state (that is, makes it ready for use).

**Note:** The NAME attribute of the Temp-table object handle is writeable for dynamic and AVM-generated temp-tables. A new temp-table name cannot be assigned until the TEMP-TABLE-PREPARE() method has been executed.

---

**TEXT-SELECTED attribute**

Indicates whether text is currently selected in a widget.
THREE-D attribute

Data type: LOGICAL
Access: Readable
Applies to: BROWSE widget (column), COMBO-BOX widget, EDITOR widget, FILL-IN widget

The TEXT-SELECTED attribute is TRUE if text in the widget is currently selected.

THREE-D attribute
(Windows only; Graphical interfaces only)

Indicates whether the AVM displays widgets using a three-dimensional format.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: DIALOG-BOX widget, FRAME widget, SESSION system handle, WINDOW widget

If TRUE, the specified widgets are displayed in a three-dimensional format. For a frame or dialog box, any field-level widgets in the frame or dialog box are also displayed in three-dimensional format. If a frame has the THREE-D attribute set to TRUE, the default background color is the color Button Face rather than the color Window. For a window, setting this attribute changes the window background color to color Button Face only, and has no effect on any widgets contained in the window. Frames do not inherit the THREE-D attribute from a window or ancestor frame.

If the THREE-D attribute is TRUE for the SESSION handle, then all system dialog boxes and alert boxes are displayed in three-dimensional format.

You can set this attribute only before the widget is realized.

Note: To maintain size compatibility, the AVM sets the default vertical size of two-dimensional fill-ins equal to the vertical size of three-dimensional fill-ins. Also, ABL does not fully support the overlay of three-dimensional widgets. For more information, see the section on three-dimensional layout in OpenEdge Development: Programming Interfaces.

TIC-MARKS attribute
(Windows only; Graphical interfaces only)

Enables the display of short hash marks on the outside of a slider to help indicate the movement of the trackbar with the slider widget. The default is not to display tic marks. If you specify the TIC-MARKS option, it is assumed that you are using new code to create a slider, and the trackbar on the slider widget will be relatively large.

However, if you omit the TIC-MARKS option, the AVM assumes that you are migrating old code, and the default size of the slider is the size originally defined for the slider in the old code.
TIME-SOURCE attribute

Specifies the client or database server machine that serves as the time source for applications running during the ABL session.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: SESSION system handle

TIME-SOURCE accepts either of the following settings:

- "local" or the null string (""") — Your application uses the client machine as its time source. The default value is "local".
- "dbname" — Your application uses the machine running the server for the database with the name dbname as its time source.

All time-related language elements, such as the MTIME, NOW, TIME, TIMEZONE, and TODAY functions, use the specified time source. This attribute is useful for client/server applications that span time zones.

Table 107: TIC-MARK values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TOP</td>
<td>TIC-MARKS appear on the top of the slider only</td>
</tr>
<tr>
<td>BOTTOM</td>
<td>TIC-MARKS appear on the bottom of the slider only</td>
</tr>
<tr>
<td>LEFT</td>
<td>TIC-MARKS appear on the left side of the slider only</td>
</tr>
<tr>
<td>RIGHT</td>
<td>TIC-MARKS appear on the right side of the slider only</td>
</tr>
<tr>
<td>BOTH</td>
<td>TIC-MARKS appear on both sides of the slider</td>
</tr>
</tbody>
</table>

The TIC-MARKS attribute must be set before the slider is realized. Also, you can use the FREQUENCY attribute with the TIC-MARKS attribute to indicate how frequently a tic mark will display along the trackbar of a slider.
TIMEZONE attribute

Specifies the time zone offset from UTC, in minutes, to use for the current session.

Data type: INTEGER
Access: Readable/Writeable
Applies to: SESSION system handle

ABL uses the value to resolve the TODAY, TIME, NOW, MTIME, and TIMEZONE functions. ABL also uses the value to resolve the special TODAY and NOW initial values for database and temp-table fields with DATE, DATETIME, and DATETIME-TZ data types.

If the TIME-SOURCE attribute is set, then the TIMEZONE setting is ignored to a value other than "local" or the null string ("").

See also: TIME-SOURCE attribute

TITLE attribute

The title string a widget displays.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: BROWSE widget, DIALOG-BOX widget, FRAME widget, MENU widget (pop-up only), WINDOW widget

For browse widgets, pop-up menus, and frames, this attribute is writeable only before the widget is realized. However, you can modify an existing frame title after realization.

TITLE-BGCOLOR attribute
(Graphical interfaces only)

The color number for the background color of the widget title.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget, DIALOG-BOX widget, FRAME widget, MENU widget (pop-up only)

The color number represents an entry in the color table maintained by the COLOR-TABLE handle. This attribute is read-only for all applicable widget types. It is writeable only for backward compatibility and has no effect when you set it.
**TITLE-DCOLOR attribute**

*(Character interfaces only)*

The color number for the character-mode display color of the widget title.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, DIALOG-BOX widget, FRAME widget, MENU widget (pop-up only)

The color number represents an entry in the color table maintained by the COLOR-TABLE handle. This attribute is read-only for browse widgets.

---

**TITLE-FGCOLOR attribute**

*(Graphical interfaces only)*

The color number for the foreground color of the widget title.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, DIALOG-BOX widget, FRAME widget, MENU widget (pop-up only)

The color number represents an entry in the color table maintained by the COLOR-TABLE handle. This attribute is read-only for all applicable widget types. It is writeable only for backward compatibility and has no effect when you set it.

---

**TITLE-FONT attribute**

The font number for the font of the widget title.

**Data type:** INTEGER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, DIALOG-BOX widget, FRAME widget, MENU widget (pop-up only)

The font number represents an entry in the font table maintained by the FONT-TABLE handle. This attribute is read-only for all applicable widget types. It is writeable only for backward compatibility and has no effect when you set it.

---

**TOGGLE-BOX attribute**

Indicates whether a menu-item appears and acts like a toggle box.
TOOLTIP attribute

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** MENU-ITEM widget

If the TOGGLE-BOX attribute is TRUE, the menu item appears and interacts like a toggle box. You can set this attribute only before the widget is realized.

---

**TOOLTIP attribute**

(Windows only; Graphical interfaces only)

A help text message for a text field or text variable. The AVM automatically displays this text when the user pauses the mouse pointer over a widget for which a tooltip is defined.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, EDITOR widget, FILL-IN widget, IMAGE widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, and TOGGLE-BOX widget

You can add or change the TOOLTIP attribute at any time. If TOOLTIP is set to "" or the Unknown value (?), then the ToolTip is removed. No ToolTip is the default.

---

**TOOLTIPS attribute**

(Windows only; Graphical interfaces only)

Indicates whether ToolTip information is displayed when the mouse pointer pauses over a control for which tooltip information is defined.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** SESSION system handle

If TRUE, the ToolTip information that is defined for any controls associated with a given session displays when the mouse pointer pauses over a control. Otherwise, ToolTip information does not display for any controls in the session.

---

**Top property**

(Windows only; Graphical interfaces only)

The vertical position of the control-frame and control-frame COM object from the top border of the parent container widget, in pixels.
TOP-NAV-QUERY attribute

Let you get or set the default navigation query for a top-level buffer in a ProDataSet object.

Note: A top-level buffer is a ProDataSet object buffer that is not a child in any active data relation. There may be one or more top-level buffers in a ProDataSet object.

Data type: HANDLE
Access: Readable/Writeable
Applies to: ProDataSet object handle

Syntax

\[
\text{TOP-NAV-QUERY( index \mid buffer-name ) \[= \text{query object handle}\]}
\]

\(index\)

An integer expression that evaluates to the 1-based index of the top-level buffer.

\(buffer-name\)

A character expression that evaluates to the name of the top-level buffer.

\(\text{query object handle}\)

A handle to a query object.

See also: Query object handle

TOP-ONLY attribute

Indicates whether another frame or window can overlay a given frame or window, respectively.
If the TOP-ONLY attribute is TRUE for the frame, no other frame can overlay it.

If more than one window is designated as TOP-ONLY, they will all stay on top of all non-TOP-ONLY windows, but each can be brought to the foreground. That is, a TOP-ONLY window is always on top of all non-TOP-ONLY windows, but is not necessarily on top of all TOP-ONLY windows.

The TOP-ONLY behavior will be temporarily suspended while a dialog box is displayed to prevent the TOP-ONLY windows from covering the dialog-box.

A window cannot have both the TOP-ONLY and ALWAYS-ON-TOP attributes set to TRUE. Setting the TOP-ONLY attribute to TRUE will set the ALWAYS-ON-TOP attribute to FALSE. The default value of the TOP-ONLY attribute is FALSE.

When using .NET forms with ABL windows in an ABL session, setting this attribute to TRUE on an ABL window enables the specified window to overlay all other .NET forms and non-TOP-ONLY windows in the session. However, .NET forms do not have a corresponding property or method to specify similar behavior for a form. Thus, you cannot have a .NET form in an ABL session that overlays all other forms and windows in the session.

See also: ALWAYS-ON-TOP attribute

**TRACKING-CHANGES attribute**

Set to TRUE to start tracking changes to the data in an individual ProDataSet temp-table. The AVM tracks changes to the temp-table until you set this attribute to FALSE. When this attribute is FALSE, any changes you make to the data in the temp-table are considered part of the fill process. The default value is FALSE.

For all other temp-tables that are not part of a ProDataSet, this attribute has the Unknown value (?).

Data type: LOGICAL  
Access: Readable/Writeable  
Applies to: Temp-table object handle  

When the TRACKING-CHANGES attribute is set to TRUE for a ProDataSet temp-table, the AVM tracks changes to the data in that temp-table using a before-image table that contains the original version of each row. You can think of the temp-table itself as the after-image because it contains the latest version of each row.

Note: If you SHARE a static ProDataSet, you must also SHARE all of its temp-tables. A SHARED static temp-table cannot have a before-image table. Therefore, you cannot track changes to its temp-tables.
Every row in the after-image table that has been modified or created corresponds to a row in the before-image table. Deleted rows do not appear in the after-image table, because it reflects the current state of the data. Every row in the before-image table has a non-zero ROW-STATE attribute value, because every row in the before-image table is the before-image of a deleted, created, or modified row in the after-image table. Unchanged rows do not appear in the before-image table.

You can track newly created rows and changed rows through either the before-image table or the after-image of the table. However, since deleted rows do not appear in the after-image table, it is better to track changes through the before-image table.

You might want to set TRACKING-CHANGES back to FALSE for a temp-table when you are ready to:

- Accept the changes using the ACCEPT-CHANGES( ) method or the ACCEPT-ROW-CHANGES( ) method
- Reject the changes using the REJECT-CHANGES( ) method or the REJECT-ROW-CHANGES( ) method
- Get and merge the changes using the GET-CHANGES( ) method and the MERGE-CHANGES( ) method or MERGE-ROW-CHANGES( ) method, respectively

**TRANSACTION attribute**

A handle to the current transaction object. Returns the Unknown value (?) for a Web service procedure.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** Procedure object handle, SOURCE-PROCEDURE system handle, TARGET-PROCEDURE system handle, THIS-PROCEDURE system handle

The transaction handle returned by this attribute provides attributes and methods that allow you to manage a transaction object running on an AppServer. In an ABL client session, or in an AppServer session that has no active transaction initiating procedure, you can only use the IS-OPEN attribute to check whether a transaction is open.

For more information on the AppServer and transaction initiating procedures, see the TRANSACTION-MODE AUTOMATIC statement reference entry and *OpenEdge Application Server: Developing AppServer Applications*. For more information on the attributes and methods provided by the transaction handle, see the Transaction object handle reference entry in the “Handle Reference” section on page 1189.

**TRANSPARENT attribute**

Makes the background color of the image transparent. The background color is determined by the color of the pixel in the lower-left corner of the image.
**TRANS-INIT-PROCEDURE attribute**

Data type: LOGICAL
Access: Readable/Writeable
Applies to: IMAGE widget

The TRANS-INIT-PROCEDURE attribute overrides the CONVERT-3D-COLORS attribute; if both TRANS-INIT-PROCEDURE and CONVERT-3D-COLORS are set to TRUE, CONVERT-3D-COLORS is ignored.

This attribute has no effect if an icon is displayed on the image widget.

---

**TRANS-INIT-PROCEDURE attribute (AppServer only)**

The handle to the transaction initiating procedure that started the currently-open automatic transaction.

Data type: HANDLE
Access: Readable
Applies to: Transaction object handle

You can use this procedure handle to access the attributes and methods of the active transaction initiating procedure or to delete the procedure, thus terminating the automatic transaction.

If no automatic transaction is active, TRANS-INIT-PROCEDURE returns an invalid handle. To check a handle for validity, use the VALID-HANDLE function.

For information on automatic transaction initiating procedures, see the TRANSACTION-MODE AUTOMATIC statement reference entry. For more information on the AppServer, see *OpenEdge Application Server: Developing AppServer Applications*.

---

**TYPE attribute**

The type of a handle.

Data type: CHARACTER
Access: Readable
Applies to: Asynchronous request object handle, AUDIT-CONTROL system handle, AUDIT-POLICY system handle, BROWSE widget (browse, column, and cell), Buffer object handle, Buffer-field object handle, BUTTON widget, Call object handle, Client-principal object handle, CLIPBOARD system handle, CODEBASE-LOCATOR system handle, COLOR-TABLE system handle, COMBO-BOX widget, COMPILER system handle, CONTROL-FRAME widget, CURRENT-WINDOW system handle, Data-relation object handle, Data-source object handle, DEBUGGER system handle, DEFAULT-WINDOW system handle, DIALOG-BOX widget, DSLOG-MANAGER system handle, EDITOR widget, ERROR-STATUS system handle, FILL-IN widget, FOCUS system handle, FONT-TABLE system handle, FRAME
The TYPE attribute returns the widget or handle type. Some examples are "WINDOW", "FRAME", "BUTTON", "MENU", "SAX-ATTRIBUTES", "SAX-READER", and "SERVER".

For AppServer and Web service handles, the TYPE attribute returns "SERVER".

If a system handle (such as CURRENT-WINDOW or FOCUS) refers to a user interface widget, the TYPE attribute returns the type of that widget. If a system handle (such as SESSION or CLIPBOARD) refers to an ABL status or system object, the TYPE attribute value is "PSEUDO-WIDGET".

For procedure handles and system handles that refer to procedures (such as THIS-PROCEDURE), the TYPE attribute returns "PROCEDURE".

For an asynchronous request handle, the TYPE attribute returns "ASYNC-REQUEST".

For the ProDataSet, Data-relation, and Data-source object handles, this attribute returns "DATASET", "DATA-RELATION", and "DATA-SOURCE", respectively.

For a server-socket handle, the TYPE attribute returns "SERVER-SOCKET", and for a socket handle, it returns "SOCKET".

For the SOAP-fault and SOAP-fault-detail object handles, this attribute returns "SOAP-FAULT" and "SOAP-FAULT-DETAIL", respectively.

For the SOAP-header and SOAP-header-entryref object handles, this attribute returns "SOAP-HEADER" and "SOAP-HEADER-ENTRYREF", respectively.

For the X-document and X-noderef object handles, the TYPE attribute returns "X-DOCUMENT" and "X-NODEREF", respectively.

For browse columns, the TYPE attribute returns "COMBO-BOX", "FILL-IN", or "TOGGLE-BOX". If you specify the Browse Column Type (-browcoltype) startup parameter, the TYPE attribute for browse columns returns "BROWSE-COLUMN" regardless of the actual column type.
UNDO attribute

If TRUE, the temp-table is UNDO; if FALSE, the temp-table is NO-UNDO. The default is FALSE (NO-UNDO). The attribute can be set if there is no active transaction. Within an active transaction, it can be set as long as the temp-table is empty.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** Temp-table object handle

UNIQUE-ID attribute

A value, with one noted exception, that is guaranteed unique for a given handle object type within an ABL session.

**Data type:** INTEGER  
**Access:** Readable  
**Applies to:** Buffer object handle, Buffer-field object handle, Procedure object handle, ProDataSet object handle, Query object handle, SAX-attributes object handle, SAX-reader object handle, SOAP-header object handle, SOAP-header-entryref object handle, SOURCE-PROCEDURE system handle, Target-PROCEDURE system handle, Temp-table object handle, THIS-PROCEDURE system handle, X-document object handle, X-noderef object handle

So, for example, the value of this attribute for a temp-table handle and a ProDataSet handle can be the same. However, the handles for no two temp-tables share this value.

The exception is the X-noderef object handle. The UNIQUE-ID attribute for an x-noderef handle is only unique within a given XML document.

**Note:** The value of the HANDLE attribute is guaranteed to be unique among the HANDLE attributes for all object instances in an ABL session.

UNIQUE-MATCH attribute  
*(Windows only; Graphical interfaces only)*

Specifies that the combo-box widget automatically complete keyboard input based on a unique match to items in the drop-down list.
UPDATE-ATTRIBUTE( ) method

When the UNIQUE-MATCH attribute is TRUE, the widget’s edit control compares the input to the items in the drop-down list. After each incremental character keystroke, the edit control searches through the items in the drop-down list for a unique match. When a unique match is found, the full item is displayed in the edit control. The automatically completed portion of the item is highlighted. You can replace the highlighted portion of the item by typing over it, or you can delete the highlighted portion of the item using the DELETE key or the BACKSPACE key. The default value is FALSE.

For browsers, this attribute applies only to combo-box browse columns.

**UPDATE-ATTRIBUTE( ) method**

Finds an attribute and updates its value within a SAX-attributes object.

**Return type:** LOGICAL

**Applies to:** SAX-attributes object handle

**Syntax**

```
UPDATE-ATTRIBUTE( { attribute-name | index }, attribute-value  
[ , namespaceURI ] )
```

**attribute-name**

A CHARACTER expression evaluating to the fully qualified or unqualified name of the attribute.

**index**

An integer expression evaluating to the position of the attribute in the attribute list. The first attribute has an index of 1. When using index, namespaceURI must be the Unknown value (?), an empty string, or not supplied. Otherwise, an invalid argument error will be raised.

**attribute-value**

A CHARACTER expression evaluating to the value of the attribute.

**namespaceURI**

A CHARACTER expression evaluating to:

- The URI of the attribute
- A zero-length string
- The Unknown value (?) if the attribute doesn’t contain a namespace
Call this method to update an attribute value within a SAX-attributes object. For example, if an XML element obtained from the SAX-reader object need to be modified before being used to write the XML element to a document being written by the SAX-writer object, use this method to find and update the attributes.

The index values of attributes left in the list is then updated to reflect the removed attribute. The NUM-ITEMS value will also be decremented to reflect the removed attribute.

If the method fails to find a match, because the name is not found or the index position is invalid, then the method will return FALSE.

If using an attribute-name, the method updates the first match it finds in the list.

The following are examples:

```
DEFINE VARIABLE hSAX-attributes as HANDLE.
CREATE SAX-ATTRIBUTES hSAX-attributes.

hSAX-attributes:INSERT-ATTRIBUTE( "language", "EN" ). /* index = 1 */
hSAX-attributes:INSERT-ATTRIBUTE( "year", "2005" ). /* index = 2 */

hSAX-attributes:UPDATE-ATTRIBUTE( "year", "2006" ).
hSAX-attributes:UPDATE-ATTRIBUTE( 2, "2007" ).
```

See also: INSERT-ATTRIBUTE( ) method, REMOVE-ATTRIBUTE( ) method

---

**URL attribute**

A URL to connect to an AppServer, through the AppServer Internet Adapter (AIA), or a web server.

**Data type:** CHARACTER

**Access:** Readable

**Applies to:** CODEBASE-LOCATOR system handle

Valid URL protocols depend on the LOCATOR-TYPE. If LOCATOR-TYPE is "AppServer", valid URL protocols include: HTTP, HTTPS, and AppServer. If LOCATOR-TYPE is "InternetServer", valid URL protocols include: HTTP, HTTPS, and FILE.

---

**URL-DECODE( ) method**

Returns a URL string to decode. This method is called by the url-decode WebSpeed API function. Intended for internal use only.
URL-ENCODE() method

Returns characters to encode. This method is called by the url-encode WebSpeed API function. Intended for internal use only.

Return type: CHARACTER
Applies to: WEB-CONTEXT system handle

URL-PASSWORD attribute

Password parameter for connecting to the server referenced in the URL, if required by the URL protocol.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: CODEBASE-LOCATOR system handle

URL-USERID attribute

Userid parameter for connecting to the server referenced in the URL, if required by the URL protocol.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: CODEBASE-LOCATOR system handle

USER-ID attribute

The user ID associated with a Client-principal object. You must set this attribute before you can seal the associated Client-principal object using the SEAL() method.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: Client-principal object handle

If you specify the Unknown value (?) or the empty string (""), the AVM generates a run-time error.

Once the Client-principal object is sealed, this attribute is read-only.
V6DISPLAY attribute
(Windows only)

Indicates whether the AVM follows Progress Version 6 rules or Progress Version 7 rules when it lays out and displays widgets in Windows. This attribute lets you compile and execute Progress Version 6 applications on Progress Version 7 in Windows.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: SESSION system handle

If the V6DISPLAY attribute is TRUE, the AVM uses Version 6 rules to manage the display. That is:

- The default font is the default system fixed pitch font (overridable using the DefaultFixedFont parameter in the current environment, which might be the Registry (Windows only) or an initialization file).
- All fill-ins have no borders.
- Fill-ins enabled for input use an underline version of the system fixed pitch font (overridable using the DefaultUpdateFont parameter in the current environment, which might be the Registry (Windows only) or an initialization file).
- The default window size (row/column) is 25 by 80 (overridable in the current environment, which might be the Registry (Windows only) or an initialization file).

Note: PUT SCREEN output is not restorable in graphical environments.

To run an application with V6DISPLAY set to TRUE, you must compile the application with the V6DISPLAY set to TRUE.

Notes: The OpenEdge ADE toolset was not compiled or designed to run in V6DISPLAY mode. Running the OpenEdge ADE in V6DISPLAY mode may result in clipped display elements and other unexpected behavior.

Setting V6DISPLAY to TRUE when running the OpenEdge ADE toolset may also degrade application compilation performance.

This attribute provides the same functionality as the V6Display parameter in the current environment, which might be the Registry (Windows only) or an initialization file. For more information on environments, see the chapter on user interface environments in OpenEdge Deployment: Managing ABL Applications.

VALIDATE( ) method

Executes any validation tests established in a database or specified by the VALIDATE option of the Format phrase.
Return type: LOGICAL
Applies to: BROWSE widget (browse and column), COMBO-BOX widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, RADIO-SET widget, SELECTION-LIST widget, SLIDER widget, TOGGLE-BOX widget

Syntax

```
VALIDATE ( [ "ENABLED-FIELDS" ] )
```

"ENABLED-FIELDS"

Validate enabled fields only.

If this option does not appear, the VALIDATE method validates all fields, whether enabled or not.

For a supported field-level widget, this method executes the validation test associated with the underlying field or variable.

For a frame or dialog box, this method executes the validation tests for every supported field-level widget in the frame or dialog box (except the browse, which you must VALIDATE explicitly). If the test for any field-level widget in the frame fails, the AVM displays the validation message and gives focus to the first widget in the frame or dialog box that is both visible and sensitive and whose data has failed validation.

For a browse, VALIDATE executes all validation tests associated with the browse and its children.

**Note:** During data entry, any widget that receives input focus is always validated. This method allows your procedure to validate any and all widgets in a frame, whether or not they currently have input focus.

If the validation is successful, the method returns TRUE. Otherwise, it returns FALSE.

---

**VALIDATE-EXPRESSION attribute**

The value of the validation expression in the database schema for the database field that corresponds to the buffer-field.

The VALIDATE-EXPRESSION attribute lets you write user input validation code for interfaces that the AVM’s automatic user input validation does not support.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Buffer-field object handle

If a buffer-field is associated with a dynamic browse column, you should set the buffer-field’s VALIDATE-EXPRESSION attribute before the dynamic browse column is added to the browser (via ADD-LIKE-COLUMN( )). The validation expression is compiled at this time. If the VALIDATE-EXPRESSION attribute is changed later, it is ignored.
VALIDATE-MESSAGE attribute

The value of the validation message in the database schema for the database field that corresponds to the buffer-field.

The VALIDATE-MESSAGE attribute lets you write user input validation code for interfaces that the AVM’s automatic user input validation does not support.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Buffer-field object handle

VALIDATE-SEAL( ) method

Validates the message authentication code (MAC) generated by the SEAL( ) method to seal a Client-principal object.

You can use this method to validate the seal whenever necessary.

**Return type:** LOGICAL  
**Applies to:** Client-principal object handle

**Syntax**

```
VALIDATE-SEAL( [validation-key ] )
```

**validation-key**

An optional character expression containing the authentication domain’s key to use in validating the MAC that sealed the Client-principal object. The AVM converts this key to UTF-8 before using it, which ensures a consistent value regardless of code page settings.

If you specify a validation key, the AVM uses that key to validate the seal. If you do not specify a validation key, the AVM uses the authentication domain’s key stored in the application’s trusted authentication domain registry for the Client-principal object to validate the seal. The AVM validates the seal by comparing it to the MAC generated by either the specified validation key or the authentication domain key stored in the trusted authentication domain registry. If the seal matches the MAC, then the seal is valid and this method returns TRUE. Otherwise, the seal is invalid and this method returns FALSE.

If the Client-principal object is not sealed and not in the LOGIN state, the AVM generates a run-time error.

The AVM also checks the LOGIN-EXPIRATION-TIMESTAMP attribute. If the Client-principal object expires before you can validate its seal, the AVM sets the LOGIN-STATE attribute to “EXPIRED” and returns FALSE.

Calling this method does not generate an audit event or an audit record.

The following code fragment illustrates how to use the VALIDATE-SEAL( ) method:
VALIDATE-XML attribute

Sets validation on parsing when an XML document is posted to the transaction server. The default is NO.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** WEB-CONTEXT system handle

VALIDATION-ENABLED attribute

Indicates whether the parser validates the XML document against the DTD.

**Data type:** LOGICAL  
**Access:** Readable/Writable  
**Applies to:** SAX-reader object handle

TRUE indicates that the parser validates the XML document against the DTD. The default is TRUE. Validation errors are caught in a callback event procedure named `error`. If this callback procedure is not implemented, then validation errors cannot be caught.

**Note:** If VALIDATION-ENABLED is FALSE, the parser still checks that the XML document is well formed.

VALUE attribute

The data values in the system clipboard.
VERSION attribute

Determines the value of the version string in the XML declaration of a SAX-writer object.

| Data type: | CHARACTER |
| Access: | Readable/Writeable |
| Applies to: | SAX-writer object handle |

You can set the attribute to the value of the version string in the XML declaration. The default value is "1.0". For example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
```

You can read this attribute at all times, but you can only write to it when the WRITE-STATUS is either SAX-WRITE-IDLE or SAX-WRITE-COMPLETE. That is, it can only be changed when the writer is not writing, otherwise it fails and generates an error message.

If STRICT is TRUE, the only valid version is "1.0", and the VERSION attribute cannot be changed or you get an error message. If STRICT is FALSE, the version in the prolog of the XML document will match the value of the VERSION attribute.

If the value is an empty string (""), then the version string will not appear in the XML declaration.
VIEW-AS attribute

Sets the widget type of a dynamic or static browse column for a buffer-field object.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Buffer-field object handle

Set this attribute to specify the widget type for a dynamic browse column (that is, a column created with the ADD-LIKE-COLUMN() method or ADD-COLUMNS-FROM() method). Valid values are “COMBO-BOX”, “DROP-DOWN”, “DROP-DOWN-LIST”, “FILL-IN” and “TOGGLE-BOX”. The default value is “FILL-IN”.

As an added convenience, you can also create a combo-box browse column by setting the buffer-field’s VIEW-AS attribute to “COMBO-BOX” and setting its SUBTYPE attribute to either “DROP-DOWN” or “DROP-DOWN-LIST”.

A widget type of “COMBO-BOX” or “DROP-DOWN-LIST” is valid only when the buffer-field’s data type is CHARACTER, DATE, DECIMAL, INTEGER, INT64 or LOGICAL. A widget type of “DROP-DOWN” is valid only when the buffer-field’s data type is CHARACTER. A widget type of “TOGGLE-BOX” is valid only when the buffer-field’s data type is LOGICAL. If the widget type is not valid for the buffer-field’s data type, the AVM generates a run-time error.

Setting this attribute to the Unknown value (?) restores the default value of “FILL-IN”.

You can query this attribute for the widget type of a dynamic or static browse column.

For any type of combo-box browse column, this attribute returns “COMBO-BOX”. Refer to the column’s SUBTYPE attribute to determine whether the combo-box is a DROP-DOWN or DROP-DOWN-LIST combo-box.

VIEW-FIRST-COLUMN-ON-REOPEN attribute

Controls whether the browse, when an OPEN Query statement is run, displays the first column in the viewport or the columns that were in the viewport before the Query was reopened.

**Data type:** LOGICAL  
**Access:** Readable/Writeable  
**Applies to:** BROWSE widget

When the VIEW-FIRST-COLUMN-ON-REOPEN attribute is set to:

- TRUE, and the query for a browse is reopened, the browse displays the first row of data and the first column in the leftmost position
- FALSE, and the query for a browse is reopened, the browse displays the first row of data and the columns that were displayed in the viewport before the query was reopened
For example, if this attribute is set to FALSE and a user had scrolled to the far-right column, the next time the browse for a query is reopened, the browse displays the first row of data and the far-right column.

The default value is FALSE.

**VIRTUAL-HEIGHT-CHARS attribute**

The maximum height of the widget, in character units.

**Data type:** DECIMAL  
**Access:** Readable/Writeable  
**Applies to:** DIALOG-BOX widget, FRAME widget, WINDOW widget

For a non-scrollable frame, VIRTUAL-HEIGHT-CHARS has the same value as the HEIGHT-CHARS attribute. For a scrollable frame, VIRTUAL-HEIGHT-CHARS specifies the height of the entire frame while HEIGHT-CHARS specifies the height of the visible portion of the frame.

**VIRTUAL-HEIGHT-PIXELS attribute**

The maximum height of the widget, in pixels.

**Data type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** DIALOG-BOX widget, FRAME widget, WINDOW widget

For a non-scrollable frame, VIRTUAL-HEIGHT-PIXELS has the same value as the HEIGHT-PIXELS attribute. For a scrollable frame, VIRTUAL-HEIGHT-PIXELS specifies the height of the entire frame while HEIGHT-PIXELS specifies the height of the visible portion of the frame.

**VIRTUAL-WIDTH-CHARS attribute**

The maximum width of the widget, in character units.

**Data type:** DECIMAL  
**Access:** Readable/Writeable  
**Applies to:** DIALOG-BOX widget, FRAME widget, WINDOW widget

For a non-scrollable frame, VIRTUAL-WIDTH-CHARS has the same value as the WIDTH-CHARS attribute. For a scrollable frame, VIRTUAL-WIDTH-CHARS specifies the width of the entire frame while WIDTH-CHARS specifies the width of the visible portion of the frame.
VIRTUAL-WIDTH-PIXELS attribute

The maximum width of the widget, in pixels.

Data type: INTEGER
Access: Readable/Writeable
Applies to: DIALOG-BOX widget, FRAME widget, WINDOW widget

For a non-scrollable frame, VIRTUAL-WIDTH-PIXELS has the same value as the WIDTH-PIXELS attribute. For a scrollable frame, VIRTUAL-WIDTH-PIXELS specifies the width of the entire frame while WIDTH-PIXELS specifies the width of the visible portion of the frame.

VISIBLE attribute

Indicates whether a widget is currently visible on the display.

Data type: LOGICAL
Access: Readable/Writeable
Applies to: BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DEBUGGER system handle, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU widget, MENU-ITEM widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

This attribute is read-only for field groups, menus, menu items, and submenus. A field-level widget must be specified in a frame definition before you set its VISIBLE attribute.

The behavior of the VISIBLE attribute depends on the setting of the HIDDEN attribute of related widgets:

- When you set the VISIBLE attribute of a window to TRUE:
  - The AVM displays that window and the widgets it contains whose VISIBLE attributes are already set to TRUE. Otherwise, you must explicitly DISPLAY or VIEW a widget, or otherwise set a widget’s VISIBLE attribute to TRUE in order to display it in the window.
  - The AVM displays that window and all ancestor windows only if no ancestor window has its HIDDEN attribute set to TRUE. If the AVM displays the window, it also displays all descendant windows down to, but not including, the first descendant window whose HIDDEN attribute is set to TRUE.

- When you set the VISIBLE attribute of any widget within a window to TRUE, the AVM displays that widget, any ancestor frames, and the window (if necessary), unless the HIDDEN attribute of the window is TRUE. If the window’s HIDDEN attribute is TRUE, the AVM sets the VISIBLE attributes of the widget and any ancestor frames to TRUE and sets the HIDDEN attributes of the widget and its ancestor frames to FALSE without displaying them.
When you set the VISIBLE attribute of a frame to TRUE, the AVM displays all of its field-level widgets and descendant frames, except those whose HIDDEN attributes are TRUE.

When you explicitly set the VISIBLE attribute of any widget to TRUE, the AVM sets its HIDDEN attribute to FALSE. If you explicitly set the VISIBLE attribute of a field-level widget or child frame to FALSE while its parent frame remains visible, the AVM also sets the HIDDEN attribute of the field-level widget or child frame to TRUE. If you explicitly set the VISIBLE attribute of a child window to FALSE, the HIDDEN attribute of the child window remains unchanged, whether or not the parent window is visible.

The following behavior is true for the browse column:

- The syntax of the VISIBLE attribute for the browse column is as follows:

  \[ \text{VISIBLE } [ \text{ IN BROWSE browse-name } ] \]

- The behavior of the VISIBLE attribute for a browse column does not depend on the setting of the HIDDEN attribute of the related widget.

- Changing the VISIBLE attribute of a browse column may affect which columns are locked if NUM-LOCKED-COLUMNS has been set. This is because NUM-LOCKED-COLUMNS only applies to visible columns. For example, if the first three columns of a browse are locked and the second column is made not VISIBLE, the fourth column will then become locked.

- If a widget is not already realized and you set its VISIBLE attribute to TRUE, the AVM realizes that widget.

- In character mode, the VISIBLE attribute is always set to TRUE.

---

**WARNING attribute**

Indicates whether the last compilation produced warning messages.

**Data type:** LOGICAL

**Access:** Readable

**Applies to:** COMPILER system handle

If the WARNING attribute is TRUE, there were warning messages from the last compilation.

---

**WC-ADMIN-APP attribute**

Indicates whether a WebClient application is an Administrator installation or a personal installation. If TRUE, a user with Administrator privileges installed the application. If FALSE, the user did not have those privileges and installed a personal instance of the application.
WHERE-STRING attribute

Returns and allows you to modify the current WHERE expression from the query generated for a specified data-relation that links the child table to its parent.

**Data type:** CHARACTER

**Access:** Readable/Writeable

**Applies to:** Data-relation object handle

This attribute evaluates to the WHERE expression from the query that the AVM generates for you based on the data-relation between parent and child buffers. You can also use this attribute to build an extended query of your own based on this default relationship.

**Note:** You can provide the initial WHERE expression for a query using the FILL-WHERE-STRING attribute.

If you assign a new value to the attribute, the AVM uses the new WHERE expression when it re-opens the query during navigation to filter the child table of the data-relation. When you set this attribute, if the AVM finds an error in the new WHERE expression, it raises a run-time error on the assignment.

The NAME attribute of the Temp-table object handle is writeable for dynamic and AVM-generated temp-tables. You might need to update a WHERE-STRING that references a renamed temp-table with new strings using the new table name.

Typically, you modify an existing WHERE expression by appending additional conditions to it, as shown in the `r-wherestr.p` example procedure. This example provides the initial WHERE expression using the FILL-WHERE-STRING attribute. It then generates the complete initial query for the data-relation with the call to the ProDataSet FILL( ) method, and uses the WHERE-STRING attribute to modify the existing WHERE expression to further filter the query buffers.
**Widget-Handle property**

(Windows only; Graphical interfaces only)

The handle of the control frame associated with the control-frame COM object.

**Return type:** HANDLE  
**Access:** Readable  
**Applies to:** CONTROL-FRAME widget, COM object

**Note:** References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

---

**See also:** FILL-WHERE-STRING attribute, QUERY attribute

---

**r-wherestr.p**

```plain

WAIT-FOR WINDOW-CLOSE OF CURRENT-WINDOW.
```

---
**WIDGET-ENTER attribute**

A handle, in a trigger associated with an ENTRY event or a LEAVE event, to the next widget to receive input focus.

- **Data type:** HANDLE
- **Access:** Readable
- **Applies to:** LAST-EVENT system handle

The WIDGET-ENTER attribute is meaningful only within an ENTRY or LEAVE trigger.

For browse widgets, WIDGET-ENTER is different depending on whether the browse is editable or read-only. For editable browse widgets, WIDGET-ENTER contains the handle of the column with focus. For read-only browse widgets, WIDGET-ENTER contains the handle of the browse.

**WIDGET-ID attribute**  
*(Windows only; Graphical interfaces only)*

An application-defined widget ID for a static or dynamic widget. The value of this attribute must be an even INTEGER value between 2 and 65534, inclusive, and it must be unique across all widget IDs in a window.

- **Data type:** INTEGER
- **Access:** Readable/Writeable
- **Applies to:** BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FILL-IN widget, FRAME widget, IMAGE widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget

Specify an application-defined widget ID when you want to identify the widget at run time while testing your ABL GUI application with a third-party automated test tool. When specified, the AVM uses this application-defined widget ID when creating the widget at run time, instead of using the widget ID it normally generates by default. The widget ID value of any given widget remains the same across ABL sessions, unless you purposely change the value of the widget ID using this attribute. This allows a third-party automated test tool to identify the same widget consistently each time you run the tool with your application.

To enable application-defined widget IDs in your ABL GUI application, you must specify the Use Widget ID (`-usewidgetid`) startup parameter. For more information about this startup parameter, see *OpenEdge Deployment: Startup Command and Parameter Reference*.

If you do not specify the Use Widget ID (`-usewidgetid`) startup parameter, and your application contains application-defined widget IDs, the AVM ignores any WIDGET-ID attribute or option settings and generates its own widget IDs. In this case, querying the WIDGET-ID attribute returns the Unknown value (?).
If you specify the Use Widget ID (--usewidgetid) startup parameter and your application contains application-defined widget IDs, or a combination of application-defined and ABL-defined widget IDs, the AVM honors any application-defined widget IDs and assigns ABL-defined widget IDs as necessary. In this case, querying the WIDGET-ID attribute returns the assigned widget ID (whether it be an application-defined value or an ABL-defined value).

For more information about using application-defined widget IDs when testing ABL GUI applications with third-party automated test tools, see OpenEdge Development: Programming Interfaces.

You can set this attribute only before the widget is realized. Once the widget is realized, this attribute is read-only.

For frames, the AVM uses this attribute value as the basis for assigning a unique widget ID for each child widget within the frame by combining the frame widget ID with the child widget ID. For example, a frame defined with a widget ID of 100 that contains a fill-in widget defined with a widget ID of 2 results in a fill-in widget with a widget ID of 102 at run time. In this way, the widget ID of each child widget within a given frame is unique within that frame, as well as across multiple instances of that frame within a given window. If the value of the frame widget ID combined with the child widget ID is greater than 65534, the AVM displays a warning message and assigns a unique widget ID to the child widget.

When a frame is displayed as a down frame, you can specify an application-defined widget ID for the first instance of the widget on the down frame. The AVM assigns a unique widget ID for each additional instance of the widget on the down frame (based on the number of iterations in the down frame) using consecutive even numbers. Likewise, when a frame contains extent fields, the AVM assigns a widget ID to each of the extent elements in the frame.

When a frame is displayed as a dialog box, which is a special type of frame displayed in its own window, the widget ID for any child widgets inside the dialog box must be unique only within that dialog box.

**Note:** The default widget ID for a frame is 0 (zero). Use caution when defining multiple frames, or multiple instances of a frame, in a single window and allowing the widget IDs to default to 0, because you are more likely to encounter a duplicate widget ID conflict.

For radio-set widgets, which are built with individual radio buttons, the AVM uses this attribute value as the basis for assigning a unique widget ID for each radio button of the given radio-set widget using consecutive even numbers.

For browse widgets, the AVM uses this attribute value as the basis for assigning a unique widget ID for each column within the browse by automatically incrementing the browse widget ID by 1 for each column within the browse sequentially from left to right.

ABL also provides for assigning widget IDs to widget labels by reserving the previous odd value of each widget ID for the widget’s label. For example, if you assign a widget a widget ID of 10, ABL reserves widget ID 9 for the widget’s label. ABL does not provide for assigning widget IDs to browse column labels.

You cannot specify an application-defined widget ID for FIELD-GROUP, LITERAL, MENU, MENU-ITEM, SUB-MENU, or WINDOW widgets.
If you specify an invalid widget ID value in a static widget definition, ABL generates a compiler error whether the Use Widget ID (-usewidgetid) startup parameter is specified or not. If you specify an invalid widget ID value in a dynamic widget definition, the AVM generates a run-time error only when the startup parameter is specified.

**Caution:** To avoid duplicate widget ID conflicts, within and across multiple instances of a widget in a single window, be sure to specify widget IDs within numeric ranges that take other widgets into account. For example, do not specify frame widget IDs in multiples of 10 when you have one or more frame widgets that contain more than 9 child widgets because it will result in a duplicate ID conflict.

---

**WIDGET-LEAVE attribute**

A handle, in a trigger associated with an ENTRY event or a LEAVE event, to the widget that had input focus prior to the event.

**Data type:** HANDLE  
**Access:** Readable  
**Applies to:** LAST-EVENT system handle

The WIDGET-ENTER attribute is meaningful only within an ENTRY or LEAVE trigger.

For browse widgets, WIDGET-LEAVE is different depending on whether the browse is editable or read-only. For editable browse widgets, WIDGET-LEAVE contains the handle of the column just left. For read-only browse widgets, WIDGET-LEAVE contains the handle of the field-level widget just left.

---

**Width property**  
*(Windows only; Graphical interfaces only)*

The width of the control-frame and control-frame COM object, in pixels.

**Return type:** INTEGER  
**Access:** Readable/Writeable  
**Applies to:** CONTROL-FRAME widget, COM object

Setting this value changes the WIDTH-CHARS attribute and WIDTH-PIXELS attribute of the corresponding control-frame widget to an equivalent value.

**Note:** References to COM object properties and methods extend the syntax used for referencing widget attributes and methods. For more information, see the “Accessing COM object properties and methods” section on page 1277.

---

**WIDTH-CHARS attribute**

The width of the widget or the display used in the current session, in character units.
WIDTH-PIXELS attribute

The width of the widget or the screen display used in the current session, in pixels.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable/Writable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>BROWSE widget (browse, column, and cell), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SESSION system handle, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget</td>
</tr>
</tbody>
</table>

The attribute is read-only for field groups, and the SESSION handle.

In character mode, the WIDTH-PIXELS attribute must be set before the browse is realized. Attempting to set the attribute after realization of the browse causes a run-time error.
For control-frames, the WIDTH-PIXELS attribute maps to the Width property of the control-frame COM object (ActiveX control container).

For editor widgets, this attribute can set the word wrap margin for the WORD-WRAP attribute. For more information, see the WORD-WRAP attribute reference entry.

For browses, the WIDTH-PIXELS attribute sets the width, in pixels, of the browse without changing the width of any browse column. If you change the value of a browse’s WIDTH-CHARS or WIDTH-PIXELS attribute, the horizontal scrollbar might appear or disappear, which might cause the number of rows that appear in the viewport to change.

For browse columns, the WIDTH-PIXELS attribute sets the width, in pixels, of the browse column without changing the width of the browse.

**WINDOW attribute**

A handle to the window that owns a widget or that contains the owner of a widget.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>HANDLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>BROWSE widget, BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LITERAL widget, MENU widget, MENU-ITEM widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, SUB-MENU widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget</td>
</tr>
</tbody>
</table>

For a menu bar or pop-up menu of a window, the WINDOW and OWNER attributes have the same value. For a window, the WINDOW attribute returns the window’s handle (not its parent’s handle, if any). For a menu bar or pop-up menu of a window, the WINDOW and OWNER attributes have the same value.

**WINDOW-STATE attribute**

The current visual state of a window in the window system.

<table>
<thead>
<tr>
<th>Data type:</th>
<th>INTEGER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access:</td>
<td>Readable/Writeable</td>
</tr>
<tr>
<td>Applies to:</td>
<td>WINDOW widget</td>
</tr>
</tbody>
</table>

The possible values can be expressed as compiler constants. Table 108 lists these values.
You can change the state of a window programmatically by setting the WINDOW-STATE attribute. Note that you can change a window to its maximized state in Windows only.

### WINDOW-SYSTEM attribute

A value that indicates the windowing system the application is using.

**Data type:** CHARACTER  
**Access:** Readable  
**Applies to:** SESSION system handle

- For graphical interfaces in Windows:
  - If the display is set to the Windows XP Theme, and a manifest file is used, the value is "MS-WINXP".
  - If the display is set to the Windows XP Theme, and a manifest file is not used, the value is "MS-WIN95".
  - If the display is set to the Windows Classic Theme, the value is "MS-WIN95".
- For character interfaces, the value is "TTY".
ABL supports an override option that enables applications that need the WINDOW-SYSTEM attribute to return the value of "MS-WINDOWS" for all Microsoft operating systems to do so. To establish this override capability, define the WindowSystem key in the Startup section in the current environment, which might be the registry or an initialization file. If the WindowSystem key is located, the WINDOW-SYSTEM attribute returns the value associated with the WindowSystem key on all platforms.

**WORD-WRAP attribute**

*Graphical interfaces only*

Indicates whether word wrapping is enabled for an editor widget.

**Data type:** LOGICAL

**Access:** Readable/Writeable

**Applies to:** EDITOR widget

If WORD-WRAP is TRUE, the editor automatically breaks lines at any word that crosses the word wrap margin of the text area. If WORD-WRAP is FALSE, the editor continues lines beyond the editor border up to the first hard return, and scrolls as required to keep the entered text in view. The user can scroll left and right to view the entire line. The default value for WORD-WRAP is TRUE.

In graphical interfaces, the word wrap margin is set by the WIDTH-CHARS, WIDTH-PIXELS, or INNER-CHARS attribute. In character interfaces, the word wrap margin is determined by either the WIDTH-CHARS or BUFFER-CHARS attribute, whichever is larger.

In Windows, both the regular editor and the large editor support WORD-WRAP.

**Note:** If the SCROLLBAR-HORIZONTAL attribute is set to TRUE, then WORD-WRAP is automatically set to FALSE. Likewise, if you set the WORD-WRAP attribute to TRUE, then SCROLLBAR-HORIZONTAL is automatically set to FALSE.

You can set this attribute only before the widget is realized.

**WORK-AREA-HEIGHT-PIXELS attribute**

Indicates the height of the work-area in pixels. The work-area is the portion of the Windows desktop that is not hidden by task bars. That is, the dimensions of the work-area are the dimensions of the Windows desktop minus the dimensions of all task bars on the Windows desktop.

**Data type:** INTEGER

**Access:** Readable

**Applies to:** SESSION system handle

In character interfaces, this attribute returns the Unknown value (?).
WORK-AREA-WIDTH-PIXELS attribute

Indicates the width of the work-area in pixels. The work-area is the portion of the Windows desktop that is not hidden by task bars. That is, the dimensions of the work-area are the dimensions of the Windows desktop minus the dimensions of all task bars on the Windows desktop.

Data type: INTEGER
Access: Readable
Applies to: SESSION system handle

On character platforms, this attribute returns the Unknown value (?).

WORK-AREA-X attribute

The starting x-coordinate (the upper left-hand corner) of the work-area in pixels. The work-area is the portion of the Windows desktop that is not hidden by task bars. That is, the dimensions of the work-area are the dimensions of the Windows desktop minus the dimensions of all task bars on the Windows desktop.

Data type: INTEGER
Access: Readable
Applies to: SESSION system handle

On character platforms, this attribute returns the Unknown value (?).

WORK-AREA-Y attribute

The starting y-coordinate (the upper left-hand corner) of the work-area in pixels. The work-area is the portion of the Windows desktop that is not hidden by task bars. That is, the dimensions of the work-area are the dimensions of the Windows desktop minus the dimensions of all task bars on the Windows desktop.

Data type: INTEGER
Access: Readable
Applies to: SESSION system handle

On character platforms, this attribute returns the Unknown value (?).

WRITE() method

Writes data to the socket.
WRITE-CDATA( ) method

Add a CDATA block to an XML document represented by a SAX-writer object.

Return type: LOGICAL
Applies to: SAX-writer object handle

Syntax

```
WRITE-CDATA( value )
```

value
A CHARACTER or LONGCHAR expression evaluating to the value of the CDATA block.

WRITE( ) returns TRUE if the write operation succeeded normally and returns FALSE otherwise. An error can occur if:

- The position parameter is not greater than 0
- The amount of information requested to write exceeds the amount of data in the buffer
- Writing to the socket fails

This method expects buffer to identify a MEMPTR variable which already has a region of memory associated with it. The developer must call the SET-SIZE statement to allocate memory and associate it with a MEMPTR variable. It is the responsibility of the developer to free this memory, also via the SET-SIZE statement. The WRITE method will fail if the size of buffer is less than bytes-to-write.

Even if the WRITE( ) method returns TRUE, not all the bytes may have actually been written. To find out how many bytes were written, check the BYTES-WRITTEN attribute.
Call this method to add character data to the XML document. Character data in an XML document belongs exclusively in leaf nodes. (A leaf node is a bottom node; one that does not have any child nodes in a hierarchical tree structure, like an XML document.) Character data cannot appear outside of the root (document) node. The SAX-writer puts the block into the format of a CDATA section by adding the correct open and close tags. For example:

```xml
<![[CDATA[ your_CDATA_block ]]]>
```

This method does not change the WRITE-STATUS attribute.

**Note:** The CHARACTER data is serialized and not escaped by the SAX-writer.

---

**WRITE-CHARACTERS() method**

Adds character data to an XML document represented by a SAX-writer object.

**Return type:** LOGICAL

**Applies to:** SAX-writer object handle

**Syntax**

```
WRITE-CHARACTERS( { chardata | longchar } )
```

*chardata*

An expression that evaluates to a CHARACTER variable that contains the XML text.

*longchar*

An expression that evaluates to a LONGCHAR variable that contains the XML text.

Call this method to add character data to the XML document. Character data in an XML document belongs exclusively in leaf nodes. (A leaf node is a bottom node; one that does not have any child nodes in a hierarchical tree structure, like an XML document.) Character data cannot appear outside of the root (document) node.

This method sets the status to SAX-WRITE-CONTENT.

The method escapes all special characters according to the XML specification. For example, “<” is changed to “&lt;”.

If the STRICT attribute is TRUE and the call would result in CHARACTER data being written at the document level (that is, outside of the root node), then the method fails.

---

**WRITE-COMMENT() method**

Adds a comment to the XML document represented by a SAX-writer object.
WRITE-DATA-ELEMENT( ) method

 Creates a complete XML node in a SAX-writer object.

 **Return type:** LOGICAL

 **Applies to:** SAX-writer object handle

 **Syntax**

\[
\text{WRITE-DATA-ELEMENT}( \text{name}, \{ \text{chardata} | \text{longchar} \} [ , \text{namespace-URI} ] [ , \text{SAX-attributes-handle} ] )
\]

**name**

A CHARACTER or LONGCHAR expression evaluating to the fully qualified or unqualified name of the element.

**chardata**

An expression that evaluates to a CHARACTER variable that contains the XML text.

**longchar**

An expression that evaluates to a LONGCHAR variable that contains the XML text.

**namespace-URI**

A CHARACTER or LONGCHAR expression evaluating to the URI of the element, or an empty string (""') or the Unknown value (?).

**SAX-attributes-handle**

A HANDLE to a SAX-attributes object. The attributes in the SAX-attributes object are added to the new XML element.

---

WRITE-DATA-ELEMENT( ) method

**Return type:** LOGICAL

**Applies to:** SAX-writer object handle

**Syntax**

\[
\text{WRITE-DATA-ELEMENT( value )}
\]

**value**

A CHARACTER or LONGCHAR expression evaluating to the text of the comment.

Call this method to add a comment node to the XML document. You can add comments at any time. The SAX-writer object creates the comment by enclosing the CHARACTER expression in open and close comment markers (<!-- and -->). For example:

\[
<!-- This is a comment --!>
\]
WRITE-EMPTY-ELEMENT( ) method

Creates a complete XML node. This method call sets the WRITE-STATUS to SAX-WRITE-ELEMENT.

If you use namespace-URI, then the prefix is resolved in the following order:

1. The method attempts to extract the namespace from the name.
2. The method attempts to extract the namespace from a previously declared namespace.
3. The method attempts to generate the default namespace.

If name contains a prefix and namespace-URI is used, and this call is the first instance of the namespace-URI, then the namespace will be added to the element. This is equivalent to calling the DECLARE-NAMESPACE method. If only the name is used and it contains a prefix, then the SAX-writer attempts to resolve the prefix to a namespace.

This technique is logically equivalent to calling the START-ELEMENT, WRITE-CHARACTERS, and END-ELEMENT methods where name and namespace-URI are the parameters of START-ELEMENT and END-ELEMENT, and chardata is the parameter of WRITE-CHARACTERS.

Note that attributes and namespaces cannot be added after you call this method. If you need to add either to the element, then use the START-ELEMENT method.

If the STRICT attribute is TRUE, the FRAGMENT attribute is FALSE, and the invocation would result in more than one document-level element (that is, root node), then the method fails. Also, if STRICT is TRUE, an external DTD has been declared, and the invocation would create the root node, the name used for the DTD declaration must match the name of the root node or the method fails.

See also: DECLARE-NAMESPACE( ) method

WRITE-EMPTY-ELEMENT( ) method

Creates an empty XML node in a SAX-writer object.

Return type: LOGICAL
Applies to: SAX-writer object handle
Syntax

```plaintext
WRITE-EMPTY-ELEMENT( name [, namespace-URI ] [, SAX-attributes-handle ] )
```

name

A CHARACTER or LONGCHAR expression evaluating to the fully qualified or unqualified name of the element.

namespace-URI

A CHARACTER or LONGCHAR expression evaluating to the URI of the element, or an empty string (""") or the Unknown value (?) if the element doesn’t contain a namespace.
WRITE-ENTITY-REF method

Adds an entity reference to the XML document represented by a SAX-writer object.

**Return type:** LOGICAL

**Applies to:** SAX-writer object handle

**Syntax**

```
WRITE-ENTITY-REF ( value )
```

**value**

A CHARACTER or LONGCHAR expression evaluating to the value of the entity reference.
WRITE-EXTERNAL-DTD( ) method

Call this method to add an entity reference to the XML document. You can add entity references at any time during the write.

This method does not change the WRITE-STATUS attribute.

You cannot add entity references using the WRITE-CHARACTERS method because the entity references contain the escapable character “&”. For example, if you add the entity reference fromname with the WRITE-CHARACTERS method, this call, xmlwh:WRITE-CHARACTERS("&fromname;"); produces the invalid value &fromname; in the XML document. However, you can add entity references using the WRITE-FRAGMENT method, since it does not escape special characters.

Do not include the special characters when inserting the reference, only the reference value. For example, xmlwh:entity-reference("fromname") produces &fromname; in the XML document.

See also: WRITE-CHARACTERS( ) method, WRITE-FRAGMENT( ) method

WRITE-EXTERNAL-DTD( ) method

Adds an external Document Type Definition (DTD) reference to an XML document represented by a SAX-writer object.

Return type: LOGICAL

Applies to: SAX-writer object handle

Syntax

WRITE-EXTERNAL-DTD( name, systemID [ , publicID ] )

name

A CHARACTER or LONGCHAR expression evaluating to the fully qualified or unqualified name of the XML document root node.

systemID

A CHARACTER or LONGCHAR expression evaluating to the system ID of the DTD.

publicID

A CHARACTER or LONGCHAR expression evaluating to the public ID of the DTD.

Call this method to add an external DTD reference to the prolog of the XML document.

You can only call this method before the first call of START-ELEMENT. That is, only call this method when the WRITE-STATUS is SAX-WRITE-BEGIN. After the call, the status remains SAX-WRITE-BEGIN.

If the STRICT attribute is TRUE, and you call this method after you create the root element (or when the CREATE-FRAGMENT attribute is TRUE), then the method fails.

The value of name must match the value in the root node. If the STRICT attribute is TRUE and the two values do not match, then the method fails and generates an error.
WRITE-FRAGMENT( ) method

Adds character data to the XML document represented by a SAX-writer object.

Return type: LOGICAL
Applies to: SAX-writer object handle

Syntax

```
WRITE-FRAGMENT( { chardata | longchar | x-noderef } )
```

**chardata**

An expression that evaluates to a CHARACTER variable that contains the XML text.

**longchar**

An expression that evaluates to a LONGCHAR variable that contains the XML text.

**noderef**

A valid X-NODEREF handle that contains the XML text.

Call this method to add un-escaped CHARACTER data to the XML document. This allows the adding of XML fragments to the document without the special characters being escaped to their XML representation. For example, "<" escapes to &lt;. It is up to the developer to ensure that the characters written are proper XML with the correct characters escaped. Even if the STRICT attribute is TRUE, the SAX-writer will not validate what is written.

You can call this method at any time during the write. This method changes the WRITE-STATUS attribute to SAX-WRITE-CONTENT.
WRITE-JSON( ) method

Writes a JSON string from a ProDataSet, a temp-table, or a temp-table buffer object. In the case of the temp-table buffer object, all the records of the temp-table associated with the buffer object are written to the JSON string—not just the one in the buffer.

**Return type:** LOGICAL

**Applies to:** Buffer object handle, ProDataSet object handle, Temp-table object handle

**Syntax**

```plaintext
WRITE-JSON ( mode, { file | stream | stream-handle | memptr | longchar } [, formatted [, encoding [, omit-initial-values ] ] ] )
```

**mode**

A CHARACTER expression that specifies the target for the JSON string. Valid values are “FILE”, “STREAM”, “STREAM-HANDLE”, “MEMPTR”, and “LONGCHAR”.

**file**

A CHARACTER expression that specifies the name of a file to which the AVM writes the JSON string. You can specify an absolute pathname or a pathname relative to the current working directory. If a file with the specified name already exists, the AVM verifies that the file is writable and overwrites the file.

**stream**

A CHARACTER expression that specifies the name of a stream. If you specify the empty string (""), the AVM writes the JSON string to the default unnamed output stream. For WebSpeed, write the JSON string to the WebSpeed-defined output stream (WEBSTREAM).

For more information about using ABL unnamed output streams, see the DEFINE STREAM statement reference entry and the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces*. For more information about using WebSpeed-defined output streams, see *OpenEdge Application Server: Developing WebSpeed Applications*.

**stream-handle**

A HANDLE variable that specifies a stream object handle.

**memptr**

A MEMPTR variable to contain the JSON string in memory. If you do not specify the encoding parameter, the AVM encodes the text written to the MEMPTR as UTF-8. This method allocates the required amount of memory for the JSON string and sets the size of the variable. When you are finished using the MEMPTR, you must free the associated memory, by executing SET-SIZE(memptr) = 0 on the MEMPTR.

**longchar**

A LONGCHAR variable to contain the JSON string in memory.
The AVM saves the JSON string to the LONGCHAR variable in the code page that corresponds to the character encoding you specify in the encoding option. If you do not specify a character encoding for the JSON string, the AVM saves the LONGCHAR variable in UTF-8.

If the LONGCHAR variable's code page is fixed (that is, set using the FIX-CODEPAGE statement) and the fixed code page is not equivalent to the character encoding you specify in the encoding option, the WRITE-JSON( ) method generates an error and returns FALSE. The JSON string is not saved to the LONGCHAR.

formatted

An optional LOGICAL expression where TRUE directs the AVM to format the JSON string in a hierarchical manner using extra white space, carriage returns, and line feeds. The default value is FALSE.

If you specify the Unknown value (?), the method uses the default value of FALSE.

encoding

An optional CHARACTER expression that specifies the name of the character encoding the AVM uses to write the JSON string. The default encoding is "UTF-8".

The encoding name must specify a Unicode transformation format. Valid values are "UTF-8", "UTF-16", "UTF-16BE", "UTF-16LE", "UTF-32", "UTF-32BE", and "UTF-32LE".

Note: If you specify the empty string (""), the Unknown value (?), or the Unknown value (?), the AVM uses the default encoding of UTF-8.

omit-initial-values

An optional LOGICAL expression where TRUE directs the AVM to exclude temp-table fields containing their initial values from the JSON string, and FALSE directs the AVM to include all temp-table field data in the JSON. The default value is FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.

When working with large ProDataSets, omitting fields containing their initial values can yield smaller JSON values, more efficient network transfers, and performance gains with the READ-JSON( ) and WRITE-JSON( ) methods.

This behavior applies both to temp-table fields that have the default initial value for its data type, and for fields that have an initial value set with the ABL INITIAL option.

Although using the omit-initial-values option can give your application performance and resource use improvements, you must be sure that the consumers of the generated JSON string will correctly handle the JSON. The ABL READ-JSON( ) method always populates created records with initial values from the temp-table or ProDataSet definition. Other applications might not do this.

When writing data from a ProDataSet object that contains data-relations, you can nest child rows of a ProDataSet buffer within their parent rows in the resulting JSON string by:

- Setting the NESTED attribute on the Data-relation object handle to TRUE
WRITE-JSON( ) method

- Specifying the NESTED option for the data-relation on the DEFINE DATASET statement
- Specifying the NESTED option in the ADD-RELATION( ) method
- Specifying the FOREIGN-KEY-HIDDEN option in addition to the NESTED option to prevent duplicating the key fields in the child records that are nested within the parent record.

**Note:** If you do not nest child tables, the JSON loses the data relation information. The serialization process also loses any information about key columns.

You cannot write a JSON string from a database buffer.

The following code example defines a static ProDataSet object, attaches its data sources, fills the ProDataSet object, and writes the ProDataSet object to a JSON string in a nested manner:

```plaintext
DEFINE VARIABLE cTargetType AS CHARACTER NO-UNDO.
DEFINE VARIABLE cFile AS CHARACTER NO-UNDO.
DEFINE VARIABLE lFormatted AS LOGICAL NO-UNDO.
DEFINE VARIABLE lRetOK AS LOGICAL NO-UNDO.

DEFINE TEMP-TABLE ttCustomer NO-UNDO LIKE Customer.
DEFINE TEMP-TABLE ttOrder NO-UNDO LIKE Order.
DEFINE TEMP-TABLE ttInvoice NO-UNDO LIKE Invoice.

DEFINE DATASET dsOrderLog FOR ttCustomer, ttOrder, ttInvoice
DATA-RELATION CustOrd FOR ttCustomer,
    ttOrder RELATION-FIELDS(CustNum,CustNum) NESTED
DATA-RELATION OrdInv FOR ttOrder,
    ttInvoice RELATION-FIELDS(OrderNum,OrderNum) NESTED.

DEFINE DATA-SOURCE dsCustomer FOR Customer.
DEFINE DATA-SOURCE dsOrder FOR Order.
DEFINE DATA-SOURCE dsInvoice FOR Invoice.

DATA-SOURCE dsCustomer:FILL-WHERE-STRING = "WHERE Customer.CustNum = 2 ".
DATASET dsOrderLog:FILL().

ASSIGN
    cTargetType = "file"
    cFile = "dset.json"
    lFormatted = TRUE.
    lRetOK = DATASET dsOrderLog:WRITE-JSON(cTargetType, cFile, lFormatted).
```

The following code example defines a static temp-table object, populates the temp-table object (code not shown), and writes the temp-table object to a JSON string:
WRITE-MESSAGE( ) method

Wrote a user message to the current log file.

For an interactive or batch client, the WRITE-MESSAGE( ) method writes the log entries to the log file specified by the LOGFILE-NAME attribute or the Client Logging (-clientlog) startup parameter. For WebSpeed agents and AppServer servers, the WRITE-MESSAGE( ) method writes the log entries to the server log file. For DataServers, the WRITE-MESSAGE( ) method writes the log entries to the log file specified by the DataServer Logging (-dslog) startup parameter.

Note: The DSLOG-MANAGER’s LOGFILE-NAME attribute is read-only.

Return type: LOGICAL
Applies to: DSLOG-MANAGER system handle, LOG-MANAGER system handle

Syntax

```
WRITE-MESSAGE( msg-exp [, subsys-exp ])
```

msg-exp
A character expression or variable representing the message to write to the log file.

subsys-exp
A character expression representing the subsystem identifier to write to the log file. The default is "APPL". You can provide your own subsystem identifier. The subsystem identifier has a character limit 10 characters, and is padded to 10 characters. If you provide a subsystem identifier longer than 10 characters, WRITE-MESSAGE( ) writes only the first 10 characters.

If the WRITE-MESSAGE( ) method succeeds, it returns TRUE. If it fails, it returns FALSE.

See also: ENCODING attribute, FIX-CODEPAGE statement, FOREIGN-KEY-HIDDEN attribute, NESTED attribute, READ-JSON( ) method

```define
define variable cTargetType as character no-undo.
define variable cFile as character no-undo.
define variable lFormatted as logical no-undo.
define variable lRetOK as logical no-undo.

define temp-table ttCust no-undo like customer.

/* code to populate the temp-table */
assign
  cTargetType = "file"
  cFile = "ttCust.json"
  lFormatted = true.
  lRetOK = temp-table ttCust:write-json(cTargetType, cFile, lFormatted).
```
If there is no client log file, the WRITE-MESSAGE( ) method returns FALSE and displays a
warning message indicating this operation is not valid when there is no log file. For an
interactive or batch client, the WRITE-MESSAGE( ) method writes the warning message to the
current output device.

When the client writes messages using the WRITE-MESSAGE( ) method, the component
identifier in the message header is the default component identifier for the client executable
writing to the log. For example, the component identifier for a GUI or character client is “4GL”,
for WebSpeed is “WS”, and for AppServer is “AS”. You can provide your own subsystem
identifier. The default is ”APPL”. The subsystem identifier has a character limit of 10
characters, and is padded to 10 characters.

The following is an example:

```
LOG-MANAGER:WRITE-MESSAGE("Got here, x=" + STRING(x), "DEBUG1").
```

The following line appears in the log file:

```
[04/12/05@13:19:19.742-0500] P-003616 T-001984 1 4GL DEBUG1 Got here, x=5
```

**WRITE-PROCESSING-INSTRUCTION( ) method**

Creates a processing instruction node in an XML document represented by a SAX-writer object.

**Return type:** LOGICAL  
**Applies to:** SAX-writer object handle

**Syntax**

```
WRITE-PROCESSING-INSTRUCTION( target, data )
```

**target**

A CHARACTER or LONGCHAR expression evaluating to the target of the processing
instruction.

**data**

A CHARACTER or LONGCHAR expression that evaluates to the data associated with
the processing instruction.

Call this method to add a processing instruction node to the XML document. You can add
processing instructions at any time. The SAX-writer object creates the processing instruction by
enclosing the CHARACTER expression in open and close processing instruction markers (<? and ?>). For example:

```
<?xml version="1.0"?>
```

This method does not change the WRITE-STATUS attribute.
WRITE-STATUS attribute

The current state of a XML write in a SAX-writer object.

Data type: CHARACTER
Access: Readable
Applies to: SAX-writer object handle

The default value is SAX-WRITE-IDLE.

The possible values WRITE-STATUS can assume are shown in Table 109.

Table 109: WRITE-STATUS attribute values

<table>
<thead>
<tr>
<th>WRITE-STATUS value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAX-WRITE-IDLE</td>
<td>No writing has occurred.</td>
</tr>
<tr>
<td>SAX-WRITE-BEGIN</td>
<td>The START-DOCUMENT method has been called and writing has begun.</td>
</tr>
<tr>
<td>SAX-WRITE-TAG</td>
<td>The writer has written an opening tag. This is the only time that attributes can be inserted with INSERT-ATTRIBUTE and DECLARE-NAMESPACE.</td>
</tr>
<tr>
<td>SAX-WRITE-ELEMENT</td>
<td>The writer is within an element.</td>
</tr>
<tr>
<td>SAX-WRITE-CONTENT</td>
<td>The writer has written the content of an element. In other words, the WRITE-CHARACTERS method has been called.</td>
</tr>
<tr>
<td>SAX-WRITE-COMPLETE</td>
<td>The END-DOCUMENT method has been called and writing is complete.</td>
</tr>
<tr>
<td>SAX-WRITE-ERROR</td>
<td>The SAX-writer could not start or could not continue. Likely causes include: SAX-writer could not be loaded, the XML target could not be written to, a method call fails, etc. This is the status if there is an invalid XML generated while STRICT is TRUE. If the status is SAX-WRITE-ERROR then no attributes can be written and the only method that can be called is RESET.</td>
</tr>
</tbody>
</table>

WRITE-XML( ) method

Writes an XML document from a ProDataSet, temp-table, or temp-table buffer object. In the case of the temp-table buffer object, all the records of the temp-table associated with the buffer object are written to the XML document—not just the one in the buffer. You can write the XML representation of the object with data, schema, or both. If you include schema, it is written using the XML Schema Definition (XSD) language.
When writing data from a ProDataSet object, the AVM writes the current version of data in each row of each table in the ProDataSet object. However, you can also include any before-image data, so that both the current and original versions of the data in each table row are written.

When writing schema for a ProDataSet object, the AVM writes all table definitions as well as relation and index definitions. When writing schema for a temp-table or temp-table buffer object, the AVM writes only table and index definitions.

**Return type:** LOGICAL  
**Applies to:** Buffer object handle, ProDataSet object handle, Temp-table object handle

### Syntax

```
```

- **mode**
  A CHARACTER expression that specifies the target XML document type. Valid values are: “FILE”, “STREAM”, “STREAM-HANDLE”, “MEMPTR”, “HANDLE”, and “LONGCHAR”.

- **file**
  A CHARACTER expression that specifies the name of a file to which the AVM writes the XML document text. You can specify an absolute pathname or a relative pathname (based on the current working directory). If a file with the specified name already exists, the AVM verifies that the file is writeable and overwrites the file.

- **stream**
  A CHARACTER expression that specifies the name of a stream. If you specify the empty string (""), the AVM writes the XML document text to the default unnamed output stream. For WebSpeed, write the XML document text to the WebSpeed-defined output stream (WEBSTREAM).

  For more information about using ABL unnamed output streams, see the DEFINE STREAM statement reference entry and the chapter on alternate I/O sources in *OpenEdge Development: Programming Interfaces*. For more information about using WebSpeed-defined output streams, see *OpenEdge Application Server: Developing WebSpeed Applications*.

- **stream-handle**
  A HANDLE variable that specifies a stream object handle.

- **memptr**
  A MEMPTR variable to contain the XML document text in memory. The method allocates the required amount of memory for the XML document text and sets the size of the variable. When you are finished using the MEMPTR, you must free the associated memory by executing SET-SIZE(memptr) = 0 on the MEMPTR.
WRITE-XML( ) method

**handle**

An X-document object handle or X-noderef object handle. If the specified handle contains XML text, the AVM deletes the existing text first.

**longchar**

A LONGCHAR variable to contain the XML document text in memory.

The AVM saves the XML document text to the LONGCHAR variable in the code page that corresponds to the character encoding you specify in the `encoding` option. If you do not specify a character encoding for the XML document text, the AVM saves the LONGCHAR variable in UTF-8.

If the LONGCHAR variable’s code page is fixed (that is, set using the FIX-CODEPAGE statement) and the fixed code page is not equivalent to the character encoding you specify in the `encoding` option, the WRITE-XML( ) method returns an error and the XML document is not saved to the LONGCHAR.

**formatted**

An optional LOGICAL expression where TRUE directs the AVM to format the XML document text in a hierarchical manner using extra white space, carriage returns, and line feeds. The default value is FALSE.

If you specify the Unknown value (?), the method uses the default value of FALSE.

**encoding**

An optional CHARACTER expression that specifies the name of the character encoding the AVM uses to write the XML document text. The default encoding is UTF-8.

The encoding name must be an Internet Assigned Numbers Authority (IANA) name supported by the ABL XML Parser. For a list of supported IANA encodings and their corresponding ABL code pages, see Table 78 in the `ENCODING` attribute reference entry.

**Note:** The AVM records this character encoding in the encoding declaration in the XML document’s prologue. If you specify the empty string ("") or the Unknown value (?), the AVM uses the default encoding of UTF-8. In this case, the AVM does not record the character encoding in the XML document’s encoding declaration.

If `mode` is HANDLE, the X-document’s `ENCODING` attribute is also set.

**schema-location**

An optional CHARACTER expression that specifies the name of an external XML Schema file. The method uses this value to set the `xsi:schemaLocation` or `xsi:noNamespaceSchemaLocation` attribute in the XML document. If the ProDataSet or temp-table object’s NAMESPACE-URI attribute is the empty string ("") or the Unknown value (?), the method adds the `xsi:noNamespaceSchemaLocation` attribute in the XML document and sets it to this value. If the NAMESPACE-URI attribute is not the empty string ("") or the Unknown value (?), the method adds the `xsi:schemaLocation` attribute to the XML document with a value of "namespace-uri<space>schema-location". The default value is the Unknown value (?).
**WRITE-XML( ) method**

**Note:** You must provide the location of an actual XML Schema file. Consider using the WRITE-XMLSCHEMA( ) method to generate the XML Schema file.

If you specify *write-xmlschema* as TRUE, you cannot specify *schema-location*.

*write-xmlschema*

An optional LOGICAL expression where TRUE directs the AVM to write the ProDataSet or temp-table object’s relational structure as in-line XML Schema along with the data, and FALSE directs the AVM to write only the data. The default value is FALSE.

If you specify TRUE, you cannot specify *schema-location*. If you specify FALSE, you must also specify *min-xmlschema* as FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.

**Note:** If you specify TRUE and the NAMESPACE-URI attribute value for a temp-table buffer within a ProDataSet object is different than that of the ProDataSet object, the method creates a separate XML Schema file for the temp-table definition. The namespace URI for the temp-table is imported into the ProDataSet schema, with a schemaLocation pointing to a separate XML Schema file containing the temp-table definition. Multiple namespaces are supported only when mode is “FILE”. If the ProDataSet object contains multiple namespaces and mode is not “FILE”, the method generates an error and returns FALSE.

*min-xmlschema*

An optional LOGICAL expression where TRUE directs the AVM to write the minimum amount of schema when it writes the XML Schema representation of the object, and FALSE directs the AVM to write the complete schema including ABL-specific schema attributes. The default value is FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.

When TRUE, ABL-specific schema information (such as, field format, non-unique indexes, and so on) is omitted from the XML Schema. If the ABL data type of the temp-table field is not the default ABL data type for the XML Schema type, the AVM writes the prodata:dataType XML Schema attribute for the field. If the initial value of the temp-table field is TODAY, NOW, or UNKNOWN (and UNKNOWN is not the default initial value for the field’s data type), the AVM writes the prodata:initia1 XML Schema attribute for the field.

When TRUE, the XML Schema will contain any ABL-specific XML Schema attributes needed to define the data relations for a ProDataSet.

If you specify *write-xmlschema* as FALSE, you must also specify *min-xmlschema* as FALSE.

*write-before-image*

An optional LOGICAL expression where TRUE directs the AVM to write any before-image table data and error information in addition to the ProDataSet object data, and FALSE directs the AVM to write only the ProDataSet object data. The default value is FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.
**omit-initial-values**

An optional LOGICAL expression where TRUE directs the AVM to exclude temp-table fields containing their initial values from the XML document, and FALSE directs the AVM to include all temp-table field data in the XML. The default value is FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.

When working with large ProDataSets, omitting initial values in records can yield smaller XML documents, more efficient network transfers, and performance gains with the READ-XML( ) and WRITE-XML( ) methods.

The XML Schema indicates what the initial values for the omitted temp-table fields are, thus ensuring round trip of the XML data from and to OpenEdge applications. The READ-XML( ) method assigns the field its initial value when the field is not present in the XML document.

This behavior applies both to temp-table fields that have the default initial value for its data type and for fields that have an initial value set with the ABL INITIAL option.

Although using the omit-initial-values option can give your application performance and resource use improvements, you need to be sure that the consumers of the generated XML document will correctly handle the XML. The ABL READ-XML( ) method will always populate created records with initial values from the temp-table or ProDataSet definition. Other applications might not do this.

For example, .NET can read an XML Schema and XML data document into a dynamic ADO .NET DataSet using its ReadXmlSchema() and ReadXml( ) APIs, but missing elements are always interpreted as a null (unknown in ABL terms) DataColumn in the DataTable. They do recognize the initial value definition in the XML Schema when creating rows in the DataTable directly (initial value in the XML Schema gets translated to the DefaultValue property on the DataColumn), but do not with ReadXml().

**Note:** For an array field to be omitted, each element of the array must contain the initial value.

You can specify how a temp-table column is represented in XML (that is, as an ELEMENT, ATTRIBUTE, or TEXT) by:

- Setting the XML-NODE-TYPE attribute on the Buffer-field object handle
- Specifying the XML-NODE-TYPE option on the DEFINE TEMP-TABLE statement

When writing data from a ProDataSet object that contains data-relations, you can nest child rows of a ProDataSet buffer within their parent rows in the resulting XML document by:

- Setting the NESTED attribute on the Data-relation object handle to TRUE
- Specifying the NESTED option for the data-relation on the DEFINE DATASET statement
- Specifying the NESTED option in the ADD-RELATION( ) method
- Specifying the FOREIGN-KEY-HIDDEN option to prevent duplicating the key fields in the child records that are nested within the parent record.

ABL has pairs of attributes with overlapping purposes in how the AVM outputs XML data:
WRITE-XML( ) method

- SERIALIZE-HIDDEN and XML-NODE-TYPE
- SERIALIZE-NAME and XML-NODE-NAME

Refer to the attribute entries for a full description of their interaction.

If your temp-tables contain array fields, third party products utilizing the XML might not map the ABL array field to an array column or object. For best interoperability with third party products, flatten array fields into individual fields.

You cannot write an XML document from a database buffer.

---

**Note:** When executing the WRITE-XML( ) method on a temp-table or ProDataSet, and the default buffer of one of the contained temp-tables is available, there is no guarantee as to the state of that buffer after the method finishes executing. The record buffer may not be available. If default buffer availability is an issue, it is suggested that a named buffer be used with this method. A named buffer can be created with the DEFINE BUFFER statement.

---

The following code example defines a static ProDataSet object, attaches its data sources, fills the ProDataSet object, and writes the ProDataSet object to an XML document in a nested manner:
The following code example defines a static temp-table object, populates the temp-table object (code not shown), and writes the temp-table object to an XML document:
WRITE-XMLSCHEMA( ) method

WRITE-XMLSCHEMA( ) method

See also: ENCODING attribute, FIX-CODEPAGE statement, FOREIGN-KEY-HIDDEN attribute, NAMESPACE-PREFIX attribute, NAMESPACE-URI attribute, NESTED attribute, READ-XML( ) method, READ-XMLSCHEMA( ) method, SERIALIZE-HIDDEN attribute, SERIALIZE-NAME attribute, WRITE-XMLSCHEMA( ) method, XML-NODE-NAME attribute, XML-NODE-TYPE attribute

WRITE-XMLSCHEMA( ) method

Writes an XML representation of the definition of a ProDataSet, temp-table, or temp-table buffer object (that is, an XML Schema file). The XML Schema is written using the XML Schema Definition (XSD) language.

When writing schema for a ProDataSet object, the AVM writes all table definitions as well as relation and index definitions. When writing schema for a temp-table or temp-table buffer object, the AVM writes only table and index definitions.

Return type: LOGICAL
Applies to: Buffer object handle, ProDataSet object handle, Temp-table object handle

Syntax

WRITE-XMLSCHEMA ( mode,
    { file | stream | stream-handle | memptr | handle | longchar }
    [, formatted [, encoding [, min-xmlschema
WRITE-XMLSCHEMA() method

mode

A CHARACTER expression that specifies the target XML Schema document type. Valid values are: “FILE”, “STREAM”, “STREAM-HANDLE”, “MEMPTR”, “HANDLE”, and “LONGCHAR”.

file

A CHARACTER expression that specifies the name of a file to which the AVM writes the XML Schema document text. You can specify an absolute pathname or a relative pathname (based on the current working directory). If a file with the specified name already exists, the AVM verifies that the file is writeable and overwrites the file.

stream

A CHARACTER expression that specifies the name of a stream. If you specify the empty string (""), the AVM writes the XML Schema document text to the default unnamed output stream. For WebSpeed, write the XML Schema document text to the WebSpeed-defined output stream (WEBSTREAM).

For more information about using ABL unnamed output streams, see the DEFINE STREAM statement reference entry and the chapter on alternate I/O sources in OpenEdge Development: Programming Interfaces. For more information about using WebSpeed-defined output streams, see OpenEdge Application Server: Developing WebSpeed Applications.

stream-handle

A CHARACTER expression that specifies a stream object handle.

memptr

A MEMPTR variable to contain the XML Schema document text in memory. The method allocates the required amount of memory for the XML document text and sets the size of the variable. When you are finished using the MEMPTR, you must free the associated memory by executing SET-SIZE(memptr) = 0 on the MEMPTR.

handle

An X-document object handle or X-noderef object handle. If the specified handle contains XML text, the AVM deletes the existing text first.

longchar

A LONGCHAR variable to contain the XML Schema document text in memory.

The AVM saves the XML Schema document text to the LONGCHAR variable in the code page that corresponds to the character encoding you specify in the encoding option. If you do not specify a character encoding for the XML Schema document text, the AVM saves the LONGCHAR variable in UTF-8.

If the LONGCHAR variable’s code page is fixed (that is, set using the FIX-CODEPAGE statement) and the fixed code page is not equivalent to the character encoding you specify in the encoding option, the WRITE-XMLSCHEMA() method returns an error and the XML Schema document is not saved to the LONGCHAR.
formatted

An optional LOGICAL expression where TRUE directs the AVM to format the XML Schema document text in a hierarchical manner using extra white space, carriage returns, and line feeds. The default value is FALSE.

If you specify the Unknown value (?), the method uses the default value of FALSE.

encoding

An optional CHARACTER expression that specifies the name of the character encoding the AVM uses to write the XML Schema document text. The default encoding is UTF-8.

The encoding name must be an Internet Assigned Numbers Authority (IANA) name supported by the ABL XML Parser. For a list of supported IANA encodings and their corresponding ABL code pages, see Table 78 in the ENCODING attribute reference entry.

Note: The AVM records this character encoding in the encoding declaration in the XML document’s prologue. If you specify the empty string (“”) or the Unknown value (?), the AVM uses the default encoding of UTF-8. In this case, the AVM does not record the character encoding in the XML document’s encoding declaration.

If mode is HANDLE, the X-document’s ENCODING attribute is also set.

min-xmlschema

An optional LOGICAL expression where TRUE directs the AVM to write the minimum amount of schema for the object, and FALSE directs the AVM to write the complete schema including ABL-specific schema attributes. The default value is FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.

When TRUE, ABL-specific schema information (such as, field format, non-unique indexes, and so on) is omitted from the XML Schema. If the ABL data type of the temp-table field is not the default ABL data type for the XML Schema type, the AVM writes the prodata: dataType XML Schema attribute for the field. If the initial value of the temp-table field is TODAY, NOW, or UNKNOWN (and UNKNOWN is not the default initial value for the field’s data type), the AVM writes the prodata: initial XML Schema attribute for the field.

When TRUE, the XML Schema will contain any ABL-specific XML Schema attributes needed to define the data relations for a ProDataSet.

omit-initial-values

An optional LOGICAL expression where TRUE directs the AVM to indicate in the XML Schema that the fields are optional in the XML instance document, and FALSE directs the AVM to indicate in the XML Schema that the fields are required in the XML instance document. The default value is FALSE. If you specify the Unknown value (?), the method uses the default value of FALSE.

This behavior applies both to temp-table fields that have the default initial value for its data type and for fields that have an initial value set with the ABL INITIAL option.
If the NAMESPACE-URI attribute value for a temp-table within a ProDataSet object is different than that of the ProDataSet object, the method creates a separate XML Schema file for the temp-table definition. The namespace URI for the temp-table is imported into the ProDataSet schema, with a schemaLocation pointing to a separate XML Schema file containing the temp-table definition. Multiple namespaces are supported only when mode is “FILE”. If you specify multiple namespaces and mode is not “FILE”, the method generates an error and returns FALSE.

You can specify how a temp-table column is represented in XML Schema (that is, as an ELEMENT, ATTRIBUTE, or TEXT) by:

- Setting the XML-NODE-TYPE attribute on the Buffer-field object handle
- Specifying the XML-NODE-TYPE option on the DEFINE TEMP-TABLE statement

When writing schema for a ProDataSet object that contains data-relations, you can nest child rows of a ProDataSet buffer definition within their parent buffer definitions in the resulting XML Schema by:

- Setting the NESTED attribute on the Data-relation object handle to TRUE
- Specifying the NESTED option for the data-relation on the DEFINE DATASET statement
- Specifying the NESTED option in the ADD-RELATION( ) method
- Specifying the FOREIGN-KEY-HIDDEN option to prevent duplicating the key fields in the child records that are nested within the parent record

If your temp-tables contain array fields, third party products utilizing the XML Schema might not map the ABL array field to an array column or object. For best interoperability with third party products, flatten array fields into individual fields.

You cannot write an XML representation of the schema for a database buffer.

The following code example defines a static ProDataSet object and writes the ProDataSet object schema to an XML Schema file:
The following code example defines a static temp-table object, and writes the temp-table object schema to an XML Schema file:

```sql
DEFINE VARIABLE cTargetType AS CHARACTER NO-UNDO.
DEFINE VARIABLE cFile AS CHARACTER NO-UNDO.
DEFINE VARIABLE lFormatted AS LOGICAL NO-UNDO.
DEFINE VARIABLE cEncoding AS CHARACTER NO-UNDO.
DEFINE VARIABLE lMinSchema AS LOGICAL NO-UNDO.
DEFINE VARIABLE lRetOK AS LOGICAL NO-UNDO.

DEFINE TEMP-TABLE ttCustomer NO-UNDO LIKE Customer.
DEFINE TEMP-TABLE ttOrder NO-UNDO LIKE Order.
DEFINE TEMP-TABLE ttInvoice NO-UNDO LIKE Invoice.

DEFINE DATASET DSET FOR ttCustomer, ttOrder, ttInvoice
  DATA-RELATION CustOrd FOR ttCustomer,
    ttOrd RELATION-FIELDS(CustNum, CustNum) NESTED
  DATA-RELATION OrdInv FOR ttOrder,
    ttInv RELATION-FIELDS(OrderNum, OrderNum) NESTED.

ASSIGN
  cTargetType = "file"
  cFile = "cust-ord-inv.xsd"
  lFormatted = TRUE
  cEncoding = ?
  lMinSchema = FALSE.

lRetOK = DATASET DSET:WRITE-XMLSCHEMA(cTargetType, cFile, lFormatted, cEncoding, lMinSchema).
```

See also: ENCODING attribute, FIX-CODEPAGE statement, FOREIGN-KEY-HIDDEN attribute, NAMESPACE-PREFIX attribute, NAMESPACE-URI attribute, NESTED attribute, READ-XML( ) method.
X attribute

The pixel location of the left edge of a widget relative to the left edge of the parent widget or the display. The pixel location of the mouse cursor relative to the left edge of the display (for the last mouse event).

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget (browse and column), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LAST-EVENT system handle, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

This attribute is read-only for field groups, browse cells, and the LAST-EVENT handle.

For all user interface widgets except windows, the X attribute specifies the location, in pixels, of the left edge of the widget relative to the left edge of its parent widget. In windows, it is the location of the left edge of the window relative to the left edge of the display.

For a browse column, the X attribute returns the Unknown value (?) if the column is hidden.

For control-frames, the X attribute maps to the Left property of the control-frame COM object (ActiveX control container).

For the LAST-EVENT handle, the X attribute returns the pixel location of a mouse event relative to the left edge of the current frame.

This attribute is functionally equivalent to the COLUMN attribute.

X-DOCUMENT attribute

Contains the X-document object handle of an XML document posted to the transaction server or the Unknown value (?) if there isn’t one.
XCODE-SESSION-KEY attribute

Data type: HANDLE
Access: Readable
Applies to: WEB-CONTEXT system handle

Notes
• The XCODE-SESSION-KEY attribute contains the encryption key used by the COMPILE statement for the current session. The attribute must contain the same key used with the XCODE utility. The attribute does not have a default or initial value. To unset the attribute, set it with the Unknown value (?
). Because the attribute contains an encryption key, any attempt to read the attribute is a compiler error.

Notes
• Both the XCODE utility and this attribute have an eight-character limit for keys. However, neither the utility or the attribute issues a warning or error if the key is longer. Instead, the utility and attribute use the first eight characters and ignore additional characters.

Notes
• The XCODE utility does not perform code page conversions and does not use the -cpinternal parameter when encrypting files. Therefore, the source code and key will use the default codepage of the operating system where you run the XCODE utility. If a different codepage is in effect where XCODE-SESSION-KEY is set, then codepage conversions may prevent the attribute key from matching the XCODE utility key and the compile fails. To prevent this case, use only US-ASCII characters, which are found in all code pages below code point 128.

Notes
• You cannot use XCODE with the XREF, XREF-XML, STRING-XREF, or LISTING options together. Also, if the DEBUG-LIST option is used with an encrypted source file, the resulting debug file will only contain a notice that the source file is encrypted.

Notes
• The LIST-QUERY-ATTRS and LIST-SET-ATTRS functions do not return the XCODE-SESSION-KEY attribute when given a SECURITY-POLICY handle.

XML-DATA-TYPE attribute

Returns the XML Schema data type for the buffer-field object.

Data type: CHARACTER
Access: Readable/Writeable
Applies to: Buffer-field object handle

The XML Schema data type must be compatible with the ABL data type for the field.

For more information about the ABL XML data type mapping rules, see OpenEdge Development: Working with XML.
If the temp-table schema was created from an XML Schema, this attribute is the same as the `xsd:type` attribute in the XML Schema.

**XML-NODE-NAME attribute**

Indicates the name of the XML element or attribute representing the ProDataSet, the temp-table, the temp-table buffer, or the temp-table buffer-field object name in an XML document.

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Buffer object handle, Buffer-field object handle, ProDataSet object handle, Temp-table object handle

This attribute’s purpose overlaps with the SERIALIZE-NAME attribute. Because of this overlap, the attributes interact as follows:

- The READ-XML( ) and WRITE-XML( ) methods always use the XML-NODE-NAME attribute value. If you set a value for the XML-NODE-NAME attribute, it keeps that value regardless of how you set the SERIALIZE-NAME attribute.
- If you do not set the XML-NODE-NAME attribute and set the SERIALIZE-NAME attribute, the AVM sets XML-NODE-NAME equal to SERIALIZE-NAME.
- If you do not set either attribute, the AVM sets both to the ABL object name.

This attribute allows you to work around ABL names that use illegal XML characters or to work around XML element or attribute names that are reserved words in ABL.

For more information about using this attribute, see *OpenEdge Development: Working with XML*.

**See also:** READ-XML( ) method, SERIALIZE-NAME attribute, WRITE-XML( ) method

**XML-NODE-TYPE attribute**

The XML node type of the buffer-field object, which lets you specify how a buffer field is represented in XML and XML Schema. Valid XML node types are "ATTRIBUTE", "ELEMENT", "HIDDEN", and "TEXT".

**Data type:** CHARACTER  
**Access:** Readable/Writeable  
**Applies to:** Buffer-field object handle

Table 110 lists the valid XML node types.
The XML node type of a buffer field that represents an array must be either "ELEMENT" or "HIDDEN".

This attribute’s purpose overlaps with the SERIALIZE-HIDDEN attribute. Because of this overlap, the attributes interact as follows:

- The WRITE-XML( ) method always uses the XML-NODE-TYPE attribute value. If you set a value for the XML-NODE-TYPE attribute, it keeps that value regardless of how you set the SERIALIZE-HIDDEN attribute.
- If you do not set the XML-NODE-TYPE attribute and set the SERIALIZE-HIDDEN attribute to TRUE, the AVM sets XML-NODE-TYPE to "HIDDEN".
- If you do not set the XML-NODE-TYPE attribute and set the SERIALIZE-HIDDEN attribute to FALSE, the AVM sets XML-NODE-TYPE to "ELEMENT".
- If you do not set either attribute, the AVM sets XML-NODE-TYPE to "ELEMENT" and sets SERIALIZE-HIDDEN to FALSE.

See also: SERIALIZE-HIDDEN attribute, WRITE-XML( ) method, WRITE-XMLSCHEMA( ) method

### XML-Schema-Path attribute
#### (WebSpeed Only)

A delimiter-separated list of directory paths for the XML Document Type Definition (DTD) associated with a particular XML document in a WebSpeed environment. Searched if the XML document contains a relative path to the DTD.
**XML-SUPPRESS-NAMESPACE-PROCESSING attribute**

**(WebSpeed Only)**

Specifies whether to suppress namespace processing.

<table>
<thead>
<tr>
<th><strong>Data type:</strong></th>
<th>CHARACTER</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access:</strong></td>
<td>Readable/Writeable</td>
</tr>
<tr>
<td><strong>Applies to:</strong></td>
<td>WEB-CONTEXT system handle</td>
</tr>
</tbody>
</table>

Almost identical to the SUPPRESS-NAMESPACE-PROCESSING attribute of the X-document handle. For more information on SUPPRESS-NAMESPACE-PROCESSING, see the reference entry for the SUPPRESS-NAMESPACE-PROCESSING attribute.
What XML-SUPPRESS-NAMESPACE-PROCESSING avoids

In WebSpeed, the first time you access the X-document handle or any of its attributes, either directly or indirectly, you trigger a load of the document, which precedes your access. For example, if you set the SUPPRESS-NAMESPACE-PROCESSING attribute of X-document (of WEB-CONTEXT) before accessing X-document (of WEB-CONTEXT) or any of its attributes, when the document arrives, WebSpeed first loads the document, then sets SUPPRESS-NAMESPACE-PROCESSING to your value. So at load time, SUPPRESS-NAMESPACE-PROCESSING might not be set to your value, which might cause document validation to fail.

By contrast, if you set XML-SUPPRESS-NAMESPACE-PROCESSING instead of SUPPRESS-NAMESPACE-PROCESSING, when the document arrives, WebSpeed assigns the value of XML-SUPPRESS-NAMESPACE-PROCESSING to SUPPRESS-NAMESPACE-PROCESSING before doing anything else. Even if this triggers a load of the document, SUPPRESS-NAMESPACE-PROCESSING already contains your value, so WebSpeed is able to validate your document.

How to use XML-SUPPRESS-NAMESPACE-PROCESSING

In WebSpeed, instead of accessing SUPPRESS-NAMESPACE-PROCESSING of X-document (of WEB-CONTEXT), access XML-SUPPRESS-NAMESPACE-PROCESSING (of WEB-CONTEXT). For example, if you want a WebSpeed application to turn namespace processing off (perhaps in response to a Web request), instead of having the application assign FALSE to SUPPRESS-NAMESPACE-PROCESSING of X-document (of WEB-CONTEXT) have the application assign FALSE to XML-SUPPRESS-NAMESPACE-PROCESSING (of WEB-CONTEXT).

For more information on accessing XML documents using the SAX and X-document interfaces, see OpenEdge Development: Working with XML.

Y attribute

The pixel location of the top edge of the widget relative to the top edge of the parent widget or the display. The pixel location of the mouse cursor relative to the top edge of the display (for the last mouse event). This attribute is functionally equivalent to the ROW attribute.

Data type: INTEGER
Access: Readable/Writeable
Applies to: BROWSE widget (browse and cell), BUTTON widget, COMBO-BOX widget, CONTROL-FRAME widget, DIALOG-BOX widget, EDITOR widget, FIELD-GROUP widget, FILL-IN widget, FRAME widget, IMAGE widget, LAST-EVENT system handle, LITERAL widget, RADIO-SET widget, RECTANGLE widget, SELECTION-LIST widget, SLIDER widget, TEXT widget, TOGGLE-BOX widget, WINDOW widget

This attribute is read-only for field groups, browse cells, and the LAST-EVENT handle.

For all user interface widgets except windows, the Y attribute specifies the location, in pixels, of the top edge of the widget relative to the top edge of its parent widget. In windows, it is the location of the top edge of the window relative to the top edge of the display.
For a browse column, the Y attribute returns the Unknown value (?) if the column is hidden.

For control-frames, the Y attribute maps to the Top property of the control-frame COM object (ActiveX control container).

For the LAST-EVENT handle, the Y attribute returns the pixel location of a mouse event relative to the top edge of the current frame.

YEAR-OFFSET attribute

The current start date for the ABL two-digit year-range of 100 years. Use this attribute to display DATE, DATETIME, and DATETIME-TZ data when the format specifies a two-digit year.

Data type: INTEGER
Access: Readable/Writeable
Applies to: SESSION system handle

Typical values are 1920 or 1950. This attribute provides the same functionality as the Year Offset (-yy) parameter. The default value is 1950.
YEAR-OFFSET attribute
Handle-based Object Events Reference

Events are run-time conditions that cause the ABL Virtual Machine (AVM) to respond by executing specified ABL code or by activating certain system behaviors. Events can occur directly as a result of ABL, user, or other external actions that affect the application. However events occur, the resulting executed code or activated behavior is referred to as event driven.

There are a number of factors that determine how ABL interprets events. The most important factor is the type of widget or handle receiving the event. Some widget types have default system actions in response to certain events. For example, the default system action for the A event on a fill-in widget is to insert the letter A into the fill-in at the current cursor location; however, there is no default system action for the A event on a button widget.

Different widget attribute settings determine how ABL interprets and prioritizes events. If you enable a widget for direct manipulation, direct manipulation events take priority over all other events. For example, if you write a trigger for a CHOOSE event and another for a SELECT event on a selectable widget, the AVM only executes the SELECT event trigger when you click on that widget.

This section describes the following topics for user-interface events only:

- **Introduction to ABL events**
- **Event tables**

You may consider an event to be supported for all interfaces, on all operating systems, and for SpeedScript unless otherwise indicated in the reference entry. User-interface events do not apply to SpeedScript programming.

For information on the following events, see the relevant documentation:

- **DDE-NOTIFY** — *OpenEdge Development: Programming Interfaces*
- **PROCEDURE-COMPLETE** — *OpenEdge Application Server: Developing AppServer Applications*
WEB-NOTIFY — *OpenEdge Application Server: Developing WebSpeed Applications*

The following descriptions refer to both compile-time and run-time behavior, features that the language generally supports and determines at compile time and actions directed by using these features at run time. When describing compile-time features or actions, this section references ABL or the ABL compiler. When describing ABL or event-driven actions taken at run time, this section references the AVM.

**Introduction to ABL events**

This section covers the following topics:

- Event priority
- Applying events
- Triggers and low-level keyboard events

**Event priority**

The priority of events is an important concept. For any mouse or keyboard action on a widget, ABL generates a single event. Thus, certain events take priority over others that are generated by the same keyboard or mouse action for the same widget. Without direct manipulation, the priority (first to last) of keyboard events is key label, key function, and then high-level widget events such as CHOOSE. The priority of mouse events is three-button, portable, and then high-level widget events. Within three-button and portable mouse events, low-level mouse events (up, down) take priority over high-level mouse events (click, double-click). For more information on keyboard and mouse event priority, see the chapter on handling user input in *OpenEdge Development: Programming Interfaces*.

**Applying events**

You can apply any event to any widget using the APPLY statement. Depending on the event-widget pair, the APPLY statement may or may not perform the default system action. Regardless of whether there is a default system action associated with an event-widget pair, you can write a trigger for the pair. The APPLY statement executes a trigger associated with an event-widget pair. If the event-widget pair has a default system action, that action occurs before or after the trigger executes, depending on the event.

The APPLY statement also serves as a communications/dispatch mechanism between procedures in an application. You can define a trigger for an event-procedure pair. For example:

```abl
ON CLOSE OF THIS-PROCEDURE DO:
  APPLY "CLOSE" TO WINDOW-1.
END.
```

To define a trigger for a procedure, specify any ABL event in an ON statement for a procedure handle. This capability allows you to encapsulate functionality in a procedure. To access that functionality, simply use the APPLY statement to apply the appropriate event to the handle of the procedure. For more information, see the APPLY statement reference entry.
When working with browse widgets, you can apply events to the browse widget and to a browse cell in the currently focused row. For example:

```
ON CHOOSE OF button1 DO:
   APPLY "ENTRY" TO my-browse IN FRAME a.
   /* Code to focus a particular row in the browse. */
   APPLY "ENTRY" TO column3 IN BROWSE my-browse.
END.
```

Since a browse cell is the intersection of a column and row, referencing the column name references the intersection of that column and the currently focused row.

**Note:** The most flexible technique for encapsulating functionality in a procedure is to define and call internal procedures of a persistent procedure.

### Triggers and low-level keyboard events

Some low-level keyboard events cannot have associated triggers and maintain their default behavior at the same time. In general, if the AVM gets an event from the user interface system (UIS) that has a trigger associated with it, the AVM handles the default behavior and tells the UIS to ignore the event. This allows the AVM to cancel the default behavior in response to a RETURN NO-APPLY invoked by the trigger.

However, there are some low-level keyboard events for which the AVM does not handle the default behavior. These include the cursor keys, especially. When the AVM gets one of these events with an associated trigger, it tells the UIS to ignore the event as usual, but because the AVM does not handle the default behavior for the event, the standard UIS behavior is lost, as well. Thus, a cursor key event (for example, CURSOR-UP) that has an associated trigger does not move the cursor.

Note that for many low-level events, such as mouse button and printable character events in fill-in fields and editors, the AVM **does** provide the default handling. Triggers on these events have no effect on the default event behavior unless they return NO-APPLY. The same is true of keyboard events that generate high-level functions, such as TAB and RETURN.

For those low-level, non-printable, keyboard events that are not handled by the AVM, do not associate triggers with them unless you do not want the default behavior of the event. For those low-level events that have no standard UIS behavior (such as, programmable function keys) triggers have no negative effects, and in fact, are very useful in defining a program action. In general, check any questionable low-level events in a test procedure both before and after associating triggers with them to see if any standard behavior is affected. An empty trigger block is sufficient to detect differences in behavior. For example:

```
ON event ANYWHERE DO: END.
```
Event tables

The tables in this section describe user interface events, the user actions that generate the events, and widgets that have default behavior for the events. The term **field-level widgets** refers to any widgets that can be part of a field group in a frame: fill-ins, sliders, selection lists, toggle boxes, radio sets, editors, rectangles, images, text, buttons, combo boxes, and browse widgets. Frames, dialog boxes, windows, menus (including menu bars and pop-up menus), sub-menus, and menu items can also receive events. Note that there is frequently a distinction made between a browse widget and a single cell in an updateable browse. For the most part, a browse cell behaves as a fill-in widget.

The event tables in this section describe the following kinds of events:

- **Keyboard events**
- **Mouse events**
- **High-level widget events**
- **Direct manipulation events**
- **Developer events**
- **Socket events**
- **ProDataSet events**

**Keyboard events**

ABL makes all keyboard actions available as events that you can specify by either key label or key function. You can write triggers for these keyboard events, and associate these triggers with any field-level widget that receives input focus. For a complete list of key label and key function names, and information on how to use them, see the chapter on handling user input in *OpenEdge Development: Programming Interfaces*.

Keyboard events have default effects depending on the widget that receives the event. For example, the “A” key label event displays an uppercase “A” in a fill-in or editor widget, but has no default effect when applied to a button. ABL organizes some key function events into several classes that have default effects on selected groups of widgets. ABL also provides special keyboard events to write default triggers on classes of keys. You can use these default events to write a trigger for all keys in a particular class for which you have not defined a key label or key function event trigger.

**Main classes of key function events**

ABL supports three main classes of key function events:

- **Universal key function events** — Apply to all user-interface widgets except menus, sub-menus, and menu items
- **Navigation key function events** — Apply to those field-level widgets that can receive focus
- **Field editing key function events** — Apply to fill-ins and browse cells
Table 111 describes universal key function events.

Default keyboard events

ABL provides two keyboard events that you can use to write default triggers. Table 114 describes these events.

Table 114: Default keyboard events

<table>
<thead>
<tr>
<th>Event</th>
<th>Affected widgets</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANY-KEY</td>
<td>Browse, browse cell, button, combo box, editor, fill-in, radio set, selection list, slider, toggle box</td>
<td>Executes for any keyboard event for which the user has not defined a specific trigger.</td>
</tr>
<tr>
<td>ANY-PRINTABLE</td>
<td>Browse, browse cell, button, combo box, editor, fill-in, radio set, selection list, slider, toggle box</td>
<td>Executes for any keyboard event that normally produces a printable character.</td>
</tr>
</tbody>
</table>
Mouse events

ABL supports two types of mouse events—portable and three-button events. You can use portable mouse events to associate triggers with logical actions of any mouse. You can use the three-button mouse events to associate triggers with specific physical actions of a three-button mouse.

The following tables reference portable mouse buttons for portable mouse events and physical mouse buttons for three-button mouse events. For more information on the mapping between portable and physical mouse buttons and how the AVM processes mouse events, see the chapter on handling user input in OpenEdge Development: Programming Interfaces.

Portable mouse events

Table 115 lists the mouse events that apply to all mice, no matter how the buttons are configured.

Table 115: Portable mouse events

<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOUSE-SELECT-DOWN</td>
<td>Press the mouse SELECT button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-SELECT-UP</td>
<td>Release the pressed mouse SELECT button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-SELECT-CLICK</td>
<td>Press and release the mouse SELECT button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-SELECT-DBLCLICK</td>
<td>Press and release the mouse SELECT button twice.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-MENU-DOWN</td>
<td>Press the mouse MENU button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-MENU-UP</td>
<td>Release the pressed mouse MENU button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-MENU-CLICK</td>
<td>Press and release the mouse MENU button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-MENU-DBLCLICK</td>
<td>Press and release the mouse MENU button twice.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-EXTEND-DOWN</td>
<td>Press the mouse EXTEND button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-EXTEND-UP</td>
<td>Release the pressed mouse EXTEND button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MOUSE-EXTEND-CLICK</td>
<td>Press and release the mouse EXTEND button.</td>

<tr>
<td>MIDDLE-MOUSE-CLICK</td>
<td>Press and release the middle mouse button.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>MIDDLE-MOUSE-DBLCLICK</td>
<td>Press and release the middle mouse button twice.</td>
<td>All</td>
<td>Trigger dependent</td>
</tr>
</tbody>
</table>

High-level widget events

Table 117 lists high-level widget events. These are events generated by mouse or keyboard actions that perform high-level operations on a widget, such as entering a fill-in, choosing a button, or displaying a menu. Unless noted in the AVM Action column, triggers on these events execute before the AVM applies the event. If the trigger returns NO-APPLY, the AVM does not apply the event. If the trigger executes after the event takes place, NO-APPLY has no effect.

Note: If a CHOOSE, DEFAULT-ACTION, or VALUE-CHANGED event executes a trigger as a result of a mouse click that changes input focus, NO-APPLY will return focus to the widget that had focus prior to the event.
Table 117: High-level widget events

<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHOOSE</td>
<td>A keyboard or mouse action that chooses a widget.</td>
<td>Button, non-toggle-box menu item</td>
<td>Trigger executes after choose takes place</td>
</tr>
<tr>
<td>DEFAULT-ACTION</td>
<td>A native keyboard or mouse event that confirms the selection of a value in a selection list or browse. In Windows applications, double-click a list item. In character applications, press RETURN or DELETE-LINE.</td>
<td>Selection list, Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>END</td>
<td>Occurs when the user repositions the browse to the end of the query’s result set by pressing the END key.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>END-SEARCH 1</td>
<td>Occurs when an updateable browse ends a user-initiated search when a user either selects a row marker or clicks in a cell.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
</tbody>
</table>
### Table 117: High-level widget events

<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>

</thead>
<tbody>
<tr>
<td>ENTRY</td>
<td>A keyboard or mouse action that gives focus to the widget.</td>
<td>Browse, browse cell, button, combo box, control container, dialog box, editor, fill-in, frame, radio set, selection list, slider, toggle box, window</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>Note: For a browse widget, <strong>ON ENTRY OF browse-name</strong> specifies a trigger for the browse widget and <strong>ON ENTRY OF column-name IN BROWSE browse-name</strong> specifies a trigger for a browse cell. The browse cell is the intersection of the named column and the currently focused row.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HOME</td>
<td>Occurs when the user repositions the browse to the beginning of the query’s result set by pressing the <strong>HOME</strong> key.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>ITERATION-CHANGED</td>
<td>A keyboard or mouse action that changes the current iteration of a browse. This event is obsolete; see the <strong>VALUE-CHANGED</strong> Event reference entry.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>LEAVE</td>
<td>A keyboard or mouse action that takes focus from the widget.</td>
<td>Browse, browse cell, button, combo box, control container, dialog box, editor, fill-in, frame, radio set, selection list, slider, toggle box, window</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>Note: For a browse widget, <strong>ON LEAVE OF browse-name</strong> specifies a trigger for the browse widget and <strong>ON LEAVE OF column-name IN BROWSE browse-name</strong> specifies a trigger for a browse cell. The browse cell is the intersection of the named column and the currently focused row.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>MENU-DROP</td>
<td>A keyboard or mouse action that displays a menu.</td>
<td>Menu,³ submenu</td>
<td>Trigger dependent</td>
</tr>
</tbody>
</table>
### Table 117: High-level widget events

<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF-END</td>
<td>A keyboard or mouse action that tries to move after the last row of a browse.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>OFF-HOME</td>
<td>A keyboard or mouse action that tries to move before the first row of a browse.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>PARENT-WINDOW-CLOSE</td>
<td>An event that each descendant window receives when the common ancestor window in that family receives a WINDOW-CLOSE event.</td>
<td>Window</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>ROW-DISPLAY</td>
<td>Any browse action that results in a row being displayed in the browse.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
</tbody>
</table>

**Note:** The use of triggers for this event is restricted to special cases. When a row is displayed, use a trigger to modify attributes of individual cells in the column. It should be restricted to the following uses: changing cell colors, changing the cell font, referencing the cell in an expression, and (in Windows) changing the cell format.
<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCROLL-NOTIFY</td>
<td>A mouse action in the scrollbar area of a browse.</td>
<td>Browse</td>
<td>Trigger dependent&lt;br&gt;&lt;br&gt;&lt;strong&gt;Note:&lt;/strong&gt; This event allows the&lt;br&gt;developer to track&lt;br&gt;physical movement&lt;br&gt;of the focused row&lt;br&gt;in the browse&lt;br&gt;viewport.</td>
</tr>
<tr>
<td>START-SEARCH¹</td>
<td>A keyboard or mouse action that places an updateable browse into search mode.</td>
<td>Browse</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>VALUE-CHANGED</td>
<td>A keyboard or mouse action that changes the value of a widget. For the&lt;br&gt;browse, any action that selects a row.</td>
<td>Browse, combo-box, editor (Windows GUI only), fill-in, radio set, selection list, slider, toggle box, toggle box menu item</td>
<td>Trigger executes&lt;br&gt;after value changes</td>
</tr>
<tr>
<td>WINDOW-CLOSE</td>
<td>A keyboard or mouse action that causes the native window manager to close the&lt;br&gt;affected window or dialog box.</td>
<td>Dialog box, window</td>
<td>Trigger dependent</td>
</tr>
<tr>
<td>WINDOW-MAXIMIZED¹</td>
<td>A keyboard or mouse action that causes the native window system to resize the window to its maximum size.</td>
<td>Window</td>
<td>Trigger executes after event takes place. However since the native system has control, a NO-APPLY does not stop the event from occurring.&lt;br&gt;&lt;br&gt;&lt;strong&gt;Note:&lt;/strong&gt; This event occurs only in Windows.</td>
</tr>
<tr>
<td>WINDOW-MINIMIZED</td>
<td>A keyboard or mouse action that causes the native window system to minimize (iconify) a window and hide all of its descendant windows.</td>
<td>Window</td>
<td>Trigger executes after event takes place. However, since the native system has control, a NO-APPLY does not stop the event from occurring.</td>
</tr>
</tbody>
</table>
Direct manipulation events

Direct manipulation events are ABL events that directly modify the size, shape, position, and appearance of a widget. These events are generated by mouse actions. Each user interface widget either has direct manipulation enabled or does not. Some types of widgets, such as menus, cannot have direct manipulation enabled. You can enable widgets for direct manipulation by setting the SELECTABLE, MOVABLE, or RESIZABLE attribute to TRUE.

If a widget has direct manipulation enabled, then direct manipulation events take priority over all other events. In other words, while data manipulation is enabled, the widget cannot perform data entry or application control functions. For example, if you set SELECTABLE to TRUE for a button, ABL interprets a MOUSE-SELECT-UP event as a SELECTION event. If you set SELECTABLE to FALSE, ABL interprets the same event as a CHOOSE event.

Direct manipulation events can be broken down into two types: general and frame-only. General direct manipulation events apply to both field-level and frame widgets. Frame-only direct manipulation events apply only to frames.

The following sections list the ABL events associated with direct widget manipulation. The user actions listed for these events assume that you set the appropriate attributes to make each event possible. For example, a widget must be SELECTABLE to receive the SELECTION event.

General direct manipulation events

Table 118 lists the direct manipulation events that apply to field-level widgets and frames.
<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESELECTION</td>
<td>For all selected widgets in a frame, click the mouse SELECT button on an unselected widget or in empty space in the frame. For a single selected widget, click the mouse EXTEND button on a selected widget.</td>
<td>Frame and field-level widgets with SELECTABLE attribute set to TRUE; browses. Internal: Sets the widget’s SELECTED attribute to FALSE. This setting takes effect after any trigger for the event executes. Screen: Removes the highlight from the affected widget or widgets.</td>
<td></td>
</tr>
<tr>
<td>END-MOVE</td>
<td>Release the pressed mouse MOVE button after moving the drag box for the widget or widgets.</td>
<td>Frame and field-level widgets with MOVABLE attribute set to TRUE; Also browse-columns. Internal: Generates an END-MOVE event for each moved widget. Screen: Moves each widget to the new x and y coordinates of its drag box.</td>
<td></td>
</tr>
<tr>
<td>END-RESIZE</td>
<td>Release the pressed mouse SELECT button after stretching the resize box to resize the widget.</td>
<td>Frame and field-level widgets with RESIZABLE and SELECTABLE attributes set to TRUE; Also browse-columns. Internal: Generates an END-RESIZE event for the resized widget. Screen: Resizes the widget to the new x and y coordinates of its resize box.</td>
<td></td>
</tr>
<tr>
<td>SELECTION</td>
<td>For a single unselected widget, click the mouse SELECT or EXTEND button on the widget. For multiple unselected widgets, release the pressed EXTEND button after drawing a select box around the widgets.</td>
<td>Frame and field-level widgets with SELECTABLE attribute set to TRUE. Internal: Sets each widget’s SELECTED attribute to TRUE. This setting takes effect after any trigger for the event executes. Screen: Highlights the affected widget or widgets.</td>
<td></td>
</tr>
</tbody>
</table>
### Table 118: General direct manipulation events

<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>START–MOVE</td>
<td>For a single widget, with the mouse pointer on the widget, press and hold the mouse MOVE button, and begin moving the mouse pointer. For multiple selected widgets—With the mouse pointer on any one of the selected widgets, press and hold the mouse MOVE button, and begin moving the mouse pointer.</td>
<td>Frame and field-level widgets with MOVABLE attribute set to TRUE; for multiple widgets, SELECTABLE attribute also set to TRUE; Also browse-columns.</td>
<td><strong>Internal</strong>: Sends a START–MOVE event to all selected widgets. If the trigger returns a NO-APPLY, the AVM does not generate the subsequent END–MOVE event. <strong>Screen</strong>: Draws a drag box around each of the one or more affected widgets, and moves each drag box in the direction of the moving mouse pointer.</td>
</tr>
<tr>
<td>START–RESIZE</td>
<td>With the mouse pointer on a resize handle of a selected widget, press and hold the mouse SELECT button and begin moving the mouse pointer.</td>
<td>Frame and field-level widgets with RESIZABLE and SELECTABLE attributes set to TRUE; Browse columns.</td>
<td><strong>Internal</strong>: Sends a START–RESIZE event to the selected widget. If the trigger returns NO-APPLY, the AVM does not generate the subsequent END–RESIZE event. <strong>Screen</strong>: Stretches a resize box around the widget in the direction of the moving mouse pointer.</td>
</tr>
<tr>
<td>START–ROW–RESIZE</td>
<td>With the mouse pointer on a row, press and hold the mouse SELECT button and begin moving the mouse pointer.</td>
<td>Browses.</td>
<td><strong>Internal</strong>: Sends a START–ROW–RESIZE event to the browse. If the trigger returns NO-APPLY, the AVM does not generate the subsequent END–ROW–RESIZE event. <strong>Screen</strong>: Stretches a resize box around the row in the direction of the moving mouse pointer.</td>
</tr>
</tbody>
</table>

### Frame-only direct manipulation events

Table 119 lists the direct manipulation events that apply only to frames.
<table>
<thead>
<tr>
<th>Event</th>
<th>User action</th>
<th>Affected widgets</th>
<th>AVM action</th>
</tr>
</thead>
</table>
| EMPTY-SELECTION      | Click the mouse SELECT button on an empty space in the frame.                | Frame and dialog box, whether its SELECTABLE attribute is set to TRUE or FALSE.   | **Internal:** Sends a DESELECTION event to all selected widgets in the frame and sends the EMPTY-SELECTION event to the frame.  
**Screen:** Removes the highlight around any selected widgets in the frame. |
| END-BOX-SELECTION    | Release the pressed mouse SELECT or EXTEND button after moving the mouse pointer to stretch the select box. | Frame and dialog box with BOX-SELECTABLE attribute set to TRUE.                  | **Internal:** If the user pressed the mouse SELECT button, the AVM sends a SELECTION event to all widgets surrounded by the select box. If the user pressed a mouse EXTEND button, the AVM sends a SELECTION event to all unselected widgets, and a DESELECTION event to all selected widgets surrounded by the select box.  
If a trigger on END-BOX-SELECTION returns NO-APPLY, the AVM does not send a subsequent SELECTION or DESELECTION event. Note that this behavior differs from the behavior of END-MOVE and END-RESIZE.  
**Screen:** Erases the select box, highlights selected widgets, and removes the highlight from deselected widgets. |
| START-BOX-SELECTION  | Press and hold the mouse SELECT or EXTEND button in an empty area of the frame and begin moving the mouse pointer. | Frame and dialog box with BOX-SELECTABLE attribute set to TRUE.                  | **Internal:** Sends a START-BOX-SELECTION event to the frame. If a trigger returns NO-APPLY, the AVM does not generate the subsequent END-BOX-SELECTION event.  
**Screen:** Draws a select box, which initially appears as a dot. |

**Table 119:** Frame-only direct manipulation events
Developer events

ABL provides eleven events, labeled U1 through U10 and CLOSE, that you can invoke on any widget using the APPLY statement. The only function of a developer event is the one provided by your own trigger definition.

Socket events

ABL looks for events to execute in the context of U/I blocking statements. During this processing if the AVM detects that data is available on a socket or that the remote end closed its socket or it detects that a client has connected to a port that the server has enabled connections to, a socket event is generated.

There are only two socket events, the READ-RESPONSE event, which applies only to socket objects, and the CONNECT event which applies only to server socket objects.

READ-RESPONSE event

AVM Detects — Data is available on a socket or the remote end of a connection has closed its socket; applies only to socket objects.

AVM Action — The AVM invokes the READ-RESPONSE event procedure.

The SET-READ-RESPONSE-PROCEDURE( ) method is used to name the READ-RESPONSE event procedure and to associate it with a socket object. The AVM invokes this procedure whenever it detects that data is available on the socket or that the remote end of the socket has closed its end of the socket. In this procedure, the SELF handle identifies the affected socket object.

To determine if the event procedure was invoked because data is available for reading or because of a disconnect, the application can use one of several methods:

- The CONNECTED( ) method returns FALSE if the socket is not connected to a port, TRUE if it is connected.
- The GET-BYTES-AVAILABLE( ) method returns zero if the socket is not connected to a port or the number of bytes available for reading if it is connected.
- The READ( ) method returns FALSE if the socket is not connected to a port. It returns TRUE and the read data if it is connected.

CONNECT event

AVM Detects — A client has connected to a port that the server has enabled connections to; applies only to server socket objects.

AVM Action — The AVM invokes the CONNECT event procedure.

The SET-CONNECT-PROCEDURE( ) method is used to name the CONNECT event procedure and to associate it with a server socket object. The CONNECT event procedure must accept one input parameter of type HANDLE. This is the handle to the implicitly created socket object for this connection. It is via this socket object that the server communicates with the client.
If the SET-CONNECT-PROCEDURE( ) method is not invoked, or if it fails, no connection procedure will be executed when the CONNECT event occurs.

**ProDataSet events**

ABL provides events you can invoke to execute application-specific code that handles FILL operations on a ProDataSet object or Buffer object, as well as row-level change operations. You can use the SET-CALLBACK-PROCEDURE( ) method to associate an action with these events.

Event procedures must define a single parameter for the ProDataSet object (DATASET or DATASET-HANDLE) as an INPUT parameter BY-REFERENCE. This allows the event procedure to operate on the ProDataSet object using static ABL to reference its buffers and fields, without the ProDataSet object being physically copied. This also means that because the ProDataSet object is not copied, changes made to the ProDataSet object by the event procedure are made to the same copy used by all procedures.

The following sections describe the ProDataSet events:

- **FILL events**
- **Row-level events**
- **OFF-END event**
- **FIND-FAILED event**
- **SYNCHRONIZE event**

**FILL events**

There are two levels of FILL events: the first level is for a ProDataSet object or one of its member buffer objects; the second level is for individual records created in each temp-table.

Table 120 lists the first-level FILL events.
### Table 120: First-level FILL events

<table>
<thead>
<tr>
<th>Event</th>
<th>Affected objects</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFTER-FILL</td>
<td>Buffer object of a DATASET temp-table, ProDataSet object</td>
<td>This event occurs at the very end of a FILL, and can be used to adjust the contents of the ProDataSet object or Buffer object, reject the FILL operation, or disconnect from a server or database. For a child table, the event occurs once for each parent record that is created.</td>
</tr>
<tr>
<td>BEFORE-FILL</td>
<td>Buffer object of a DATASET temp-table, ProDataSet object</td>
<td>This event occurs at the very beginning of a FILL, before anything is read or created.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For a Buffer object, this event allows the developer to do preparatory work for an individual table. For the parent table in a set of related tables, where the FILL event is applied to this top-level table, it could be the same kind of connection code as for the ProDataSet object as a whole. For a child table, the event occurs once for each parent record that is created, and allows the developer to adjust the query for the child table, or cancel the FILL for that parent altogether. For a ProDataSet object, this event allows the developer to make a server or database connection, or do other preparatory work. Alternatively, it allows the developer to intercept and fully replace the default behavior.</td>
</tr>
</tbody>
</table>

Table 121 lists the second-level FILL events. These events occur once immediately before or after each record is created in a temp-table during a FILL.

### Table 121: Second-level FILL events

<table>
<thead>
<tr>
<th>Event</th>
<th>Affected objects</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFTER-ROW-FILL</td>
<td>Buffer object of a DATASET temp-table</td>
<td>This event occurs after a record is created in the temp-table. The procedure can, for example, modify field values in the record by supplying values for calculated fields, or perform filtering and reject a record by deleting it. The procedure cannot modify record currency using the ProDataSet object buffers in any other way. It can use separately defined buffers to modify the ProDataSet object in other ways. The procedure can RETURN ERROR to abort the entire FILL, or RETURN NO-APPLY to cancel the cascading of the FILL to child buffers, if any.</td>
</tr>
<tr>
<td>BEFORE-ROW-FILL</td>
<td>Buffer object of a DATASET temp-table</td>
<td>This event occurs before a record is created in the temp-table, but after the data source record(s) for it are read. For example, this procedure could examine the database buffers or other information and decide not to create the record, using a RETURN NO-APPLY statement.</td>
</tr>
</tbody>
</table>

1847
Row-level events

Row-level events are defined for making local changes to the records in a ProDataSet member buffer object. Table 122 lists the row-level events.

Table 122: Row-level events

<table>
<thead>
<tr>
<th>Event</th>
<th>Affected objects</th>
<th>AVM action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW-CREATE</td>
<td>Buffer object of a DATASET temp-table</td>
<td>This event occurs immediately after the record is created in the temp-table. The current buffer for the temp-table is available and contains initial values as defined in the temp-table definition (or inherited from the schema). You can use this event to calculate initial values for fields, make changes to other records, or reject the creation by deleting the new temp-table record.</td>
</tr>
<tr>
<td>ROW-DELETE</td>
<td>Buffer object of a DATASET temp-table</td>
<td>This event occurs when you delete a temp-table record, immediately before the record is deleted. The event procedure can use this event to RETURN ERROR to cancel the delete, or to make adjustments to other records based on the delete. Since the record has not yet been deleted, the record is in the temp-table buffer and the code can look at its values. Because the code can assume that the DELETE will go through unless cancelled by the event procedure itself, it can take actions based on the record deletion while the record is still there to be looked at.</td>
</tr>
</tbody>
</table>
| ROW-UPDATE| Buffer object of a DATASET temp-table | This event occurs immediately before the record is updated in the temp-table. It typically occurs when:  
  - The buffer scope ends  
  - The transaction scope ends  
  - The RELEASE statement or BUFFER-RELEASE( ) method is run on the buffer  
  - The buffer is needed for another record  
  
  The AVM sets the SELF system handle to the handle of the buffer on which the event procedure is running before calling the event handler. If the event handler returns NO-APPLY or ERROR, the return is ignored. The handler has run, and it is too late to undo any changes to the record.  
  
  You can use this event to determine if and how a record has changed by reading the buffer in the before-image table (using the SELF:BEFORE-ROWID attribute) and comparing it to the updated buffer. You can also use this event in the event handler to update fields in the record (for example, to supply a calculated field).  
  
  You cannot read another record into the buffer on which the event procedure is running in the event handler. If you need to read another record, use a different buffer to avoid disturbing the record you are currently updating. |
OFF-END event

The OFF-END event occurs when you position a query on a ProDataSet temp-table buffer past the last row. You can use this event to retrieve additional data source rows to add at the bottom of a ProDataSet temp-table (for example, in batches when there are too many data source rows to retrieve at one time).

The OFF-END event can also occur when the user performs a keyboard or mouse action in a browse that scrolls off the end (past the last row) of a browse on a ProDataSet temp-table buffer. For more information about using the OFF-END event with a browse, see the “High-level widget events” section on page 1836.

Note: The OFF-END event is similar to the QUERY-OFF-END attribute, which is set to TRUE whenever the associated query object is positioned past the last row. The difference is that you must test the QUERY-OFF-END attribute for this condition at a specific place in your application code, whereas the OFF-END event procedure executes like a trigger whenever the event occurs.

Consider the following restrictions when using the OFF-END event with a query on a ProDataSet temp-table buffer:

- You can attach these events only to a query on a single ProDataSet temp-table buffer. You cannot attach these events to a query on a database buffer, or a query that involves a join.
- The query must be a scrolling query.
- If you never RETURN NO-APPLY, from the OFF-END event handler, the query will infinitely loop.
- Call the SET-CALLBACK-PROCEDURE( ) method before the query is opened.
- If you use the GET LAST statement or GET-LAST( ) method to get the last record associated with the query, the event handler is called repeatedly until it does not RETURN NO-APPLY (indicating that all records have been retrieved). For this reason, use caution when offering users the GET LAST action.
- The INDEXED-REPOSITION option is ignored for the query.

FIND-FAILED event

The FIND-FAILED event occurs when a FIND on a ProDataSet temp-table buffer fails. This can be the result of the FIND statement (but not the FIND NEXT, FIND PREV, or FIND LAST statements, and not the CAN-FIND function), or the FIND-FIRST( ) or FIND-UNIQUE( ) methods (but not on the FIND-LAST( ) method).

You can use this event to adjust the contents of the ProDataSet object. The event handler must be able to determine the action to take based on the context of the ProDataSet object, and must RETURN NO-APPLY to indicate the action was successful. For example, when the event occurs, the event handler could retrieve a missing row or a set of related rows from the server automatically.
SYNCHRONIZE event

The SYNCHRONIZE event occurs when a ProDataSet temp-table buffer is synchronized. That is, when the SYNCHRONIZE() method is run on the buffer or a parent buffer, or the buffer is selected in a browse. The event handler is invoked recursively at every level of the ProDataSet object hierarchy just before the recursion to the child levels.

By default, if the query is associated with a browse, the synchronize action of reopening the query automatically refreshes the browse. If the query is not associated with a browse, the synchronize action automatically gets the first row in the query by invoking a GET FIRST operation. If there is a REPOSITION data relation and no browse, the synchronize action gets the next record in the query by invoking a GET NEXT operation. Once these actions attempt to populate the buffer at a particular level, the SYNCHRONIZE event runs before moving recursively to the next lower level.

This event allows you to fetch rows, display buffer values in a frame, or take some other action. The handler procedure can also RETURN NO-APPLY to cancel the cascading of the synchronization to child buffers.
This section contains reference entries that describe the built-in classes and interfaces supported in ABL, including both native ABL classes and interfaces and OpenEdge .NET classes and interfaces. For information on working with ABL classes and interfaces, see *OpenEdge Development: Object-oriented Programming*. For information on working with .NET classes and interfaces, see *OpenEdge Development: GUI for .NET Programming*.

The built-in ABL classes and interfaces support access to user-defined ABL classes and interfaces and also provide the foundation for structured error handling in ABL. They also support features of the ABL model for accessing .NET objects, including the handling of .NET exceptions using ABL structured error handling. For information on the properties and methods of these built-in ABL classes and interfaces, see the “Class Properties and Methods Reference” section on page 1889.

The built-in OpenEdge .NET classes and interfaces support ABL access to .NET objects. Some of the OpenEdge .NET classes extend Microsoft .NET classes. The reference entries for these classes list the OpenEdge built-in and extended properties, methods, and events that allow you to monitor and control the behavior of these class-based objects. For more information on the properties and methods listed for each OpenEdge .NET class and interface, see the “Class Properties and Methods Reference” section on page 1889. For more information on the .NET events listed for each OpenEdge .NET class, see the “Class Events Reference” section on page 1953 in this manual. For information on the Microsoft .NET properties, methods, and events not listed in this manual for an extended Microsoft .NET class, see the .NET Framework class library.

ABL views all .NET classes and interfaces as ABL object types by treating the .NET root class, System.Object, as an immediate subclass of the ABL root class, Progress.Lang.Object. In this way, ABL merges the .NET type system with the ABL object type system, making the .NET type system act from within ABL as an extension of Progress.Lang.Object. However, .NET does not have any knowledge of the ABL type system. That is, ABL extends its own type system with .NET, but .NET does not recognize object types defined in ABL. For more information on ABL support for .NET types, see the Data types reference entry.
In addition to the OpenEdge .NET classes specifically referenced in this book, OpenEdge provides a set of third party .NET controls (OpenEdge Advanced UI Controls) for use with .NET forms and control containers. These Advanced UI Controls are supported for access as visual design objects in the Visual Designer of OpenEdge Architect. For more information, see the appendix that lists these controls in *OpenEdge Development: GUI for .NET Programming*.

The following descriptions refer to both compile-time and run-time behavior, features that the language generally supports and determines at compile time and actions directed by using these features at run time. When describing ABL compile-time features or actions, ABL or the ABL compiler is the actor. When describing ABL or .NET actions taken at run time, the AVM (ABL Virtual Machine) or .NET (respectively) is the actor.

**Progress.Data.BindingSource class**  
(Windows only; GUI for .NET only)

A BindingSource object (the ProBindingSource) that allows you to bind a .NET control on a form to one of the following ABL data source objects:

- A query involving a temp-table or database table (which can be a join query)
- A ProDataSet object
- A Buffer object

**Note:** Progress Software Corporation recommends that you open (or reopen) any query associated with a ProBindingSource instance using the PRESELECT option, which optimizes query performance.

The Progress.Data.BindingSource class is an OpenEdge .NET class that extends the .NET System.Windows.Forms.BindingSource class. The ProBindingSource acts as a conduit between a .NET control and an ABL data source object. A bound .NET control considers the ProBindingSource to be its data source. In turn, the ProBindingSource sets the underlaying ABL data source object as its data source. For a complete overview of data binding between .NET controls and ABL data source objects, see *OpenEdge Development: GUI for .NET Programming*. 
Constructors

PUBLIC BindingSource ( INPUT query-hdl AS HANDLE
                          [ , INPUT include-fields AS CHARACTER,
                            INPUT except-fields AS CHARACTER ] )

PUBLIC BindingSource ( INPUT dataset-hdl AS HANDLE
                          [ , { INPUT parent-buffer-name AS CHARACTER
                                   | INPUT parent-buffer-hdl AS HANDLE } ]
                          [ , INPUT include-fields AS CHARACTER,
                            INPUT except-fields AS CHARACTER ] )

PUBLIC BindingSource ( INPUT buffer-hdl AS HANDLE
                          [ , INPUT include-fields AS CHARACTER,
                            INPUT except-fields AS CHARACTER ] )

PUBLIC BindingSource ( )

query-hdl

A HANDLE variable that represents the handle to a query object.

dataset-hdl

A HANDLE variable that represents the handle to a ProDataSet object.

buffer-hdl

A HANDLE variable that represents the handle to a buffer object.

parent-buffer-name

A CHARACTER variable that represents the name of a parent buffer in a ProDataSet object. This corresponds to the top-level table displayed in a hierarchical control (such as a grid or a treeview).

parent-buffer-hdl

A HANDLE variable that represents the handle to a parent buffer in a ProDataSet object. This corresponds to the top-level table displayed in a hierarchical control (such as a grid or a treeview).

include-fields

An optional CHARACTER expression that evaluates to a comma-separated list of fields in the ABL data source object to bind to the ProBindingSource. To include all fields, specify an asterisk ("*"), in include-fields. To include all but a few fields, specify an asterisk ("*"), in include-fields and a comma-separated list of fields to exclude in except-fields. If include-fields contains specific fields, except-fields is ignored.

When including fields for a ProDataSet object, you must specify a comma-separated list of fields to display in display order and qualify the field names with their buffer name. For example:

"table1.field1, table1.field2, table2.field1, table1.field3"
You must specify at least one field from each table in the hierarchy to be displayed.

When including fields for a query or a join query, you must specify a comma-separated list of fields to display in display order and you should qualify ambiguous field names with their buffer name.

Do not specify a RAW temp-table or a database field in `include-fields`. If you explicitly specify a RAW field, the AVM generates a run-time error. If you specify an asterisk ("*"") to include all fields and there is a RAW field in the table, the AVM excludes it automatically even if it is not specified in `except-fields`.

`except-fields`

A CHARACTER expression that evaluates to a comma-separated list of fields in the ABL data source object to exclude from binding to the ProBindingSource. You can specify fields to exclude only when `include-fields` contains an asterisk ("*"). If you do not have any fields to exclude, you must specify the empty string ("""). If `include-fields` contains specific fields, `except-fields` is ignored.

**Binding to a query associated with a temp-table or database table**

When binding to a temp-table or database table through a query, consider the following:

- The query may, or may not, be part of a ProDataSet object.
- The query can be either static or dynamic.
- You use a handle to access either a static or a dynamic query.
- The query must be scrolling. That is, a static query must be defined with the SCROLLING keyword and a dynamic query, which defaults to scrolling, must remain that way (its FORWARD-ONLY attribute must be FALSE).
- The query can be a join involving one or more tables. In this case, one row is displayed in the control for each result list entry.
- The ProBindingSource takes information from the table schema definition and makes it available to the bound .NET control for headings and labels. The ProBindingSource determines headings and labels by using either the column label (if defined), the field label (if defined), or the field name from the schema.

If the query is a join with duplicate field names in the tables, you should qualify the field names with the buffer names using the `buffer-name.field-name` syntax. Also, the ProBindingSource treats elements in an array field as separate fields and makes them unique by appending their array subscript using the `array-name[subscript]` syntax.

- If the .NET control does not handle sorting on its own, you can do either of the following:
  - Let the ProBindingSource automatically sort records in the ABL data source object by setting the AutoSort property to TRUE.
  - Define a trigger to handle a SortRequest event.

**Note:** If you need to reopen the query, you must do so using the QUERY-PREPARE and QUERY-OPEN methods (not the OPEN QUERY method).
Progress.Data.BindingSource class

statement). Progress Software Corporation recommends that you reopen the query using the PRESELECT option, which optimizes query performance.

- The ProBindingSource automatically changes currency in the query (as reflected by the Position property) as the selected row in the bound .NET control changes.

**Binding to a ProDataSet object**

Binding to a ProDataSet object enables you to create a hierarchical display of a parent buffer and its child buffers in the same .NET control (such as a grid or a treeview). When binding to a ProDataSet object, consider the following:

- The ProDataSet object can contain one or more parent and child buffers (and a set of data relations describing the relationship between the parent and child buffers).
- The ProDataSet object can be either static or dynamic.
- You use a handle to access either a static or dynamic ProDataSet object.
- You can identify a temp-table in a ProDataSet object by either its name or its handle.
- To bind a hierarchy of parent and child buffers to a single .NET control, specify a parent buffer from the ProDataSet object as the top-level table to display in the .NET control. A parent buffer is typically a top-level buffer in the ProDataSet object, but it need not be. Any child buffers of the specified parent buffer are automatically included in the hierarchy. The ProBindingSource makes a buffer’s data available to a bound .NET control as follows:
  - If you specify a parent buffer that is a top-level buffer, the ProBindingSource uses the buffer’s top-level navigation query (specified by the TOP-NAV-QUERY attribute) to populate the primary set of records, and uses the data-relation queries associated with each of the child buffers for subsequent levels.
  - If you specify a parent buffer that is not a top-level buffer, the ProBindingSource uses the buffer’s data-relation query to populate the primary set of records, and uses the data-relation queries associated with each of the child buffers for subsequent levels.
  - If you specify a buffer that is not a parent buffer (that is, a buffer that has no child buffers), the ProBindingSource binds to a single table. You can achieve this same result by binding to the buffer’s top-level navigation query (specified by the TOP-NAV-QUERY attribute) or its data-relation query.
  - If you do not specify any buffer, the ProBindingSource binds to the first top-level buffer in the ProDataSet object. The first top-level buffer is based on the order in which the buffers were defined or added in the ProDataSet object, and it matches the result from GET-TOP-BUFFER(1).
- To display both parent and child buffers within the same .NET control, use a single ProBindingSource instance bound to the ProDataSet object. To display the parent and child buffers in separate .NET controls, use separate ProBindingSource instances bound to their respective queries.
The ProBindingSource automatically changes currency in the parent buffer (as reflected by the Position property) as the selected parent or child row in the bound .NET control changes.

For more information on how the ProBindingSource manages currency between parent and child buffers, including a code example, see the data-binding chapter in *OpenEdge Development: GUI for .NET Programming*.

When the user first expands (not selects) a parent row in the bound .NET control, all of the child rows for that parent row are displayed. The ProBindingSource uses the ProDataSet object’s data-relation query to create and maintain a unique query for all child rows related to the expanded parent row. For example, if the user expands multiple parent rows, there will be an open child query for each expanded parent row based on the corresponding parent record.

The ProBindingSource takes information from the ProDataSet object schema definition and makes it available to the bound .NET control for headings and labels. The ProBindingSource determines headings and labels by using either the column label (if defined), the field label (if defined), or the field name from the schema.

**Binding to a buffer object**

When binding to a temp-table or database buffer, consider the following:

- The buffer might (but not necessarily) be part of a ProDataSet object.
- The buffer can be either static or dynamic.
- You use a handle to access either a static or dynamic buffer.
- Use a buffer as a data source for one or more single-value controls (such as a check box or a text box).
- The Position property value will always be set to zero. Therefore, you must manage currency for the buffer by changing the record in the ABL data source object programatically.

**Binding to an unbound ProBindingSource instance**

An unbound ProBindingSource instance is created by invoking the ProBindingSource constructor with no parameters. When binding to an unbound ProBindingSource instance, consider the following:

- To limit which fields are exposed in the data source object, use the SetFields( ) method before binding to the data source object.
- You must bind an unbound ProBindingSource object instance to an ABL data source object at run time by setting the ProBindingSource’s Handle property to the handle of the associated ABL data source object.
- When you set the ProBindingSource’s Handle property, the AVM includes, by default, all fields from the ABL data source object’s schema in the .NET control. (This is equivalent to specifying an asterisk (“*”) in the *include-fields* parameter when invoking a ProBindingSource constructor with parameters.) If you want to limit the available fields, you must use the ProBindingSource’s SetFields( ) method before you specify the Handle.
property. Attempting to use the SetFields() method after specifying the Handle property causes the ProBindingSource to throw a .NET exception.

Super Class
System.Windows.Forms.BindingSource class (from the .NET Framework)

Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

Notes

• Since you are working with a combination of .NET controls and ABL objects, it is important to remember that .NET control parameter and property indexes are always zero-based values and ABL indexes are always one-based values.

• For information on the public class members inherited from the System.Windows.Forms.BindingSource class, refer to the .NET Framework class library.

Progress.Data.CancelCreateRowEventArgs class (Windows only; GUI for .NET only)

A CancelCreateRowEventArgs object instance that is an argument to an event handler for a CancelCreateRow event.

Constructors
This class contains a private constructor; you cannot instantiate it directly.

Super Class
System.EventArgs class (from the .NET Framework)
Progress.Data.ColumnPropDesc class

**Interfaces**
This class does not implement interfaces (beyond those it inherits from its base class).

**Public Properties**

<table>
<thead>
<tr>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>BandIndex</td>
</tr>
<tr>
<td>BufferHdl</td>
</tr>
<tr>
<td>BufferName</td>
</tr>

**Public Events**
This class does not contain events (beyond those it inherits from its base class).

**Note**
For information on the public class members inherited from the System.EventArgs class, refer to the .NET Framework class library.

**See also** CancelCreateRow event, CreateRow event, CURRENT-QUERY( ) method, Progress.Data.CreateRowEventArgs class

---

**Progress.Data.ColumnPropDesc class**
(Windows only; GUI for .NET only)

A design-time object that the Visual Designer uses to describe a table column (field) as part of logical schema information that it associates with a Progress.Data.BindingSource class instance using the Progress.Data.TableDesc class.

**Note:** This class is designed for use by the Visual Designer. Though you can do so, it is not expected that you will use this in your own code.

**Constructor**

```plaintext
PUBLIC ColumnPropDesc ( INPUT col-name AS CHARACTER ,
                        INPUT col-label AS CHARACTER ,
                        INPUT col-type AS CLASS Progress.Data.DataType )
```

**col-name**
A CHARACTER expression that represents the name of the table column.

**col-label**
A CHARACTER expression that represents a label for the table column. If `col-label` is set to the Unknown value (?), the label for the field is determined at run time according to OpenEdge column label rules.

**Note:** A field label specified in a control always takes precedence over the field label supplied by the BindingSource.

**col-type**
A Progress.Data.DataType enumeration class value that describes the ABL data type of the column.
Progress.Data.CreateRowEventArgs class

(Windows only; GUI for .NET only)

A CreateRowEventArgs object instance that is an argument to an event handler for a CreateRow event.

Constructors

This class contains a private constructor; you cannot instantiate it directly.

Super Class

System.EventArgs class (from the .NET Framework)

Interfaces

This class does not implement interfaces (beyond those it inherits from its base class).

Super Class  System.Enum class (from the .NET Framework)

Note

- For information on the System.Enum class, refer to the .NET Framework class library.
- The ProBindingSource exposes an ABL BLOB field (a Binary Large Object) to any bound .NET control as a .NET System.Byte[] data type. Before binding a BLOB to a particular .NET control, check the .NET control’s user documentation to see if it can render the type of file that the BLOB represents.

For example, if you bind an image BLOB to a Microsoft DataGridView, the grid represents the BLOB as a Systems.Windows.Forms.DataGridViewImageColumn class. If the BLOB is not in a recognized format, the class throws an error. If you bind the same BLOB to an UltraGrid from the OpenEdge Advanced UI Controls, the grid represents the BLOB as an UltraGridColumn of the System.Byte[] data type. In order to display the image, you must then add an editor control to the column using something like the following code:
The ProBindingSource exposes an ABL CLOB field (a Character Large Object) to any bound .NET control as a .NET System.String data type. Be sure that the .NET control can handle that data type.

See also Progress.Data.ColumnPropDesc class

Progress.Data.InputValue class
(Windows only; GUI for .NET only)

Provides indexers you can use to access the input value of the specified field in the current row of a table displayed in the bound .NET control.

Note: Using an instance of this class is analogous to using the INPUT-VALUE attribute for a field value displayed in an ABL widget.

Constructors This class does not contain a constructor.

Super Class System.Object class (from the .NET Framework)

Interfaces This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties This class does not contain properties (beyond those it inherits from its base class).

**Public Events**
This class does not contain events (beyond those it inherits from its base class).
Progress.Data.TableDesc class
(Windows only; GUI for .NET only)

A design-time object that the Visual Designer uses to store logical schema information that you specify for the data source associated with a Progress.Data.BindingSource class instance. The specified logical schema can represent a single temp-table or a hierarchy of temp-tables in a ProDataSet, where the current instance describes the parent for a specified set of child tables.

**Note:** This class is designed for use by the Visual Designer. Though you can do so, it is not expected that you will use this in your own code.

**Constructor**

```csharp
PUBLIC TableDesc ( INPUT name AS CHARACTER,
                   INPUT columns AS CLASS "Progress.Data.ColumnPropDesc[]",
                   INPUT children AS CLASS "Progress.Data.TableDesc[]"
)
```

- **name**
  A CHARACTER expression that represents a table name for the logical schema.

- **columns**
  An array of Progress.Data.ColumnPropDesc class instances that describe the fields of the table represented by this TableDesc instance.

- **children**
  An array of Progress.Data.TableDesc class instances that describe child tables of the parent table represented by this instance. If this table has no child tables, children is set to the Unknown value (?).

**Super Class**  System.Object (from the .NET Framework)

**Interfaces**  System.Runtime.Serialization.ISerializable interface (from the .NET Framework).

**Public Properties**  The public properties defined by this class are not supported for use in applications.

**Public Methods**  The public methods defined by this class are not supported for use in applications.

**Public Events**  The public events defined by this class are not supported for use in applications.
Progress.Lang.AppError class

**Note**  For information on the public class members inherited from the System.Object class, refer to the .NET Framework class library.

**See also**  Progress.Data.BindingSource class, Progress.Data.ColumnPropDesc class, TableSchema property

---

**Progress.Lang.AppError class**

Progress.Lang.AppError is the ultimate super class of all application errors. An *application error* is simply any collection of data you need to provide meaningful information about a condition. Representing a user-defined error as an error object allows your application to throw and catch or return the error in the ABL structured error handling model.

**Note:** See the CATCH statement, UNDO statement, and RETURN statement for more information.

The following figure represents the hierarchy of ABL classes that provide Progress.Lang.AppError with all its features:

![Diagram of ABL class hierarchy]

Progress.Lang.ProError is the ultimate super class of all error objects in ABL. From Progress.Lang.Object it inherits the basic features of an ABL class. It also implements the Progress.Lang.Error interface which provides the basic properties and methods for handling errors.

Progress.Lang.AppError adds the properties and methods needed for populating an AppError object with your error messages.
You can create your own hierarchy of more complex AppError types by subclassing AppError.

When the AVM encounters the RETURN ERROR statement, it implicitly throws a Progress.Lang.AppError error object and places any error string in the object’s ReturnValue property.

**Constructors**
The following is the default constructor. This constructor creates an AppError object with an empty message list and does not set any properties.

**Syntax**

```
PUBLIC AppError()
```

The following constructor creates an AppError object and assigns the first message on the object with the values from the ErrorMessage and MessageNumber arguments. It also sets the NumMessages property to 1. This error message and message number can be accessed with the GetMessage(1) and GetMessageNum(1) methods.

**Syntax**

```
PUBLIC AppError( INPUT ErrorMessage AS CHARACTER
                   INPUT MessageNumber AS INTEGER )
```

The following constructor creates an AppError object with the ReturnValue property set with the value of the ErrorString parameter. This constructor is used when the AVM implicitly creates an AppError object for a RETURN ERROR ErrorString statement. You can also invoke this constructor directly.

**Syntax**

```
PUBLIC AppError( INPUT ReturnValue AS CHARACTER )
```

**Super Class**
Progress.Lang.ProError class

**Interfaces**
This class does not implement interfaces (beyond those it inherits from its base class).

**Public Properties**

| ReturnValue property | –                                      |

**Public Methods**

| AddMessage( ) method | RemoveMessage( ) method |

**Public Events**
This class does not contain events.

**Note**
All AppError instances, both those created implicitly and user-defined application errors, created with the NEW function (classes) appear on the SESSION-FIRST-OBJECT chain, just like any other user-defined object.

**See also**
Progress.Lang.SysError class
Progress.Lang.Class provides type information about an ABL class or an interface. ABL provides a Progress.Lang.Class instance for each ABL class or interface type in the ABL session.

Constructors
This class contains only a private constructor; you cannot instantiate it directly.

Super Class
Progress.Lang.Object class

Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties
<table>
<thead>
<tr>
<th>Package property</th>
<th>SuperClass property</th>
<th>TypeName property</th>
</tr>
</thead>
</table>

Public Methods
- GetClass( ) method (Progress.Lang.Class)
- HasStatics( ) method
- HasWidgetPool( ) method
- Invoke( ) method (Class)
- IsA( ) method
- IsAbstract( ) method
- IsFinal( ) method
- IsInterface( ) method
- New( ) method

Public Events
This class does not contain events.

Notes
- ABL does not support this class for use with .NET object types.
- To obtain the object reference for the Progress.Lang.Class instance associated with a given ABL class or interface, you must call the GetClass( ) method either as an instance method on an ABL class (any Progress.Lang.Object instance except a .NET type) or as a static method of Progress.Lang.Class using the following syntax:

  **Syntax**

  ```
  class-reference = object-reference:GetClass( ).
  ```

  Where `object-reference` is the object reference to an ABL class instance for which you want to get the type information, `expression` is a CHARACTER expression that specifies the fully-qualified ABL object type name whose type information you want to get, and `class-reference` is the object reference for the Progress.Lang.Class instance containing that type information. For example:

  ```
  DEFINE VARIABLE myCustObj AS Progress.Lang.Object NO-UNDO.
  DEFINE VARIABLE myType AS Progress.Lang.Class NO-UNDO.

  ASSIGN
  myType = Progress.Lang.Class:GetClass("acme.myObjs.CustObj")
  myCustObj = myType:New().
  ```
Progress.Lang.Error interface

The Progress.Lang.Error interface describes a common set of properties and methods that built-in ABL error classes implement to interact with the ABL structured error handling model. This interface cannot be implemented by a user-defined class. Instead, to create your own ABL error class, subclass the Progress.Lang.AppError class.

This interface is also implemented by an OpenEdge-enhanced version of the .NET System.Exception class (OpenEdge-enhanced). Because of this architecture, ABL recognizes .NET exceptions as error objects and ABL error handling features can recognize, handle, and re-throw .NET exceptions. The interface requires a class to implement the following properties:

<table>
<thead>
<tr>
<th>Public Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>CallStack property</td>
</tr>
</tbody>
</table>

The interface requires a class to implement the following methods:

<table>
<thead>
<tr>
<th>Public Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetMessage( ) method (Class)</td>
</tr>
</tbody>
</table>

Notes

The Progress.Lang.Error interface provides an abstract mechanism for integrating ABL and third-party error objects into the ABL structured error handling model. As such, it is the error type that represents all possible errors in ABL. Specifying this interface in a CATCH statement, creates an error handler that catches any error. For example:

```
DO ON ERROR UNDO, THROW:
   . . .
   CATCH anyErrorObject AS Progress.Lang.Error:
      . . .
   END CATCH.
END.
```

See also

Progress.Lang.Object class

Progress.Lang.Object provides a common set of properties and methods that all classes inherit. This set of properties and methods let you write common code to use with any user-defined class.

Progress.Lang.Object is the root (ultimate super) class for all ABL classes and for all .NET classes referenced in an ABL session.
Progress.Lang.ParameterList class

Constructors

PUBLIC Object( )

Super Class

This class does not inherit a super class.

Interfaces

This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties

NEXT-SIBLING property       PREV-SIBLING property

PUBLIC ParameterList ( INPUT number-parameters AS INTEGER )

Number of parameters that the object will contain.

Super Class

Progress.Lang.Object class

Interfaces

This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties

NumParameters property
Progress.Lang.ProError class

Progress.Lang.ProError is the ultimate super class for all ABL built-in and user-defined classes that represent errors in the ABL structured error handling model. You cannot directly inherit from this class. Instead, the immediate subclasses of this class represent the two major types of classes in ABL:

- Progress.Lang.SysError represents any error generated by the AVM.
- Progress.Lang.AppError represents any error your application defines.

Progress.Lang.ProError inherits from Progress.Lang.Object and therefore inherits all the common methods and properties needed for managing user-defined objects in ABL. It also implements the Progress.Lang.Error interface which provides all the properties and methods needed to interface with the ABL structured error handling model.

Specifically, this class provides the functionality to retrieve error messages, error numbers, and the contents of the error call stack.

Constructors

The class constructors are reserved for system use only.

Super Class

Progress.Lang.Object class

Interfaces

Progress.Lang.Error interface

Public Properties

<table>
<thead>
<tr>
<th>CallStack property</th>
<th>NumMessages property</th>
<th>Severity property</th>
</tr>
</thead>
</table>

Public Methods

<table>
<thead>
<tr>
<th>GetMessage( ) method (Class)</th>
<th>GetMessageNum( ) method</th>
</tr>
</thead>
</table>

Public Events

This class does not contain events.

Note

Like any other class-based object that is no longer referenced, the AVM automatically deletes both Progress.Lang.SysError objects and Progress.Lang.AppError objects using garbage collection.

See also

Progress.Lang.SoapFaultError class

Represents an ABL Soap fault response message generated by the AVM during a Web Service call from an ABL application. Progress.Lang.SoapFaultError inherits from Progress.Lang.SysError and is a FINAL class.

In traditional error handling, Soap fault information is available from the ERROR-OBJECT-DETAIL property of the ERROR-STATUS handle after a Web Service call is invoked with the NO-ERROR option.

In structured error handling, you can access the same information using a CATCH statement for the Progress.Lang.SoapFaultError object. The SoapFault property in this object contains the handle to the Soap-Fault object. The Soap-Fault-Detail property of the handle provides the full detail about the Soap fault.

SoapFaultError is a type of system error, and therefore you cannot instantiate the object with the NEW function (classes) or create a user-defined class that inherits from it.

Constructors
The class constructors are reserved for system use only.

Super Class
Progress.Lang.SysError class

Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties

<table>
<thead>
<tr>
<th>Public Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>SoapFault property</td>
</tr>
</tbody>
</table>

Public Methods
This class does not contain methods.

Public Events
This class does not contain events (beyond those it inherits from its base class).

Notes
- SoapFaultError objects are put on the SESSION:FIRST-OBJECT chain when they are caught by a CATCH block.
- Uncaught SoapFaultError objects are automatically deleted by the AVM and removed from the SESSION:FIRST-OBJECT chain.

See also
Progress.Lang.SysError class

---

Progress.Lang.SysError class

When an ABL statement raises the error condition, the AVM throws an error. These errors are represented by the Progress.Lang.SysError class. Progress.Lang.SysError inherits common error handling abilities from Progress.Lang.ProError.

You cannot inherit from this class.

Constructors
The class constructors are reserved for system use only.

Super Class
Progress.Lang.ProError class
Progress.Util.DateTimeHelper class

(Windows only; GUI for .NET only)

A helper class that provides a set of static Create( ) method overloads for initializing DATETIME values in ABL.

**Note:** This class is used primarily by the Visual Designer during code generation. You should not expect to use this class directly.

**Constructors**
This class does not contain a constructor.

**Super Class**
This class does not inherit a super class.

**Interfaces**
This class does not implement interfaces (beyond those it inherits from its base class).

**Public Properties**
This class does not contain properties (beyond those it inherits from its base class).

**Public Methods**

<table>
<thead>
<tr>
<th>Create( ) method (DATETIME)</th>
</tr>
</thead>
</table>

**Public Events**
This class does not contain events (beyond those it inherits from its base class).

**See also**
Progress.Util.DecimalHelper class, Progress.Util.StringHelper class
Progress.Util.DecimalHelper class
(Windows only; GUI for .NET only)

A helper class that provides a set of static Create( ) method overloads for initializing DECIMAL values in ABL.

Note: This class is used primarily by the Visual Designer during code generation. You should not expect to use this class directly.

Constructors
This class does not contain a constructor.

Super Class
This class does not inherit a super class.

Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties
This class does not contain properties (beyond those it inherits from its base class).

Public Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create( ) method (DECIMAL)</td>
<td>-</td>
</tr>
</tbody>
</table>

Public Events
This class does not contain events (beyond those it inherits from its base class).

See also
Progress.Util.DateTimeHelper class, Progress.Util.StringHelper class

Progress.Util.EnumHelper class
(Windows only; GUI for .NET only)

A helper class that provides a set of static methods you can use to perform operations on .NET enumeration types in ABL.

Constructors
This class does not contain a constructor.

Super Class
This class does not inherit a super class.

Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties
This class does not contain properties.

Public Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add( ) method</td>
<td>And( ) method</td>
</tr>
<tr>
<td>AreEqual( ) method</td>
<td>AreNotEqual( ) method</td>
</tr>
<tr>
<td>Complement( ) method</td>
<td>IsGreater( ) method</td>
</tr>
<tr>
<td>IsGreaterOrEqual( ) method</td>
<td>IsLess( ) method</td>
</tr>
</tbody>
</table>
Progress.Util.ResourceHelper class

This class does not contain events (beyond those it inherits from its base class).

Notes

- Some Progress.Util.EnumHelper methods return a System.Enum class instance. If you want to use the returned System.Enum instance as a different enumeration type, you must cast the instance to that specific type using the CAST function. For example:

```plaintext
USING System.Windows.Forms.* FROM ASSEMBLY.
USING Progress.Util.* FROM ASSEMBLY.

DEFINE VARIABLE myButton AS Button.
DEFINE VARIABLE myStyle AS System.Enum.

myButton = NEW Button().
myStyle = EnumHelper:Or( AnchorStyles:Bottom, AnchorStyles:Right ).
myButton:Anchor = CAST( myStyle, AnchorStyles ).

/* Displays "Bottom, Right" */
DISPLAY STRING( myButton:Anchor ) FORMAT "x(20)".
```

- For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.

See also
CAST function, DELETE OBJECT statement

Progress.Util.ResourceHelper class
(Windows only; GUI for .NET only)

A helper class that provides a static method you can use to retrieve the contents of a .NET XML resource (.resx) file associated with a given .NET form class.

Constructors
This class does not contain a constructor.

Super Class
This class does not inherit a super class.

Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties
This class does not contain properties (beyond those it inherits from its base class).

Public Methods

<table>
<thead>
<tr>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load() method (Class)</td>
</tr>
</tbody>
</table>

Public Events
This class does not contain events (beyond those it inherits from its base class).
### Progress.Util.StringHelper class

**Note**
For more information on using this ResourceHelper class, see the chapter on creating and using forms and controls in *OpenEdge Development: GUI for .NET Programming*.

**See also**
Progress.Windows.Form class

### Progress.Util.StringHelper class
(Windows only; GUI for .NET only)

A helper class that provides a set of static Create( ) method overloads for initializing CHARACTER values in ABL.

**Note:**
This class is used primarily by the Visual Designer during code generation. You should not expect to use this class directly.

#### Constructors
This class does not contain a constructor.

#### Super Class
This class does not inherit a super class.

#### Interfaces

This class does not contain events (beyond those it inherits from its base class).

**See also**
Progress.Util.DateTimeHelper class, Progress.Util.DecimalHelper class

### Progress.Util.TypeHelper class
(Windows only; GUI for .NET only)

A helper class that provides a static method you can use to get a System.Type instance for a .NET class using a fully-qualified class name. Use this helper class when you need to get the type of an object for which you have no instance and cannot instantiate an instance.

#### Constructors
This class does not contain a constructor.

#### Super Class
This class does not inherit a super class.

#### Interfaces
This class does not implement interfaces (beyond those it inherits from its base class).

#### Public Properties
This class does not contain properties (beyond those it inherits from its base class).
Progress.Windows.Form class

(Windows only; GUI for .NET only)

Lets you create the following types of .NET forms in an ABL session (that co-exist with traditional ABL windows and dialog boxes):

- A modal form, which is similar to an ABL modal dialog box.
- A non-modal form, which is similar to an ABL non-modal window.
- A non-modal Multiple-Document Interface (MDI) parent form, which is not supported by the traditional ABL GUI.

Constructors

PUBLIC Form()

Super Class

System.Windows.Forms.Form class (from the .NET Framework)

Interfaces

Progress.Windows.IForm interface

Public Properties

<table>
<thead>
<tr>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>NextForm property</td>
</tr>
<tr>
<td>PrevForm property</td>
</tr>
<tr>
<td>ProWinHandle property</td>
</tr>
</tbody>
</table>

Public Methods

This class does not contain methods (beyond those it inherits from its base class).

Public Events

This class does not contain events (beyond those it inherits from its base class).

Example

The following example shows a simple ABL class that inherits from Progress.Windows.Form create a non-modal form with two buttons that looks behaves like a dialog box, except that it is non-modal:
USING System.Windows.Forms.* FROM ASSEMBLY.

CLASS DemoForm INHERITS Progress.Windows.Form:

    /* Variables for buttons on the form */
    DEFINE PRIVATE VARIABLE OkBtn AS Button.
    DEFINE PRIVATE VARIABLE CancelBtn AS Button.

    CONSTRUCTOR DemoForm ( ):
        InitializeComponent( ).
    END CONSTRUCTOR.

    /* Event handlers for buttons on the form */
    METHOD PUBLIC VOID okButton_Click
        THIS-OBJECT:Close ( ).
    END METHOD.

    METHOD PRIVATE VOID cancelButton_Click
        THIS-OBJECT:Close ( ).
    END METHOD.

    /* Display and wait for this non-modal form to close.
    The caller blocks at a call to this method */
    METHOD PUBLIC VOID Wait ( ):
        WAIT-FOR Application:Run ( THIS-OBJECT ).
    END METHOD.
To instantiate DemoForm and display the non-modal form, you can run a procedure that contains the following code:

```csharp
DEFINE VARIABLE DisplayFormDemo AS CLASS DemoForm.
DisplayFormDemo = NEW DemoForm().
DisplayFormDemo:Wait().
```

For more examples, see the chapter on creating and using forms and controls in *OpenEdge Development: GUI for .NET Programming*.

**Notes**
- A modal form, which is similar to an ABL dialog box, has the following characteristics:
  - The form is displayed using the .NET ShowDialog() method invoked from a WAIT-FOR statement.
  - The form must be closed before you can access any other non-modal forms.
  - The form does not appear in the system taskbar.
  - The form typically has a dialog box border style.
Progress.Windows.Form class

- The form typically has one or more buttons to close the form (such as OK or Cancel).
- The form has no affordances in the title bar for minimizing or maximizing the form.
- The form cannot contain a menu bar.

- A non-modal form, which is similar to an ABL window, has the following characteristics:
  - The form is displayed using either the .NET Show( ) method or the Application:Run( ) method invoked from a WAIT-FOR statement.
  - The form does not prevent access to other forms.
  - The form does appear in the system taskbar.
  - The form typically has a window border style.
  - The form has affordances in the title bar for minimizing, maximizing, and closing the form.
  - The form typically contains a menu bar.

- A Multiple-Document Interface (MDI) parent form, which is the foundation for an MDI application, has the following characteristics:
  - The form is a non-modal container form.
  - The form is displayed using the .NET Application:Run( ) method invoked from a WAIT-FOR statement.
  - The form does not prevent access to other forms.
  - The form contains a main menu bar, toolbar, and status bar.
  - The form has affordances in the title bar for minimizing, maximizing, and closing the form.
  - The form does appear in the system taskbar.
  - The form has one or more associated child forms that provide for user interaction with the application. Child forms can be minimized, maximized, and resized within the MDI container.

**Note:** To associate a child form with a parent form, use the Progress.Windows.Form class to create a child form and set the child’s .NET MديParent property to the parent form.

- The form contains a client area in which all child forms are displayed.
- When a parent form is closed, the Closing events of all child forms are raised before the parent form’s Closing event is raised.

- To display a modal form, you must invoke the WAIT-FOR statement with the form’s input-blocking ShowDialog( ) method, which does the following:
  - Suspends execution of the current block.
– Prepares and displays the specified form in a wait (blocking) state until the .NET form is closed by either the user or the application.

Execution resumes after the specified form is closed.

**Note:** Unlike in a .NET application, invoking the ShowDialog( ) method in an ABL session does not, by itself, cause modal forms to display. Instead, you must invoke the WAIT-FOR statement to display these forms. For more information, see the WAIT-FOR statement (.NET objects) reference entry in this book.

For information on the .NET ShowDialog( ) method inherited from the System.Windows.Forms.Form class, refer to the .NET Framework class library.

- To display a non-modal form, you must invoke the WAIT-FOR statement with the input-blocking Application:Run( ) method, which does the following:
  
  – Suspends execution of the current block
  
  – Prepares the specified form by invoking its .NET Show( ) method
  
  – Displays the specified form in a wait (blocking) state until the form is closed by either the user or the application

  This statement will also display any additional non-modal forms that you have previously prepared by setting their Visible property to TRUE and invoking their .NET Show( ) method. After the specified form is closed, any additional non-modal forms currently displayed are also closed and execution resumes.

  If you do not specify a form, the WAIT-FOR statement displays and blocks for input on any non-modal forms that have been previously prepared by setting their Visible property to TRUE and invoking their .NET Show( ) method. In this case, all non-modal forms currently displayed can be closed and execution can resume only after the application invokes the Application:Exit( ) method.

  **Note:** Unlike in a .NET application, invoking the Show( ) method in an ABL session does not, by itself, cause non-modal forms to display. Instead, you must invoke the WAIT-FOR statement to display these forms. For more information, see the WAIT-FOR statement (.NET objects) reference entry in this book.

  For information on the .NET Show( ) and Application:Run( ) methods inherited from the System.Windows.Forms.Form class, refer to the .NET Framework class library.

- To handle a .NET form event while the WAIT-FOR statement is blocking execution, you must write and subscribe an event handler to the specified event prior to invoking the WAIT-FOR statement. For more information on event handlers for .NET events, see the “Class Events Reference” section on page 1953.

- In most cases, it is best to create a delegate class that encapsulates the form definition and related methods. For information on using delegate classes for forms, see OpenEdge Development: GUI for .NET Programming.
Progress.Windows.FormProxy class

- For information on the public class members inherited from the System.Windows.Forms.Form class, refer to the .NET Framework class library.

See also Progress.Util.ResourceHelper class, WAIT-FOR statement (.NET and ABL)

Progress.Windows/FormProxy class (Windows only; GUI for .NET only)

A .NET form wrapper for an ABL window. ABL provides a Progress.Windows/FormProxy instance for each ABL window that you create in an ABL session where a .NET form is referenced.

Note: When mixing ABL windows and .NET forms in a single application, you can access all windows and forms on a single form chain using the same form-based properties and attributes.

 Constructors This class contains a protected constructor; you cannot instantiate it directly.

 Super Class System.Object class (from the .NET Framework)

 Interfaces Progress.Windows.IForm interface

 Public Properties

<table>
<thead>
<tr>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>NextForm property</td>
</tr>
<tr>
<td>PrevForm property</td>
</tr>
<tr>
<td>ProWinHandle property</td>
</tr>
</tbody>
</table>

 Public Methods This class does not contain methods (beyond those it inherits from its base class).

 Public Events This class does not contain events (beyond those it inherits from its base class).

 Notes

- This class allows you to manage ABL windows along with .NET forms in an ABL session. It allows ABL windows to participate in the session form chain (starting with SESSION:FIRST-FORM and ending with SESSION:LAST-FORM) and to be referenced by form-oriented ABL elements such as the ACTIVE-FORM system reference. However, all program interaction with ABL windows must still be accomplished using ABL window attributes, methods, and events on the window handle (specified by the ProWinHandle property). For information on using ABL windows along with .NET forms in your application, see OpenEdge Development: GUI for .NET Programming.

- ABL does not create an instance of this class for the ABL default window, as the default window is typically not used in a GUI application.

- ABL handles all creation and destruction for instances of this class. Therefore, instances of this class never appear on the session object chain, and their NEXT-SIBLING property and PREV-SIBLING property (inherited from the Progress.Lang.Object class) are always set to the Unknown value (?)..

NextForm property PrevForm property ProWinHandle property
Progress.Windows.IForm interface

(Windows only; GUI for .NET only)

Provides for interoperability between ABL GUI windows and .NET forms. All OpenEdge .NET form-based classes in ABL implement this interface.

Public Properties

<table>
<thead>
<tr>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>NextForm property</td>
</tr>
<tr>
<td>PrevForm property</td>
</tr>
<tr>
<td>ProWinHandle property</td>
</tr>
</tbody>
</table>

Public Methods

This interface does not contain method prototypes.

Notes

- There is no need for user-defined classes to implement this interface.
- For information on the use of this interface when working with the form chain in an OpenEdge session, see *OpenEdge Development: GUI for .NET Programming*.

See also

Progress.Windows/Form class, Progress.Windows/FormProxy class

Progress.Windows.MDIChildForm class

(Windows only; GUI for .NET only)

A .NET form designed for use as an MDI child form that allows you to embed the client area of an ABL window for display in the client area of the form. This allows the widgets in the ABL client area to be displayed in the .NET MDI child form, but also allows you to interact with these widgets much as if they were still displayed in the original ABL window.

Constructor

PUBLIC MDIChildForm( INPUT mpi-parent AS Progress.Windows/Form, INPUT abl-window AS HANDLE )

*mpi-parent*

An object reference to a .NET form that you have initialized as an MDI parent form.

*abl-window*

A handle to an ABL window whose client area you want to embed in the MDI child form.

Super Class

Progress.Windows/Form class

Interfaces

This class does not implement interfaces (beyond those it inherits from its base class).
Progress.Windows.MdiChildForm class

Public Properties

<table>
<thead>
<tr>
<th>EmbeddedWindow property</th>
</tr>
</thead>
</table>

Public Methods

This class does not contain methods (beyond those it inherits from its base class).

Public Events

This class does not contain events (beyond those it inherits from its base class).

Notes

- To embed the client area of an ABL window in a .NET MDI child form, instantiate this class to create the form, setting the constructor parameters to reference the parent MDI form and the ABL window whose client area you want to embed. If you later want to change the ABL window whose client area is embedded in this form, you can set its EmbeddedWindow property to the handle of a different ABL window. Note that you can make this change only if the previous ABL window has not been realized, or after you first delete this realized window before resetting the property. For more information on how ABL supports the behavior of the ABL window and its client area embedded in a Progress.Windows.MdiChildForm, see the EmbeddedWindow property reference entry.

- The client area of a Progress.Windows.MdiChildForm is designed to contain only the ABL widgets from the client area of a single ABL window. If you want to create an MDI child form that contains the client areas of multiple ABL windows, initialize a Progress.Windows.Form object as an MDI child form and add a Progress.Windows.WindowContainer object to this form for each ABL window.

Caution: You can also add .NET controls to the client area of a Progress.Windows.MdiChildForm by using the Add( ) method on the inherited System.Windows.Forms.Control+ControlCollection inner class referenced by the inherited Controls property. However, Progress Software Corporation recommends that you do not use this method to add .NET controls to a Progress.Windows.MdiChildForm because this can result in unexpected control and form behavior.

- The menus from an embedded ABL window are not added either to the MDI child or its parent forms. You must add any associated menu and toolbar functionality to the appropriate form using corresponding .NET controls.

- The message and status areas of an embedded ABL window are not included in the MDI child form. Any messages normally displayed in the message area of the ABL window appear in an ABL alert box and any status messages normally displayed in the status area of the ABL window are ignored.

- As you resize the form, either manually or programmatically, the AVM automatically resizes the embedded client area of the ABL window to fill the client area of the Progress.Windows.MdiChildForm.

- The AVM passes all unhandled keystrokes in an embedded ABL client area to the form that contains it. This means that you can interact with menus and use menu and toolbar accelerator keys even when focus is on the embedded client area.

See also Progress.Windows.WindowContainer class
Progress.Windows.UserControl class  
(Windows only; GUI for .NET only)

A control container class that lets you combine and use a set of user-defined controls as a single control in ABL.

Constructors

PUBLIC UserControl( )

Super Class

System.Windows.Forms.UserControl class (from the .NET Framework)

Interfaces

This class does not implement interfaces (beyond those it inherits from its base class).

Public Properties

This class does not contain properties (beyond those it inherits from its base class).

Public Methods

This class does not contain methods (beyond those it inherits from its base class).

Public Events

This class does not contain events (beyond those it inherits from its base class).

Example

The following example shows a simple class that creates a user control container that contains a text box and a button:

```abl
USING System.Windows.Forms.* FROM ASSEMBLY.
CLASS DemoUserControl INHERITS Progress.Windows.UserControl:
    /* Variable for text box and button in control container */
    DEFINE PRIVATE VARIABLE TextBox AS TextBox.
    DEFINE PRIVATE VARIABLE OkBtn AS Button.

    CONSTRUCTOR DemoUserControl ( ):
        InitializeComponents( ).
    END CONSTRUCTOR.

    METHOD PRIVATE VOID InitializeComponents( ):
        /* Instantiate text box and button classes */
        TextBox = NEW TextBox ( ).
        OkBtn = NEW Button ( ).

        /* Set the text of the button, and text box */
        TextBox:Text = "Enter text here".
        OkBtn:Text = "OK".

        /* Set the size and location of the container and controls */
        TextBox:Location = NEW System.Drawing.Point(15, 20).
        OkBtn:Location = NEW System.Drawing.Point(125, 20).

        /* Add the text box and button controls to the container */
        THIS-OBJECT:Controls:Add(TextBox).
        THIS-OBJECT:Controls:Add(OkBtn).
    END METHOD.

END CLASS.
```
The following class instantiates this user control and adds it to a form:

```csharp
USING System.Windows.Forms.* FROM ASSEMBLY.

CLASS DemoUserControlForm INHERITS Progress.Windows.Form:
    /* Variable for text box and button in control container */
    DEFINE PRIVATE VARIABLE rUserControl AS DemoUserControl.

    CONSTRUCTOR DemoUserControlForm ():
        InitializeComponents ( ).
    END CONSTRUCTOR.

    /* Display and wait for this modal form to close. The caller blocks at a
call to this method */
    METHOD PUBLIC VOID Wait ( ):
        WAIT-FOR Application:Run (THIS-OBJECT).
    END METHOD.

    METHOD PRIVATE VOID InitializeComponents ( ):
        /* Instantiate user control */
        rUserControl = NEW DemoUserControl ( ).

        /* Set the text of the form title, button, and text box */
        THIS-OBJECT:Text = "This is my form".

        /* Set the location of the user control */
        rUserControl:Location = NEW System.Drawing.Point (15, 20).

        /* Add the user control to the form */
        THIS-OBJECT:Controls:Add (rUserControl).
    END METHOD.

END CLASS.

DEFINE VARIABLE rMyUIForm AS CLASS DemoUserControlForm.

rMyUIForm = NEW DemoUserControlForm ( ).
rMyUIForm:Wait ( ).
```

To instantiate DemoUserControlForm and display the form with the user control, you can run a procedure that contains the following code:

```csharp
DEFINE VARIABLE rMyUIForm AS CLASS DemoUserControlForm.

rMyUIForm = NEW DemoUserControlForm ( ).
rMyUIForm:Wait ( ).
```

For more examples, see the chapter on creating and using forms and controls in *OpenEdge Development: GUI for .NET Programming*.

**Notes**

- Once you have created an instance of a control container and added your existing controls to the container, you can add the container instance to a form as you would any single control. The controls included in the control container are displayed when the form is displayed.

- For more information on using this control container class, see the chapter on creating and using forms and controls in *OpenEdge Development: GUI for .NET Programming*.

- For information on the public class members inherited from the System.Windows.Forms.UserControl class, refer to the .NET Framework class library.

**See also**

Progress.Windows.Form class
A control container that allows you to embed the client area of an ABL window for display in a .NET form. When added to a .NET form, this container allows the embedded ABL client area to appear as though it is added directly to the client area of the .NET form. This allows the widgets in the ABL client area to be displayed in the .NET form, but also allows you to interact with these widgets much as if they were still displayed in the original ABL window.

**Constructor**

```csharp
PUBLIC WindowContainer( )
```

**Super Class**

System.Windows.Forms.UserControl class (from the .NET Framework)

**Interfaces**

This class does not implement interfaces (beyond those it inherits from its base class).

**Public Properties**

| EmbeddedWindow property | -- | -- |

**Public Methods**

This class does not contain methods (beyond those it inherits from its base class).

**Public Events**

This class does not contain events (beyond those it inherits from its base class).

**Notes**

- To embed the client area of an ABL window in a .NET form, set the EmbeddedWindow property of the WindowContainer to the handle of the ABL window and add the WindowContainer to a Progress.Windows.Form class instance. For more information on how ABL supports the behavior of the ABL window and its client area embedded in a form using a Progress.Windows.WindowContainer, see the EmbeddedWindow property reference entry.

- You can use multiple instances of this class to embed the client areas of one or more ABL windows in the client area of any single .NET form. However, a Progress.Windows.MDIChildForm is designed to embed the client area of only one ABL window that you associate with the object. For more information, see the Progress.Windows.MDIChildForm class reference entry.

- The menus from an embedded ABL window are not added to any form to which you add the WindowContainer. You must add any associated menu or toolbar functionality to the form using corresponding .NET controls.

- For any WindowContainer that you add to a Progress.Windows.Form, you must programmatically resize and reposition the WindowContainer to fit the client area of the form as it is being resized.

- When you embed the client area of an ABL window in a form, the window and its widgets do not interact directly with other .NET controls that may be added to the form. This means, for example, the embedded client area does not participate in the tab order of the form. Thus, there is no way to tab into the embedded client area from another .NET control or WindowContainer, and there is no way to tab out of the embedded client area into...

1885
another .NET control or WindowContainer. All tabbing within an embedded client area stays within the WindowContainer where it is embedded.

- The AVM passes all unhandled keystrokes in an embedded ABL client area to the form that contains it. This means that you can interact with menus and use menu and toolbar accelerator keys even when focus is on the embedded client area.

See also Progress.Windows.MDIChildForm class

System.Exception class (OpenEdge-enhanced) (Windows only; GUI for .NET only)

.NET errors are represented by error objects known as exceptions, and the .NET System.Exception class is the base class for all .NET Exception objects. To enable an ABL application to trap .NET exceptions that are raised from .NET objects, OpenEdge has enhanced System.Exception to implement the Progress.Lang.Error interface. By implementing this interface, most .NET exceptions that are raised in the ABL context can be handled by both traditional and structured ABL error handling constructs in much the same way as ABL errors.

When using structured error handling, you can catch and throw a System.Exception object and consult the same properties and methods as for a Progress.Lang.ProError class.

Constructors

Exception( )

Super Class System.Object class

Interfaces Progress.Lang.Error interface

Public Properties

CallStack property NumMessages property Severity property

Public Methods

GetName( ) method (Class) GetMessageNum( ) method

Public Events

This class does not contain events.

Notes

- Some .NET UI controls trap and handle errors before they get to the AVM. However, some kinds of exceptions, such as System.AccessViolationException, cause Application:Run( ) to terminate and raise a STOP condition on the executing WAIT-FOR or PROCESS EVENTS statement. You can trap this condition using the ON STOP phrase of an enclosing block. However, because Application:Run( ) exits and all displayed forms are closed, the most that you can do is to clean-up and attempt a graceful close of your application.

- All .NET exceptions have a Message property from the System.Exception base class. In addition, if there was a chain of errors that lead to the current exception, an InnerException property references the most recent Exception object in that chain of Exception objects,
and so on, for any number of inner exceptions. Each inner exception, then, is just another
Exception object (or something derived from it), with its own Message property. In
addition, specific types of Exception objects have additional information available from
custom properties. For example, the FileNotFoundException has a FileName property,
which is the name of the file that cannot be found.

Your ABL application can access all of the messages in the .NET Exception object (i.e.,
the message from the object itself plus any from inner exceptions) using the methods of
Progress.Lang.Error. However, if you want to access any additional information such as
the FileName custom property of the FileNotFoundException object, you must do so using
the native properties and methods of the .NET Exception object itself.

and ABL)
Class Properties and Methods Reference

This section contains reference entries that describe each built-in class property and method that ABL supports for working with ABL classes and structured error handling. Class properties and methods are mechanisms that allow you to monitor and control the behavior of class-based objects. The class properties and methods described in this section are provided by two types of OpenEdge classes:

- Built-in ABL classes that support working with user-defined ABL classes
- Built-in .NET classes that support working with .NET forms and controls

Some methods of built-in ABL classes also support .NET features, especially for handling .NET exceptions using ABL structured error handling.

For information on:

- The built-in classes provided by OpenEdge for working with both ABL and .NET classes (including structured error handling), see the “Class and Interface Reference” section on page 1851.
- Accessing class properties in ABL, see the Class-based property access reference entry.
- Calling class methods in ABL, see the Class-based method call reference entry.
Syntax for describing class method parameter and property data types

The syntax to describe the parameters of class methods in this section uses a variation of the ABL Parameter definition syntax, which includes the parameter mode and an AS option to indicate the ABL data type of the parameter:

```
INPUT value AS DECIMAL
```

**Note:** This is similar to the parameter definition syntax used to list method prototypes in the Class Browser.

A similar syntax is used to describe the parameters of .NET methods, with an optional additional notation to indicate the corresponding .NET data type. You need to know the explicit .NET data type of a .NET method parameter:

- To call an overloaded .NET method (see the Parameter passing syntax reference entry)
- When you override an inherited .NET method (see the METHOD statement reference entry)
- When you implement a method of a .NET interface (see the METHOD statement reference entry)

The ABL data type denoted by the AS option indicates how ABL treats the .NET parameter at run time. The parameter description uses the additional notation when the actual .NET data type of the parameter is a .NET mapped type other than the default match for the specified ABL data type. For information on matching .NET mapped types to ABL data types, see the Data types reference entry. If the .NET data type is not a mapped type or it is the default match for the specified ABL data type, this additional notation does not appear.

By convention throughout this section, when a particular parameter definition requires the additional notation, the syntax specifies the corresponding ABL data type and it explicitly the .NET data type mapping using an additional ABL keyword (AS data type) in parentheses (see Table 24). For example, the syntax for a .NET INPUT parameter that takes a single-precision floating-point number is represented as follows:

```
INPUT value AS DECIMAL (FLOAT)
```

Thus, the AS option for the ABL parameter definition syntax indicates the ABL DECIMAL data type, and the AS data type keyword FLOAT, which indicates an explicit .NET data type mapping to System.Single.

A similar notation is also used to document the data types of .NET method return values and .NET properties.

For more comprehensive information on mapping .NET data types to ABL data types, see OpenEdge Development: GUI for .NET Programming.
Add( ) method
(Windows only; GUI for .NET only)

Adds the underlying values of the specified enumeration types and returns the sum as a new instance.

**Return type:** System.Enum class (from the .NET Framework)

**Access:** PUBLIC STATIC

**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```
EnumHelper:Add( INPUT enum1 AS CLASS System.Enum,
               INPUT enum2 AS CLASS System.Enum )
```

**enum1**

Static reference to an enumeration value, or a reference to an enumeration type instance.

**enum2**

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type:enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:

```
```

If you want to use the returned System.Enum instance as a different enumeration type, you must cast the instance to that specific type using the CAST function.

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.

**See also:** CAST function

---

AddMessage( ) method

Add a message to the AppError object with the values from the `ErrorMessage` and `MessageNumber` arguments to the end of the message list. Your application provides the message number and text. Access error messages and message numbers with the `GetMessage( )` and `GetMessageNum( )` methods. This method increments the NumMessages property on the AppError by 1.
AllowEdit property
(Windows only; GUI for .NET only)

Indicates whether the .NET control should allow the user to edit values in the bound ABL data source object. The default value is TRUE.

You can use this property when the BindingSource object is bound to a query or a buffer. When bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.

**Data type:** LOGICAL

**Access:** PUBLIC Readable/Writeable

**Applies to:** Progress.Data.BindingSource class

Use this property only with .NET controls that support an edit operation.

**See also:** ChildAllowEdit property

AllowNew property
(Windows only; GUI for .NET only)

Indicates whether the .NET control should allow the user to add new records to the bound ABL data source object. The default value is TRUE.

You can use this property when the BindingSource object is bound to a query. When bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.

**Data type:** LOGICAL

**Access:** PUBLIC Readable/Writeable

**Applies to:** Progress.Data.BindingSource class

Use this property only with .NET controls that support an add operation.
AllowRemove property
(Windows only; GUI for .NET only)

Indicates whether the .NET control should allow the user to remove records from the bound ABL data source object. The default value is TRUE.

You can use this property when the BindingSource object is bound to a query. When bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.

Data type: LOGICAL
Access: PUBLIC Readable/Writeable
Applies to: Progress.Data.BindingSource class

Use this property only with .NET controls that support a remove operation.

See also: ChildAllowRemove property

And() method
(Windows only; GUI for .NET only)

Performs a bitwise AND operation on the underlying values of the specified enumeration types and returns a new instance. You typically use this method to check the state of a flag.

Return type: System.Enum class (from the .NET Framework)
Access: PUBLIC STATIC
Applies to: Progress.Util.EnumHelper class

Syntax

```csharp
EnumHelper:And( INPUT enum1 AS CLASS System.Enum,
                 INPUT enum2 AS CLASS System.Enum )
```

- `enum1`
  
  Static reference to an enumeration value, or a reference to an enumeration type instance.

- `enum2`
  
  Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

Syntax

```
enum-type:enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:
**AreEqual() method**  
(Windows only; GUI for .NET only)

Compares the underlying values of the specified enumeration types and returns TRUE if the values are equal. Otherwise, it returns FALSE.

**Return type:** LOGICAL  
**Access:** PUBLIC STATIC  
**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```plaintext
EnumHelper:AreEqual( INPUT enum1 AS CLASS System.Enum,  
                   INPUT enum2 AS CLASS System.Enum )
```

**enum1**

Static reference to an enumeration value, or a reference to an enumeration type instance.

**enum2**

Static reference to an enumeration value, or a reference to an enumeration type instance.
Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type:enum-member
```

Where *enum-type* is the type name of the enumeration and *enum-member* is a member name of the enumeration. For example:

```
```

See also: AreNotEqual() method

---

### AreNotEqual() method

*(Windows only; GUI for .NET only)*

Compares the underlying values of the specified enumeration types and returns TRUE if the values are not equal. Otherwise, it returns FALSE.

**Return type:** LOGICAL  
**Access:** PUBLIC STATIC  
**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```
EnumHelper:AreNotEqual( INPUT enum1 AS CLASS System.Enum, 
                        INPUT enum2 AS CLASS System.Enum )
```

*enum1*

Static reference to an enumeration value, or a reference to an enumeration type instance.

*enum2*

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type:enum-member
```

Where *enum-type* is the type name of the enumeration and *enum-member* is a member name of the enumeration. For example:

```
```
ArrayIndex property
(Windows only; GUI for .NET only)

The 1-based index position in an array field identified by the FieldIndex and FieldName properties for a SortRequestEventArgs object instance that indicates the array element on which to sort. If the field is not an array field, the value will be zero.

- **Data type:** INTEGER
- **Access:** PUBLIC Readable
- **Applies to:** Progress.Data.SortRequestEventArgs class
- **See also:**Ascending property, FieldIndex property, FieldName property, SortRequest event

Ascending property
(Windows only; GUI for .NET only)

Indicates the order in which to sort the records in the ABL data source object. TRUE indicates ascending sort order. FALSE indicates descending sort order.

- **Data type:** LOGICAL
- **Access:** PUBLIC Readable
- **Applies to:** Progress.Data.SortRequestEventArgs class
- **See also:**ArrayIndex property, FieldIndex property, FieldName property, SortRequest event

Assign( ) method
(Windows only; GUI for .NET only)

Assigns input values from the current row in the .NET control back to the corresponding record in the bound ABL data source object buffer. When a control is bound to a single field, the BindingSource object assigns the input value to the corresponding field in the buffer.

- **Return type:** LOGICAL
- **Access:** PUBLIC
- **Applies to:** Progress.Data.BindingSource class

**Syntax**

```csharp
Assign()
```

You can only use this method for validation at the row level. When a control fires a row-level event, the BindingSource object has access to the input values for all fields in the row. When a control fires a field-level event, the BindingSource object might not have access to that field’s input value.
If the method assigns values successfully, it returns TRUE; otherwise, it returns FALSE.

**Note:** This method cannot check the current values against the initial values of BLOB or CLOB fields. The method raises an error if a row contains a BLOB or a CLOB field, unless you set the ProBindingSource’s NoLOBs property to TRUE.

**See also:** NoLOBs property

AutoSort property  
(Windows only; GUI for .NET only)

Indicates whether the BindingSource object automatically sorts records in the ABL data source object when some user action in the bound .NET control generates a sort operation (such as clicking on a column header in a grid control).

You can use this property when the BindingSource object is bound to a query. If bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.

This property applies only to .NET controls that rely on their data source for sorting.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.BindingSource class

The query must have been opened with the QUERY-PREPARE and QUERY-OPEN methods (not the OPEN QUERY statement). Otherwise, the AVM generates a run-time error.

**Note:** Progress Software Corporation recommends that you open the query using the PRESELECT option, which optimizes query performance.

When TRUE, and the user initiates a sort request, the BindingSource object reopens the query associated with the ABL data source object with an appropriate BY phrase, which resorts the data in the ABL data source object. The BindingSource object replaces any existing BY phrase in the query. For more information about the BY phrase, see the OPEN QUERY statement reference entry.

When FALSE, the BindingSource object raises a SortRequest event that the application can trap and handle. If the application does not handle the event, the data in the ABL data source object is not resorted. The default value is FALSE.

If record batching is enabled (that is, the Batching property is TRUE), the BindingSource object resorts only the records in the current result set.
AutoSync property

(Windows only; GUI for .NET only)

Indicates whether the BindingSource object automatically synchronizes (refreshes) all data displayed in any bound .NET control after one of the following ABL operations on the bound ABL data source object occurs:

- Reopening the query associated with the data source using either the QUERY-PREPARE and QUERY-OPEN methods or the OPEN QUERY statement.
- Repositioning the query associated with the data source using either the REPOSITION statement or any of the REPOSITION methods.

You can use this property when the BindingSource object is bound to a query or a buffer. If bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.BindingSource class

When TRUE, the BindingSource object automatically synchronizes the data displayed in any bound .NET control. When FALSE, the application must handle this synchronization. The default value is TRUE.

Invoking the CREATE-RESULT-LIST-ENTRY( ) method or the DELETE-RESULT-LIST-ENTRY( ) method to update the result list does not cause the BindingSource object to automatically refresh the data displayed in the bound .NET controls. In this case, you can either invoke the RefreshAll( ) method or reopen the query (unless otherwise indicated).

For more information about synchronizing data, see the chapter on binding ABL data to .NET controls in *OpenEdge Development: GUI for .NET Programming*.

**See also:** Refresh( ) method, RefreshAll( ) method

AutoUpdate property

(Windows only; GUI for .NET only)

Indicates whether the BindingSource object automatically updates records in the ABL data source object when some user action in the bound .NET control generates an update operation (such as adding, removing, or editing fields).
**BandIndex property**

*(Windows only; GUI for .NET only)*

Indicates the band in a hierarchical control which uses the current record. A *band* consists of all the records at a given level in the hierarchical display. A given band might contain sets of child rows from different parent records, as shown:

```
Band 0
  Band 1
    Band 2
    Band 2
      Band 3
      Band 3
  Band 2
  Band 3
Band 1
Band 0
Band 1
Band 1
Band 0
  Band 1
    Band 2
    Band 3
      Band 3
      Band 3
  Band 2
  Band 2
  Band 1
  Band 1
  Band 1
    Band 2
    Band 2
      Band 3
      Band 3
```

This property is only set for a ProBindingSource bound to a ProDataSet with a recursive data-relation. A recursive data-relation can use a particular query in different bands. To access the correct query for the current row in this case, your application must use the BandIndex as a parameter for the data-relation’s `CURRENT-QUERY()` method.
**Note:** The BandIndex is a 0-based index.

**Data type:** INTEGER  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Data.CancelCreateRowEventArgs class, Progress.Data.CreateRowEventArgs class

The following procedure is a CreateRow event handler designed to handle a ProDataSet with a recursive data-relation. First, it checks to see if the BandIndex is 0, which always uses the top query. If not, it uses the BandIndex as the parameter for the CURRENT-QUERY() method to find the handle of the correct instance of the data-relation query.

```
PROCEDURE recursiveRelationCreateRow:

DEFINE INPUT PARAMETER sender AS System.Object.

DEFINE VARIABLE hBuffer AS HANDLE.
DEFINE VARIABLE hQuery AS HANDLE.
DEFINE VARIABLE hTopQuery AS HANDLE.
DEFINE VARIABLE hRelation AS HANDLE.

hBuffer = args:BufferHdl.
IF args:BandIndex EQ 0 THEN
  hQuery = hTopQuery.
ELSE
  hQuery = hRelation:CURRENT-QUERY(args:BandIndex).
END.

hBuffer:BUFFER-CREATE().
hQuery:CREATE-RESULT-LIST-ENTRY().
args:Created = TRUE.
END.
```

**See also:** BufferName property, CancelCreateRow event, Created property, CreateRow event

**Batching property**  
*(Windows only; GUI for .NET only)*

Indicates whether record batching is enabled for the BindingSource object. Set to TRUE to enable record batching. Set to FALSE to disable record batching. The default value is FALSE.

You can use this property when the BindingSource object is bound to a query. If bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.
BufferHdl property
(Windows only; GUI for .NET only)

For a create row operation, this is the buffer handle for the newly created row. For a cancel create row operation, this is the buffer handle to the previously created row to delete.

You can use this property when the BindingSource object is bound to a ProDataSet object. This property applies to all tables displayed in the .NET control.

When the BindingSource object is bound to a query, this property returns the Unknown value (?).

Data type: HANDLE
Access: PUBLIC Readable
Applies to: Progress.Data.CancelCreateRowEventArgs class, Progress.Data.CreateRowEventArgs class
See also: BufferName property, CancelCreateRow event, Created property, CreateRow event

BufferName property
(Windows only; GUI for .NET only)

For a create row operation, this is the buffer name for the newly created row. For a cancel create row operation, this is the buffer name of the previously created row to delete.

You can use this property when the BindingSource object is bound to a ProDataSet object. This property applies to all tables displayed in the .NET control.

When the BindingSource object is bound to a query, this property returns the Unknown value (?).
CallStack property

Contains the ABL procedure call stack at the time that a method call or property access raises an error.

Data type: CHARACTER
Access: PUBLIC Readable
Applies to: Progress.Data.CancelCreateRowEventArgs class, Progress.Data.CreateRowEventArgs class
See also: BufferHdl property, CancelCreateRow event, Created property, CreateRow event

The call stack contains one entry for each item on the stack starting with the last item, which is where the error occurred. An entry is delimited with the newline character. Each entry contains three values, separated by whitespace:

- Main block (.p), internal procedure, user-defined function, or method name
- Complete path of containing file
- Line number where the error occurred

For more information, see ERROR-STACK-TRACE attribute reference entry. For more information on -errorstack, see OpenEdge Deployment: Startup Command and Parameter Reference.

Caution: The ERROR-STACK-TRACE default value is FALSE because maintaining a call stack for error handling requires overhead that is not warranted in a production environment.
The line number in the source code file where the call was made. If there is no explicit source code line, then \textit{line-number} will be replaced by the word “IMPLICIT.” For example, if the AVM implicitly invoked a call to a super class constructor, “IMPLICIT” appears where the line number would normally appear.

\textbf{See also:} \textit{ERROR-STACK-TRACE} attribute

\textbf{ChildAllowEdit property (Windows only; GUI for .NET only)}

Indicates whether the .NET control should allow the user to edit values in the specified child temp-table buffer in the bound ABL data source object. The default value is TRUE.

Use this indexed property when the BindingSource object is bound to a ProDataSet object that contains child buffers.

\textbf{Data type:} \textit{LOGICAL}  
\textbf{Access:} PUBLIC Readable/Writeable  
\textbf{Applies to:} Progress.Data.BindingSource class

\textbf{Syntax}

\begin{verbatim}
ChildAllowEdit[ buffer-handle | buffer-name ]
\end{verbatim}

\textit{buffer-handle}

The handle to the child buffer to which this property applies.

\textit{buffer-name}

The name of the child buffer to which this property applies.

Use this property only with .NET controls that support an edit operation.
ChildAllowNew property

(Windows only; GUI for .NET only)

Indicates whether the .NET control should allow the user to add new records to the specified child temp-table buffer in the bound ABL data source object. The default value is TRUE.

Use this indexed property when the BindingSource object is bound to a ProDataSet object that contains child buffers.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.BindingSource class

**Syntax**

```
ChildAllowNew[ buffer-handle | buffer-name ]
```

*buffer-handle*

The handle to the child buffer to which this property applies.

*buffer-name*

The name of the child buffer to which this property applies.

Use this property only with .NET controls that support an add operation.

**See also:** AllowNew property

---

ChildAllowRemove property

(Windows only; GUI for .NET only)

Indicates whether the .NET control should allow the user to remove records from the specified child temp-table buffer in the bound ABL data source object. The default value is TRUE.

Use this indexed property when the BindingSource object is bound to a ProDataSet object that contains child buffers.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.BindingSource class

**Syntax**

```
ChildAllowRemove[ buffer-handle | buffer-name ]
```

*buffer-handle*

The handle to the child buffer to which this property applies.

*buffer-name*

The name of the child buffer to which this property applies.

**See also:** AllowRemove property
The name of the child buffer to which this property applies.

Use this property only with .NET controls that support a remove operation.

**See also:** AllowRemove property

---

**ChildInputValue property**

*(Windows only; GUI for .NET only)*

Returns a Progress.Data.InputValue instance containing input values for all fields in the current row of the specified child temp-table displayed in the bound .NET control. Use the indexers in this instance to access the input value of a specific field in the row.

Use this property when the BindingSource object is bound to a ProDataSet object that contains child buffers.

**Data type:** Progress.Data.InputValue class  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Data.BindingSource class

**Syntax**

```
ChildInputValue[ buffer-handle | buffer-name ]
```

**buffer-handle**

A HANDLE variable that represents the handle to the child temp-table buffer whose input values you want to access.

**buffer-name**

A CHARACTER expression that evaluates to the name of the child temp-table buffer whose input values you want to access.

The following code fragment illustrates how to use this property:

```plaintext
DEFINE VARIABLE orderInpVals AS Progress.Data.InputValue NO-UNDO.
DEFINE VARIABLE orderNum AS INTEGER NO-UNDO.

bufName = args:Row:Band:KEY.
IF bufName EQ "ttOrder" THEN DO:
  orderInpVals = myBindingSource:ChildInputValue[bufName].
  /* InputValue indexer is 0-based */
  orderNum = UNBOX(orderInpVals[0]).
  IF orderNum > 10000 THEN DO:
    MESSAGE "You have reached max number of orders."
    ...
  END.
END.
END.
```
Clear( ) method (Class)

Releases all information in a Progress.Lang.ParameterList object and sets the number of parameters to zero. Use of this method is effective for performance optimization by reusing a Progress.Lang.ParameterList object.

Return type: LOGICAL
Access: PUBLIC
Applies to: Progress.Lang.ParameterList class

Syntax

Clear( )

See also: Invoke( ) method (Class), NumParameters property, SetParameter( ) method (Class)

Clone( ) method

Creates a copy of an object instance and returns an object reference for the copy.

Return type: Progress.Lang.Object class
Access: PUBLIC
Applies to: Progress.Lang.Object class

Syntax

Clone( )

This method has no default behavior. You must override this method in a user-defined class. If you invoke this method without overriding it, ABL generates an error message and returns the Unknown value (?)

Complement( ) method
(Windows only; GUI for .NET only)

Performs a bitwise complement (NOT) operation on the underlying value of the specified enumeration type and returns a new instance. You typically use this method to unset (turn off) a flag.
**Complement( ) method**

**Return type:** System.Enum class (from the .NET Framework)

**Access:** PUBLIC STATIC

**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```
EnumHelper:Complement( INPUT enum AS CLASS System.Enum )
```

*enum*

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type:enum-member
```

Where *enum-type* is the type name of the enumeration and *enum-member* is a member name of the enumeration. For example:

```
```

The following example uses this method to invert flags:

```
USING System.Windows.Forms.* FROM ASSEMBLY.
USING Progress.Util.* FROM ASSEMBLY.

DEFINE VARIABLE rMyStyle AS System.Enum NO-UNDO.

/* Adds Bottom and Right to the list */
rMyStyle = EnumHelper:Or( AnchorStyles:Bottom, AnchorStyles:Right ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)" SKIP.
/* Displays "Bottom, Right" */

/* Sets all flags that are not set and clears all that are */
rMyStyle = EnumHelper:Complement( rMyStyle ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)" SKIP.
/* Displays "-11", which includes Top and Left but not Bottom or Right */

rMyStyle = EnumHelper:Complement( rMyStyle ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)".
/* Displays "Bottom, Right" */
```

If you want to use the returned System.Enum instance as a different enumeration type, you must cast the instance to that specific type using the CAST function.

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.
Count property
(Windows only; GUI for .NET only)

The number of records in the result set for the query associated with the top-level table displayed in the bound .NET control.

You can use this property when the BindingSource object is bound to a query or a buffer. If bound to a ProDataSet object, this property applies only to the top-level query. When bound to a buffer, the value is always 1.

**Data type:** INTEGER
**Access:** PUBLIC Readable
**Applies to:** Progress.Data.BindingSource class

**Note:** For queries with large result sets, you might want to set the MaxDataGuess property to provide bound .NET controls with a value to use for initialization. Otherwise, the ProBindingSource must read every record in the result set to provide a value for the Count property for the control to use.

**See also:** MaxDataGuess property

Create( ) method (CHARACTER)
(Windows only; GUI for .NET only)

Use this set of Create( ) method overloads to initialize CHARACTER values in ABL.

**Note:** This method is used primarily by the Visual Designer during code generation. You should not expect to use this method directly.

**Return type:** CHARACTER
**Access:** PUBLIC STATIC
**Applies to:** Progress.Util.StringHelper class

**Syntax**

```
StringHelper:Create( method-parameters )
```

**method-parameters**

A CHARACTER expression that contains one or more parameters for this method (based on the method overload).

Table 123 describes the Create( ) method overloads for initializing CHARACTER values.
The following example uses this method to initialize a CHARACTER variable with the string "AAAAAAA", and then displays the result:

```plaintext
USING Progress.Util.* FROM ASSEMBLY.
DEFINE VARIABLE aString AS CHARACTER NO-UNDO.
aString = StringHelper:Create( "A", 7 ) .
Display aString.
```

See also:  Create( ) method (DATETIME), Create( ) method (DECIMAL)

---

**Create( ) method (DATETIME)**

*(Windows only; GUI for .NET only)*

Use this set of Create( ) method overloads to initialize DATETIME values in ABL.

**Note:** This method is used primarily by the Visual Designer during code generation. You should not expect to use this method directly.

**Return type:**  DATETIME  
**Access:**  PUBLIC STATIC  
**Applies to:**  Progress.Util.DateTimeHelper class

**Syntax**

```plaintext
DateTimeHelper:Create( method-parameters )
```

**method-parameters**

A CHARACTER expression that contains one or more parameters for this method (based on the method overload).
Table 124 describes the Create( ) method overloads for initializing DATETIME values.

<table>
<thead>
<tr>
<th>Method overload syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create( INPUT ticks AS INT64 )</td>
<td>Returns a DATETIME initialized to a specified number of ticks (time values measured in 100-nanosecond units)</td>
</tr>
<tr>
<td>Create( INPUT ticks AS INT64, INPUT kind AS System.DateTimeKind )</td>
<td>Returns a DATETIME initialized to a specified number of ticks and to Coordinated Universal Time (UTC) or local time</td>
</tr>

</tr>
</tbody>
</table>

The following example uses this method to initialize a DATETIME variable with the date, July 28, 1986, and then displays the result:

```plaintext
USING Progress.Util.* FROM ASSEMBLY.
DEFINe VARIABLE aDateTime AS DATETIME NO-UNDO.

aDateTime = DateTimeHelper:Create( 1986, 7, 28 ).

Display aDateTime.
```

**See also:** Create( ) method (CHARACTER), Create( ) method (DECIMAL)

### Create( ) method (DECIMAL)

(Windows only; GUI for .NET only)

Use this set of Create( ) method overloads to initialize DECIMAL values in ABL.

**Note:** This method is used primarily by the Visual Designer during code generation. You should not expect to use this method directly.
Create( ) method (DECIMAL)

**Return type:** DECIMAL

**Access:** PUBLIC STATIC

**Applies to:** Progress.Util.DecimalHelper class

**Syntax**

```plaintext
DecimalHelper:Create( method-parameters )
```

**method-parameters**

A CHARACTER expression that contains one or more parameters for this method (based on the method overload).

Table 125 describes the Create( ) method overloads for initializing DECIMAL values.

### Table 125: Create( ) method overloads for DECIMAL values

<table>
<thead>
<tr>
<th>Method overload syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create( INPUT value AS DECIMAL (DOUBLE) )</td>
<td>Returns a DECIMAL initialized to the value of the specified double-precision floating-point number</td>
</tr>
<tr>
<td>Create( INPUT value AS INTEGER )</td>
<td>Returns a DECIMAL initialized to the value of the specified integer value</td>
</tr>
<tr>
<td>Create( INPUT value AS INTEGER EXTENT 4 )</td>
<td>Returns a DECIMAL initialized to a decimal value represented in binary and contained in a specified array</td>
</tr>
<tr>
<td>Create( INPUT value AS INT64 )</td>
<td>Returns a DECIMAL initialized to the value of the specified integer value</td>
</tr>
<tr>
<td>Create( INPUT value AS DECIMAL (FLOAT) )</td>
<td>Returns a DECIMAL initialized to the value of the specified single-precision floating-point number</td>
</tr>
<tr>
<td>Create( INPUT value AS INT64 (UNSIGNED-INTEGER) )</td>
<td>Returns a DECIMAL initialized to the value of the specified unsigned integer value</td>
</tr>
<tr>
<td>Create( INPUT value AS DECIMAL (UNSIGNED-INT64) )</td>
<td>Returns a DECIMAL initialized to the value of the specified unsigned integer value</td>
</tr>
<tr>
<td>Create( INPUT lo AS INTEGER, INPUT mid AS INTEGER, INPUT hi AS INTEGER, INPUT isNaNegative AS LOGICAL, INPUT scale AS INTEGER (UNSIGNED-BYTE) )</td>
<td>Returns a DECIMAL initialized from parameters specifying its constituent parts</td>
</tr>
</tbody>
</table>
The following example uses this method to initialize a DECIMAL variable with the value 23.45, and then displays the result:

```plaintext
USING Progress.Util.* FROM ASSEMBLY.
DEFINE VARIABLE aDecimal AS DECIMAL NO-UNDO.
aDecimal = DecimalHelper:Create( 2345, 0, 0, FALSE, 2 ).
Display aDecimal.
```

See also: Create( ) method (CHARACTER), Create( ) method (DATETIME)

---

**Created property**

(Windows only; GUI for .NET only)

Use this property in response to a CreateRow event to indicate whether the record was successfully created in the bound ABL data source object. Set to TRUE if the record was successfully created. Set to FALSE if the record was not created. The default value is TRUE.

- **Data type:** LOGICAL
- **Access:** PUBLIC Readable/Writeable
- **Applies to:** Progress.Data.CreateRowEventArgs class

If the record was successfully created in the bound ABL data source object, you must also add the record to the query’s result set using the CREATE-RESULT-LIST-ENTRY( ) method. Otherwise, the data in the control will not be synchronized with its data source.

**Caution:** After creating a row, do not reopen the query or invoke the Refresh( ) method as this might produce unexpected results.

See also: BufferHdl property, BufferName property

---

**Dispose( ) method**

(Windows only; GUI for .NET only)

Cleans up resources associated with a BindingSource object before .NET releases it from memory.

- **Return type:** VOID
- **Access:** PUBLIC
- **Applies to:** Progress.Data.BindingSource class

**Syntax**

```plaintext
Dispose( )
```

Call this method before you delete the object reference to a BindingSource instance.
Use this method especially when a BindingSource has a ProDataSet as its data source. For each row that is expanded in a hierarchical grid for a ProDataSet, the BindingSource creates a separate query. This can potentially consume a lot of memory. The ABL Virtual Machine (AVM) automatically deletes these queries when you delete the ProDataSet. However, if you want to maintain the ProDataSet beyond the scope of the BindingSource, calling the Dispose() method frees all of the memory for these queries without your having to delete the ProDataSet that is associated with them.

### EmbeddedWindow property

*(Windows only; GUI for .NET only)*

The handle to an ABL window whose client area is embedded in the client area of the specified .NET control container. This control container can be either a Progress.Windows.MdiChildForm or a Progress.Windows.WindowContainer (which you can add to any Progress.Windows.Form). After a .NET form with this embedded client area is displayed, you can interact with its ABL widgets using the supported widget attributes, methods, and events as if they were displayed in the original ABL window.

**Data type:** HANDLE  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Windows.MdiChildForm class, Progress.Windows.WindowContainer class

To reset a previously set instance of this property on a control container:

- The current ABL window referenced by this property must not yet be realized.
- If the current ABL window referenced by this property is realized, you must first delete this window before resetting the property to reference another ABL window.

Note that when you embed an ABL window in a .NET form, only the client area of the window is embedded. ABL ignores all other components of the ABL window, including border controls, menu bar, message area, and status area. For more information, see the reference entries for the Progress.Windows.MdiChildForm class and Progress.Windows.WindowContainer class.

When you embed the client area of an ABL window in a supported .NET control container, the various attributes, methods, and events of the embedded ABL window either function normally, change behavior, or have no function (are ignored), depending on the element. The following tables describe how these elements are affected by embedding the ABL window. For more information on the attributes, methods, and events of an ABL window, see the WINDOW widget reference entry.

**Note:** You can use enhanced logging to trace the occurrence of attributes and methods in your application that are ignored when you access them on an embedded ABL window. For more information, see the IgnoredOps entry type described in the LOG-ENTRY-TYPES attribute reference entry.

Table 126 lists those attributes that work on an embedded ABL window in the same way as on a non-embedded window.
Table 126: Attributes unchanged on an embedded ABL window

<tr>
<td><strong>TYPE</strong></td>
<td></td>
</tr>
<tr>
<td><strong>WINDOW</strong></td>
<td></td>
</tr>
</tbody>
</table>

1. You can specify a context help file for all frames within an embedded window by setting its **CONTEXT-HELP-FILE** attribute. However, ABL does not support the **CONTEXT-HELP** attribute for embedded windows (see Table 128). Instead, you must set the HelpButton property on the containing form in order to enable the context-help button on the form's caption bar. This containing form can be an MDI parent form, an MDI child form, or a form that contains a WindowContainer object. Note that MDI applications generally do not use the context-help feature on their forms; this feature is most commonly used in dialog boxes.

2. These attributes work on an embedded window because they apply to actions performed on the frames and field-level widgets within the window.

3. If you set the **SCROLL-BARS** attribute to TRUE on an embedded window, ABL handles the scrolling of frames within that window. The value of the AutoScroll property of the embedding form or WindowContainer has no effect on the scrolling features of these frames.

Table 127 describes attributes whose behavior on an embedded ABL window differs from how they behave on a non-embedded window.

Table 127: Attributes modified on an embedded ABL window

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Behavior changes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PARENT</strong></td>
<td>This attribute specifies the parent of a window in an ABL window hierarchy. An embedded window cannot participate in this hierarchy. So, the PARENT attribute always returns the Unknown value (?)) for an embedded window. ABL ignores any setting of this attribute on an embedded window.</td>
</tr>
<tr>
<td><strong>SENSITIVE</strong></td>
<td>The SENSITIVE attribute indicates if a widget is enabled to receive keyboard and mouse input. The default value for the SENSITIVE attribute on a window is TRUE. Setting this attribute to FALSE on an embedded window disables input to the embedded frames, but it does not disable the non-client portions of an embedding MDI child form or any form that contains a Progress.Windows.WindowContainer object. Similarly, setting VISIBLE to FALSE or HIDDEN to TRUE on an embedded window hides the embedded frames but does not hide the .NET control container into which they have been embedded.</td>
</tr>
</tbody>
</table>
Table 127: Attributes modified on an embedded ABL window

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Behavior changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>X Y ROW COLUMN</td>
<td>When queried on an embedded window, the X, Y, ROW, and COLUMN attributes return 0, 0, 1, and 1, respectively, because these attributes return position values relative to the embedded window's container. The embedded window's position is fixed at the upper-left corner of the container’s client area. ABL ignores any setting of these attributes on an embedded window. You must set the position of any Progress.Windows.WindowContainer within its containing form using appropriate .NET properties.</td>
</tr>
<tr>
<td>WIDTH-CHARS WIDTH-PIXELS</td>
<td>The WIDTH-CHARS, WIDTH-PIXELS, HEIGHT-CHARS, and HEIGHT-PIXELS window attributes return the width and height, respectively, of the client area of the embedded window, just as they do in a non-embedded window. ABL ignores any setting of these attributes on an embedded window. You must set the size of any Progress.Windows.WindowContainer within its containing form using appropriate .NET properties.</td>
</tr>
<tr>
<td>VIRTUAL-HEIGHT-CHARS</td>
<td>These attributes work for embedded windows. They determine the size of the virtual window for scrolling frames in windows. As noted for the SCROLL-BARS attribute in Table 126, ABL handles the scrolling of frames within an embedded window. For embedded windows, ABL maintains a minimum size for the virtual window; you cannot make the size of this virtual window smaller than the physical size of the embedded window container because that would cause the container to become smaller.</td>
</tr>
</tbody>
</table>

**Note:** The FULL-WIDTH-* and FULL-HEIGHT-* attributes include the size of the non-client areas of a window and, as such, are ignored for embedded windows (see Table 128).

Table 128 lists attributes on an embedded ABL window that ABL ignores. You can read or write these attributes without error, but they have no effect because their function has no meaning for the client area of an ABL window embedded in a .NET form. For the corresponding behavior in a .NET form object, use the appropriate .NET class members.

Table 128: Attributes ignored on an embedded ABL window

<td></td>
</tr>
<tr>
<td>GET-SELECTED-WIDGET( )</td>
<td>This method returns the handle of the selected frame in an embedded window.</td>
</tr>
<tr>
<td>LOAD-MOUSE-POINTER( )</td>
<td>This method specifies the mouse pointer to display when the pointer is moved over the</td>
</tr>
<tr>
<td></td>
<td>embedded frames of the window. When a window is embedded in a form, the mouse pointer</td>
</tr>
<tr>
<td></td>
<td>changes when the pointer is over these embedded frames, but it does not change when the</td>
</tr>
<tr>
<td></td>
<td>pointer is over the non-client areas of the form. If you want the non-client areas of the</td>
</tr>
<tr>
<td></td>
<td>form to have the same pointer as the embedded window, you must set the form pointer</td>
</tr>
<tr>
<td></td>
<td>separately using the Cursor property on the form.</td>
</tr>
<tr>
<td>LOAD-ICON( )</td>
<td>ABL ignores execution of these methods on an embedded window.</td>
</tr>
<tr>
<td>LOAD-SMALL-ICON( )</td>
<td></td>
</tr>
<tr>
<td>MOVE-TO-BOTTOM( )</td>
<td></td>
</tr>
<tr>
<td>MOVE-TO-TOP( )</td>
<td></td>
</tr>
</tbody>
</table>

For an embedded ABL window, ABL frame-level (ENTRY, LEAVE, etc.) and field-level events (mouse button clicks, etc.) fire normally on the embedded frames and the widgets they contain (see the “Handle-based Object Events Reference” section on page 1827). However, most window-level events do not fire because the ABL window is not visualized. You must handle .NET form events in ABL using .NET event handlers (see the “Class Events Reference” section on page 1953). Table 130 describes how ABL supports window-level events for embedded ABL windows.
### Table 130: Event support on an embedded ABL window

<table>
<thead>
<tr>
<th>Events</th>
<th>Support provided by ABL</th>
</tr>
</thead>
<tbody>
<tr>
<td>DROP-FILE-NOTIFY</td>
<td>This event fires when a file is dragged and dropped onto the client area of an embedded window whose DROP-TARGET attribute is set to TRUE.</td>
</tr>
<tr>
<td>WINDOW-RESIZED</td>
<td>This event fires whenever the embedded window container is resized, as follows:</td>
</tr>
<tr>
<td></td>
<td>• A Progress.Windows.MdiChildForm can be resized either programmatically or by the user interacting with the form on screen.</td>
</tr>
<tr>
<td></td>
<td>• A Progress.Windows.WindowContainer can be resized only programmatically, typically in response to handling a .NET form Resize event.</td>
</tr>
<tr>
<td></td>
<td>By handling the ABL WINDOW-RESIZED event in a trigger, you can resize the embedded frames and their contents to fit the new size of their container.</td>
</tr>
<tr>
<td>ENTRY</td>
<td>The AVM never generates these events for an embedded window.</td>
</tr>
<tr>
<td>LEAVE</td>
<td></td>
</tr>
<tr>
<td>PARENT-WINDOW-CLOSE</td>
<td></td>
</tr>
<tr>
<td>WINDOW-CLOSE(^1)</td>
<td></td>
</tr>
<tr>
<td>WINDOW-MAXIMIZED(^2)</td>
<td></td>
</tr>
<tr>
<td>WINDOW-MINIMIZED</td>
<td></td>
</tr>
<tr>
<td>WINDOW-RESTORED(^2)</td>
<td></td>
</tr>
</tbody>
</table>

1. As with any handle-based object, you must delete the embedded window widget when you no longer need it. You can do this in an OpenEdge GUI for .NET application, for example, by handling the .NET Closed (or FormClosed) event on the form that contains the embedded window.

2. ABL does not map the WINDOW-MAXIMIZED and WINDOW-RESTORED events from the corresponding .NET form events. However, for a Progress.Windows.MdiChildForm, the WINDOW-RESIZED event fires on the embedded window when the child form is maximized or restored.

### Equals( ) method

Compares the object reference for the current class instance to the specified object reference. If the object references (regardless of type) point to the same object instance, this method returns TRUE. Otherwise, it returns FALSE.

**Return type:** LOGICAL

**Access:** PUBLIC

**Applies to:** Progress.Lang.Object class, System.Object class (from the .NET Framework)

**Syntax**

```
Equals( INPUT OtherObj AS Progress.Lang.Object )
```

*OtherObj*

The other object reference with which to compare.
FieldIndex property
(Windows only; GUI for .NET only)

Use this property in response to a SortRequest event to indicate the 1-based index position of the field on which to sort the records in the ABL data source object.

Data type: INTEGER
Access: PUBLIC Readable
Applies to: Progress.Data.SortRequestEventArgs class

This index is based on the order of the fields as specified in the Progress.Data.BindingSource class constructor. If you specify an asterisk ("*"") in the constructor, the index is based on the order of the fields in the database record. If the field on which you are sorting is an array field, the ArrayIndex property is set to the 1-based index position of the array element on which to sort.

See also: ArrayIndex property, FieldName property, SortRequest event

FieldName property
(Windows only; GUI for .NET only)

Use this property in response to a SortRequest event to indicate the name of the field on which to sort the records in the ABL data source object.

Data type: CHARACTER
Access: PUBLIC Readable
Applies to: Progress.Data.SortRequestEventArgs class

If the field on which you are sorting is an array field, the ArrayIndex property is set to the 1-based index position of the array element on which to sort.

See also: ArrayIndex property, FieldIndex property, SortRequest event

GetClass( ) method (Progress.Lang.Class)

Returns the object reference for the Progress.Lang.Class instance associated with a specified class or interface type.

Return type: Progress.Lang.Class class
Access: PUBLIC STATIC
Applies to: Progress.Lang.Class class

Syntax

```
GetClass( object-type-name )
```

object-type-name

A CHARACTER expression that evaluates to a fully qualified object type name.
GetClass( ) method (Progress.Lang.Object)

If \textit{object-type-name} does not evaluate to a valid ABL class or interface type, this method returns the Unknown value (?)..

\textbf{Note:} Because the Progress.Lang.Class class has a private constructor, you cannot inherit from it. Therefore you must always invoke this static method using its class type name.

\section*{GetClass( ) method (Progress.Lang.Object)}

Returns the object reference for the Progress.Lang.Class instance associated with the current instance of a class.

\begin{itemize}
\item \textbf{Return type:} Progress.Lang.Class class
\item \textbf{Access:} PUBLIC
\item \textbf{Applies to:} Progress.Lang.Object class
\end{itemize}

\textbf{Syntax}

\begin{verbatim}
GetClass( )
\end{verbatim}

The Progress.Lang.Class instance returns type information on the class or interface type of the Progress.Lang.Object instance on which the method is executed.

\section*{GetMessage( ) method (Class)}

Returns the error message for the indexed error in the error object. If there is no error message at the indicated index, the method returns the empty string.

\begin{itemize}
\item \textbf{Return type:} CHARACTER
\item \textbf{Access:} PUBLIC
\item \textbf{Applies to:} Progress.Lang.ProError class, System.Exception class (OpenEdge-enhanced)
\end{itemize}

\textbf{Syntax}

\begin{verbatim}
GetMessage (INPUT MessageIndex AS INTEGER)
\end{verbatim}

\textit{MessageIndex}

The NumMessages property indicates the number of error message and number pairs in an error object. Specify an index between 1 and the value of the NumMessages property.

For a .NET System.Exception class, the information from the current object reference is used to populate message 1. If there is an InnerException, its information is used to populate message 2. This process continues down through any other nested InnerExceptions. The format of each message is:

\begin{verbatim}
Exception-Typename:Message
\end{verbatim}
For example, if you pass the value 2 to access the third member of a control collection and there are less than three elements in the collection you will get this message:

```
System.ArgumentOutOfRangeException: Index 2 is out of range
```

The string “Index 2 is out of range” is the value of the Exception Message property.

**See also:** NumMessages property, GetMessageNum( ) method

---

**GetMessageNum( ) method**

Returns the error message number associated with the indexed error in the error object.

**Return type:** INTEGER  
**Access:** PUBLIC  
**Applies to:** Progress.Lang.ProError class

**Syntax**

```
GetMessageNum (INPUT MessageIndex AS INTEGER)
```

**MessageIndex**

The NumMessages property indicates the number of error message and number pairs in an error object. Specify an index between 1 and the value of the NumMessages property.

For Progress.Lang.SysError objects, the method returns the OpenEdge message number for the system generated error. For Progress.Lang.AppError objects, the application message number returned is the number provided to the AppError( ) constructor or the AddMessage( ) method. If there is no error message at the index, the method returns the empty string.

.NET Exception objects also do not use this method.

**See also:** NumMessages property, GetMessage( ) method (Class)

---

**GetType( ) method**  
(Windows only; GUI for .NET only)

Gets a System.Type instance for a .NET class using a fully-qualified class name. Use this method when you need to get the run-time type of an object for which you have no instance and cannot instantiate an instance.

If the type cannot be found, this method returns the Unknown value (?) and optionally throws a .NET Exception.
Handle property

Return type: System.Type class (from the .NET Framework)
Access: PUBLIC STATIC
Applies to: Progress.Util.TypeHelper class

Syntax

TypeHelper:GetType( INPUT class-name AS CHARACTER [
, INPUT throw-on-error AS LOGICAL ] )

class-name

A CHARACTER express that specifies the fully-qualified name of a class.

throw-on-error

A LOGICAL expression indicating whether to throw an exception if the type cannot be found. If TRUE, the AVM throws an exception. If FALSE, the AVM will not throw an exception.

The following example gets a System.Type instance for the System.Windows.Forms.Button class:

```
USING System.Windows.Forms.* FROM ASSEMBLY.
USING Progress.Util.* FROM ASSEMBLY.
DEFINE VARIABLE btnType AS System.Type NO-UNDO.
btnType = TypeHelper:GetType( "System.Windows.Forms.Button" ).
```

Handle property
(Windows only; GUI for .NET only)

The handle to the ABL data source object to which the BindingSource object is bound. This can be a query, ProDataSet, or buffer object handle.

Data type: HANDLE
Access: PUBLIC Readable/Writeable
Applies to: Progress.Data.BindingSource class

You can use this property to associate an ABL data source object with an unbound BindingSource object instance at run time.

HasStatics( ) method

Returns TRUE if a given class has any static members. This method supports the reflection capabilities of the Progress.Lang.Class class.
HasWidgetPool() method

Returns TRUE if a given class has a widget pool. This method supports the reflection capabilities of the Progress.Lang.Class class.

**Return type:** LOGICAL
**Access:** PUBLIC
**Applies to:** Progress.Lang.Class class

**Syntax**

```
HasWidgetPool( )
```

InputValue property (Windows only; GUI for .NET only)

Returns the input value of the specified field in the current row of the top-level table displayed in the bound .NET control.

You can use this property when the BindingSource object is bound to a query or a buffer. When bound to a ProDataSet object, this property applies only to the top-level table displayed in the .NET control.

**Data type:** The data type of the corresponding buffer field.
**Access:** PUBLIC Readable
**Applies to:** Progress.Data.BindingSource class

**Syntax**

```
InputValue[ field-index | field-name ]
```

**field-index**

An INTEGER expression that evaluates to the 0-based index position of the field in the display.

**field-name**

A CHARACTER expression that evaluates to the name of the field in the display.
Invoke( ) method (Class)

Dynamically invokes a method whose name and parameters must be set at run time. The Invoke( ) method is one of several reflection methods of the Progress.Lang.Class class that provide type information about a class or interface at run time.

**Return type:** Any data type  
**Access:** PUBLIC  
**Applies to:** Progress.Lang.Class class

Four overloaded versions are supported. The first version is used to invoke a method that does not take any parameters.

**Syntax**

\[
\text{[ return-value = ] class-reference:Invoke( object-reference, method-name ).}
\]

The second overloaded version is used to invoke a method that takes zero or more parameters. Since \text{parameterlist-object} can be built with zero or more parameters, this version of the Invoke( ) method can be used to invoke any method, even those that do not take any arguments.

**Syntax**

\[
\text{[ return-value = ] class-reference:Invoke ( object-reference, method-name, parameterlist-object ).}
\]

The third overloaded version is used when invoking a static method that does not take any parameters.

**Syntax**

\[
\text{[ return-value = ] class-reference:Invoke( method-name ).}
\]

The fourth overloaded version is used when invoking a static method that takes zero or more parameters. Since \text{parameterlist-object} can be built with zero or more parameters, this version of the Invoke( ) method can be used to invoke any static method, even those that do not take any arguments.

**Syntax**

\[
\text{[ return-value = ] class-reference:Invoke ( method-name, parameterlist-object ).}
\]

Element descriptions for the syntax diagrams follow:
IsA( ) method

Returns a LOGICAL value indicating if the class type name expression or Progress.Lang.Class object passed to the method is within the class hierarchy of the Progress.Lang.Class type or implements an interface identified by the Progress.Lang.Class type. The IsA( ) method supports the reflection capabilities of the Progress.Lang.Class class.

**Return type:** LOGICAL

**Access:** PUBLIC

**Applies to:** Progress.Lang.Class class

**Syntax**

```
IsA( [ object-reference | class-type-name ] )
```
IsAbstract() method

object-reference

An object reference to a Progress.Lang.Class instance.

class-type-name

A CHARACTER expression that evaluates to a class type name.

In this example, the IsA() method is used to determine if the "Bar" class object is within the hierarchy of the "Customer" class. Note that either the object reference (custType) or the class type name ("Customer") can be passed to the method.

```
DEFINE VARIABLE b AS LOGICAL NO-UNDO.
DEFINE VARIABLE barType AS Progress.Lang.Class NO-UNDO.
DEFINE VARIABLE custType AS Progress.Lang.Class NO-UNDO.

/* Determines if "Bar" class object is within the hierarchy of "Customer" class */
ASSIGN
   barType = Progress.Lang.Class:GetClass("Bar")
   custType = Progress.Lang.Class:GetClass("Customer").

b = barType:IsA(custType).
/* or */
b = barType:IsA("Customer").
```

IsAbstract() method

Returns a LOGICAL value indicating if the specified object is a class type defined as ABSTRACT. This method supports the reflection capabilities of the Progress.Lang.Class class.

**Return type:** LOGICAL  
**Access:** PUBLIC  
**Applies to:** Progress.Lang.Class  

**Syntax**

IsAbstract( )

**See also:** CLASS statement

IsFinal() method

Returns a LOGICAL value indicating if the specified object is a class type defined as FINAL.
IsGreater() method
(Windows only; GUI for .NET only)

Compared the underlying values of the specified enumeration types and returns TRUE if the first value is greater than the second value. Otherwise, it returns FALSE.

**Return type:** LOGICAL  
**Access:** PUBLIC STATIC  
**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```csharp
EnumHelper: IsGreater( INPUT enum1 AS CLASS System.Enum,  
                        INPUT enum2 AS CLASS System.Enum )
```

- `enum1`  
  Static reference to an enumeration value, or a reference to an enumeration type instance.

- `enum2`  
  Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type: enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:

```
```

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.
IsGreaterOrEqual( ) method

See also: IsLess( ) method

IsGreaterOrEqual( ) method
(Windows only; GUI for .NET only)

Compares the underlying values of the specified enumeration types and returns TRUE if the first value is greater than or equal to the second value. Otherwise, it returns FALSE.

Return type: LOGICAL
Access: PUBLIC STATIC
Applies to: Progress.Util.EnumHelper class

Syntax

```
EnumHelper:IsGreaterOrEqual( INPUT enum1 AS CLASS System.Enum,
                INPUT enum2 AS CLASS System.Enum )
```

enum1
Static reference to an enumeration value, or a reference to an enumeration type instance.

enum2
Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

Syntax

```
enum-type:enum-member
```

Where enum-type is the type name of the enumeration and enum-member is a member name of the enumeration. For example:

```
```

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.

See also: IsLessOrEqual( ) method

IsInterface( ) method

If the specified object is defined as an interface type, this method returns TRUE. Otherwise, it returns FALSE.
IsLess() method
(Windows only; GUI for .NET only)

Compares the underlying values of the specified enumeration types and returns TRUE if the first value is less than the second value. Otherwise, it returns FALSE.

**Return type:** LOGICAL
**Access:** PUBLIC STATIC
**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```csharp
EnumHelper:IsLess( INPUT enum1 AS CLASS System.Enum,
                   INPUT enum2 AS CLASS System.Enum )
```

**enum1**

Static reference to an enumeration value, or a reference to an enumeration type instance.

**enum2**

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```csharp
enum-type:enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:

```csharp
```

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.
IsLessOrEqual( ) method
(Windows only; GUI for .NET only)

Compares the underlying values of the specified enumeration types and returns TRUE if the first value is less than or equal to the second value. Otherwise, it returns FALSE.

**Return type:** LOGICAL

**Access:** PUBLIC STATIC

**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```
EnumHelper: IsLessOrEqual( INPUT enum1 AS CLASS System.Enum,
                           INPUT enum2 AS CLASS System.Enum )
```

*enum1*

Static reference to an enumeration value, or a reference to an enumeration type instance.

*enum2*

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type: enum-member
```

Where *enum-type* is the type name of the enumeration and *enum-member* is a member name of the enumeration. For example:

```
```

For information on the `System.Enum` class and .NET enumeration types, refer to the .NET Framework class library.

See also: IsGreaterOrEqual( ) method

Load( ) method (Class)
(Windows only; GUI for .NET only)

Loads resources from a .NET XML resource (.resx) file associated with a .NET form class, and returns a `System.Resources.ResXResourceSet` instance through which you can access the resources by name.
MaxDataGuess property
(Windows only; GUI for .NET only)

An estimate of the number of records that a query will return. The property’s default value is zero.
MaxDataGuess property

**Data type:** INTEGER  
**Access:** PUBLIC Readable/Writable  
**Applies to:** Progress.Data.BindingSource class

The MaxDataGuess property offers a time-saving alternative for a ProBindingSource that binds to a query with a large result set. Some .NET controls need to know the number of records in the result set when they initialize. By default, the ProBindingSource counts the records by reading the records in the query’s result set, which can be time-consuming for large result sets. Setting this property provides the .NET control with an estimated value to bypass the counting process.

Because the .NET control used an estimated number when it visualized, you might see it readjust as the ProBindingSource’s Count property develops a more accurate count of the records. For example, you might notice the vertical scrollbar thumb of a grid changing size to more accurately reflect the number of displayed records.

When using this property, remember the following:

- Set MaxDataGuess before opening the query.
- Set MaxDataGuess before setting the ProBindingSource’s Handle property.
- The MaxDataGuess and Batching properties cannot both be TRUE at the same time. The ProBindingSource throws an exception if this happens.
- Do not open the query with the PRESELECT option. This is an exception to the normal rule with ProBindingSource queries. Since a PRESELECT query builds the entire result list, it negates the optimization from MaxDataGuess.

The following code snippet shows the correct order for using the MaxDataGuess property:

```plaintext
DEFINE VARIABLE rBindS AS Progress.Data.BindingSource NO-UNDO.
DEFINE VARIABLE hQuery AS HANDLE NO-UNDO.
ASSIGN
  rBindS = NEW Progress.Data.BindingSource()
  rBindS:MaxDataGuess = 200000.
CREATE QUERY hQuery.
  hQuery:SET-BUFFERS(BUFFER Customer:HANDLE).
  hQuery:QUERY-PREPARE("FOR EACH Customer NO-LOCK").
  hQuery:QUERY-OPEN().
  rBindS:Handle = hQuery.
```

See also: Count property
New() method

Instantiates a class when class name and any parameters are only known at run time. This method returns a Progress.Lang.Object, which provides an instance of a class. The New() method provides similar functionality to the DYNAMIC-NEW function. The advantage to the latter is that it has a fixed, compile-time parameter list and does not require the creation of a Progress.Lang.ParameterList object at run time.

**Return type:** Progress.Lang.Object class  
**Access:** PUBLIC  
**Applies to:** Progress.Lang.Class class

Two overloaded versions are supported. The first version is used when the constructor of the class does not take any arguments.

**Syntax**

```
New()
```

You can use the second overloaded version of the New() method when the constructor of a class takes zero or more parameters. Since a `parameterlist-object` can be built with zero or more parameters, this version of the New() method can be used to instantiate any class, even those classes whose constructor does not take any arguments.

**Syntax**

```
New( parameterlist-object )
```

**parameterlist-object**

An instance of the Progress.Lang.ParameterList class. The instance contains an entry for each parameter required by the constructor being invoked. It is valid to pass a Progress.Lang.ParameterList object with zero parameters if the class constructor does not take any parameters. If one or more parameters are passed, the Progress.Lang.ParameterList:setParameter() method must have been previously called on each parameter.

The AVM raises a run-time error if the Unknown value (?) is passed for `parameterlist-object`.

The New() method allows for I/O blocking.

**Notes:** Since the New() method returns an instance of the Progress.Lang.Object class, the result of the New() method must be assigned to a Progress.Lang.Object object.

The New() method must be coded as a standalone statement and not part of an ASSIGN statement.

**See also:** Clear() method (Class), DYNAMIC-INVOKE function, DYNAMIC-NEW statement, Invoke() method (Class), NEW function (classes), NEW
NewRow property
(Windows only; GUI for .NET only)

Indicates whether the current row in the bound .NET control is a new row.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Data.BindingSource class

When TRUE, the row that currently has focus is a newly created row that can still be undone. The row remains in a new state until you either move focus to another row or discard the new row. When FALSE, the current row is not a new row.

NextForm property
(Windows only; GUI for .NET only)

The next .NET form or ABL window in the chain of forms created in the current ABL session.

**Data type:** Progress.Windows.IForm  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Windows.Form class, Progress.Windows.FormProxy class, Progress.Windows.IForm interface

The chain of forms begins with SESSION:FIRST-FORM and ends with SESSION:LAST-FORM. Once your position in the chain of forms is established, you can use the NextForm and PrevForm properties to walk the chain.

**See also:** FIRST-FORM attribute, LAST-FORM attribute, PrevForm property

NEXT-SIBLING property

The object reference for the next ABL or .NET class instance in the list of instances created in the current ABL session. The value of this property is available after obtaining a valid object reference (for example, by using the SESSION:FIRST-OBJECT attribute to obtain the object reference for the first class instance in the list). If there are no class object instances in the current session, or you have gone past the last class instance in the list, this attribute returns the Unknown value (?).

**Data type:** Progress.Lang.Object class  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Lang.Object class

Once your position in the list is established, you can use the NEXT-SIBLING and PREV-SIBLING properties to walk the list of class object instances.
There are two points worth noting about this property with garbage collection enabled:

- The object references maintained by the NEXT-SIBLING property and the FIRST-OBJECT attribute do not count as references for garbage collection. That is, if a class instance is referenced only on the session object chain, it is available for automatic garbage collection.

- When an ABL object that inherits from a .NET object is on the session object chain, it can have circular references that prevent it from being deleted (as with pure ABL objects). When there are no more ABL references to such an ABL-derived .NET object, the object is removed from the object chain, but may still be instantiated because of references to it from .NET. If the application re-obtains a reference to the object in ABL by getting it from .NET, the reference is again placed on the object chain.

To check the validity of an object reference, use the VALID-OBJECT function.

See also: PREV-SIBLING property

---

**NoLOBs property**
(Windows only; GUI for .NET only)

Specifies whether or not the AVM ignores BLOB or CLOB fields while executing the ProBindingSource’s Assign( ) method or the CURRENT-CHANGED function. The default value for this property is FALSE.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable/Writable  
**Applies to:** Progress.Data.BindingSource class

The Assign( ) method and CURRENT-CHANGED function cannot check the current values against the initial values of BLOB or CLOB fields. By default, they raise an error if a row contains a BLOB or CLOB field. If the data source has BLOB or CLOB fields, you must set NoLOBs to TRUE to prevent this error.

**Caution:** If another user did change a LOB field since you read the record, the assignment might not be appropriate. You get no warning of this with NoLOBs set to TRUE. Therefore, before setting NoLOBs to TRUE, you must understand the nature of your data and be sure that setting this flag will not result in inconsistent or out-of-date data in the database.

See also: Assign( ) method, CURRENT-CHANGED function

---

**NumMessages property**

This property indicates how many error number and error message pairs are currently available in the error object.
NumParameters property

Identifies the number of parameters in a Progress.Lang.ParameterList object.

Data type: INTEGER
Access: PUBLIC Readable/Writable
Applies to: Progress.Lang.ParameterList class

This property can be updated, which has the same effect as the Clear( ) method (Class) of the Progress.Lang.ParameterList class in that all information is released. This is true even if the new number of parameters is the same as the previous number. The new list of parameters is then initialized with the new number of parameters. Each parameter returns to the non-set condition and cannot be used until a Progress.Lang.ParameterList:SetParameter( ) method is run on it.

See also: Clear( ) method (Class), New( ) method, NumParameters property, Progress.Lang.ParameterList class, SetParameter( ) method (Class)

Or( ) method
(Windows only; GUI for .NET only)

Performs a bitwise inclusive OR operation on the underlying values of the specified enumeration types and returns a new instance. You typically use this method to set (turn on) a flag.

Return type: System.Enum class (from the .NET Framework)
Access: PUBLIC STATIC
Applies to: Progress.Util.EnumHelper class

Syntax

```
EnumHelper:Or( INPUT enum1 AS CLASS System.Enum,
              INPUT enum2 AS CLASS System.Enum )
```

enum1

Static reference to an enumeration value, or a reference to an enumeration type instance.
**enum2**

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```
enum-type:enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:

```
```

The following example uses this method to set a flag:

```
USING System.Windows.Forms.* FROM ASSEMBLY.
USING Progress.Util.* FROM ASSEMBLY.

DEFINE VARIABLE rMyStyle AS System.Enum.

/* Adds Bottom and Right to the list */
rMyStyle = EnumHelper:Or( AnchorStyles:Bottom, AnchorStyles:Right ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)" SKIP.
/* Displays "Bottom, Right" */

/* Adds Top to the list */
rMyStyle = EnumHelper:Or( rMyStyle, AnchorStyles:Top ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)".
/* Displays "Top, Bottom, Right" */
```

If you want to use the returned System.Enum instance as a different enumeration type, you must cast the instance to that specific type using the CAST function.

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.

**See also:** CAST function, Xor( ) method

---

**Package property**

The package portion of the specified class or interface type name. If the class or interface type name does not contain a package, the value of this property is the Unknown value (?).
Position property

(Windows only; GUI for .NET only)

The zero-based position (index) of the current row in the bound .NET control.

Data type: INTEGER
Access: PUBLIC Readable/Writeable
Applies to: Progress.Data.BindingSource class

Whenever the value of this property changes based on some user action in the .NET control or programmatically, the BindingSource object automatically synchronizes the buffer in the bound ABL data source object to correspond to the selected row in the bound .NET control.

Note: Progress Software Corporation recommends that you do not navigate or reposition the query associated with the bound ABL data source object. For more information about synchronizing data, see OpenEdge Development: GUI for .NET Programming.

See also: PositionChanged event, Refresh( ) method

PrevForm property

(Windows only; GUI for .NET only)

The previous .NET form or ABL window in the chain of forms created in the current ABL session.

Data type: Progress.Windows.IForm
Access: PUBLIC Readable
Applies to: Progress.Windows.Form class, Progress.Windows.FormProxy class, Progress.Windows.IForm interface

The chain of forms begins with SESSION:FIRST-FORM and ends with SESSION:LAST-FORM. Once your position in the chain of forms is established, you can use the NextForm and PrevForm properties to walk the chain.
The object reference for the previous ABL or .NET class instance in the list of instances created in the current ABL session. The value of this property is available after obtaining a valid object reference (for example, by using the SESSION:LAST-OBJECT attribute to obtain the object reference for the last class instance in the list). If there are no class object instances in the current session, or you have gone past the first class instance in the list, this attribute returns the Unknown value (?).

Data type: Progress.Lang.Object class
Access: PUBLIC Readable
Applies to: Progress.Lang.Object class

Once your position in the list is established, you can use the NEXT-SIBLING and PREV-SIBLING properties to walk the list of class object instances.

There are two points worth noting about this property with garbage collection enabled:

• The object references maintained by the PREV-SIBLING property and the LAST-OBJECT attribute do not count as references for garbage collection. That is, if a class instance is referenced only on the session object chain, it is available for automatic garbage collection.

• When an ABL object that inherits from a .NET object is on the session object chain, it can have circular references that prevent it from being deleted (as with pure ABL objects). When there are no more ABL references to such an ABL-derived .NET object, the object is removed from the object chain, but may still be instantiated because of references to it from .NET. If the application re-obtains a reference to the object in ABL by getting it from .NET, the reference is again placed on the object chain.

To check the validity of an object reference, use the VALID-OBJECT function.

See also: NEXT-SIBLING property

The handle to one of the following ABL window widgets:

• The shadow window associated with a .NET form that is used for parenting relationships between ABL windows and .NET forms. ABL creates a shadow window for every .NET form that you instantiate from the Progress.Windows.Form class.

• An ABL window that is accessible from its associated Progress.Windows.FormProxy object. ABL creates an instance of this object for every ABL window that you create in a session that accesses .NET forms.

This property is used when mixing ABL windows and .NET forms in a single application.
Publish() method

**Data type:** HANDLE  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Windows.Form class, Progress.Windows.FormProxy class, Progress.Windows.IForm interface

The following example shows a class that creates and displays a .NET form and an ABL window, and parents the form to the window:

```abl
USING System.Windows.Forms.* FROM ASSEMBLY.
USING Progress.Windows.* FROM ASSEMBLY.

DEFINE VARIABLE win1 AS HANDLE NO-UNDO.
DEFINE VARIABLE form1 AS Progress.Windows.Form NO-UNDO.

/* Create a form */
form1 = NEW Progress.Windows.Form().
form1:TEXT = "Form1".
form1:Show().

/* Create a window */
CREATE WINDOW win1 ASSIGN
  TITLE = "Win1"
  HEIGHT-CHARS = 5
  WIDTH-CHARS = 35
  VISIBLE = TRUE
  SENSITIVE = TRUE.

/* Make the form the parent of the window */
win1:PARENT = form1:ProWinHandle.

WAIT-FOR Application:RUN( form1 ).
DELETE WIDGET win1.
```

For more information on using ABL windows along with .NET forms in your application, see *OpenEdge Development: GUI for .NET Programming*.

Publish() method

Publishes an ABL class event defined in the current class definition. This is a built-in event method for managing class events. For more information, see the Publish() event method reference entry.

Refresh() method  
*(Windows only; GUI for .NET only)*

Refreshes field values displayed for the current or specified row in any bound .NET control with values from the corresponding record in the bound ABL data source object.

You can use this method when the BindingSource object is bound to a query or a buffer. When bound to a ProDataSet object, this method applies only to the top-level table displayed in the .NET control.
Note: To refresh a row in a child table, you must use the RefreshAll() method.

Return type: VOID
Access: PUBLIC
Applies to: Progress.Data.BindingSource class

Syntax

```csharp
Refresh([ INPUT record-index AS INTEGER ])
```

`record-index`

An optional INTEGER value specifying a 1-based record index position in either the result set of a bound query or the top-level query in a ProDataSet object. If specified, the BindingSource object refreshes the corresponding row in any bound .NET control with values from the specified record in the bound ABL data source object. If not specified, the BindingSource object refreshes the current row in the bound .NET control (specified by the Position property) with values from the corresponding record in the bound ABL data source object.

Invoking this method does not change the editing mode of the .NET control.

See also: AutoSync property, Position property, RefreshAll() method

---

**RefreshAll() method**

*(Windows only; GUI for .NET only)*

Refreshes field values displayed for all rows (parent and child) in any bound .NET control with values from the corresponding records in the bound ABL data source object.

You can use this method when the BindingSource object is bound to a query or a buffer. When bound to a ProDataSet object, this method applies to all levels.

Note: To refresh a single row in a query, buffer, or top-level table, use the Refresh() method.

Return type: VOID
Access: PUBLIC
Applies to: Progress.Data.BindingSource class

Syntax

```csharp
RefreshAll()
```

Invoking this method does not change the editing mode of the .NET control.
RemoveMessage( ) method

Removes the indexed error (both error message string and error message number) from the message list. The method decrements the NumMessages property by 1 and moves the messages after the indexed error forward in the list by 1.

For example, if there are five messages in the AppError object’s list of messages, and the RemoveMessage method has a MessageIndex of 3, then the method removes message three. It also updates message four to be message three, and message five to be message four. Finally, it sets NumMessages to 4.

Return type: VOID
Access: PUBLIC
Applies to: Progress.Lang.AppError class

Syntax

```
RemoveMessage( INPUT MessageIndex AS INTEGER )
```

ReturnValue property

Typically, the place you programatically set the value for a RETURN or RETURN ERROR statement in an error object. The ReturnValue property, when set by the AVM, contains the error string from a RETURN ERROR statement.

If you were not using an error object, these values would usually be accessed through the RETURN-VALUE function. You would also find the values in the RETURN-VALUE function when:

- A program throws an AppError and the caller suppresses the error with the NO-ERROR option.
- The AVM creates an AppError object when encountering a RETURN ERROR ErrorString statement. ErrorString is used to populate the ReturnValue property.

Data type: CHARACTER
Access: PUBLIC Readable/Writeable
Applies to: Progress.Lang.AppError class

RowModified property
(Windows only; GUI for .NET only)

Indicates whether the current row in the bound .NET control is currently being edited.
**RowsAdded property**

When TRUE, the row that currently has focus is a newly modified row that can still be undone. The row remains in a modified state until you either move focus to another row or cancel the modification (by pressing `ESCAPE`, for example). When FALSE, the row has not been modified.

Use this property in an event handler to determine whether any data needs to be validated and saved to the ABL data source object.

**RowsAdded property (Windows only; GUI for .NET only)**

Use this property in an OffEnd event handler to indicate the number of records added to the result set from the most recent batch operation.

**SetFields( ) method (Windows only; GUI for .NET only)**

Specifies which columns are bound to a ProBindingSource instance, exposing them for bound .NET controls. You use these method overloads before you bind a data source object to a previously unbound ProBindingSource instance.

**Note:** Do not use this method on a ProBindingSource that is already bound to a data source object. The ProBindingSource throws a .NET exception if this method is used after binding to a data source object.
**SetFields() method**

**include-fields**

A CHARACTER expression that evaluates to a comma-separated list of fields in the ABL data source object to bind to the ProBindingSource. To include all fields, specify an asterisk ("*") in `include-fields`. To include all but a few fields, specify an asterisk ("*") in `include-fields` and a comma-separated list of fields to exclude in `except-fields`. If `include-fields` contains specific fields, `except-fields` is ignored.

When including fields for a ProDataSet object, you must specify a comma-separated list of fields to display in display order and qualify the field names with their buffer name. For example:

```
"table1.field1, table1.field2, table2.field1, table1.field3"
```

You must specify at least one field from each table in the hierarchy to be displayed.

When including fields for a query or a join query, you must specify a comma-separated list of fields to display in display order and you should qualify ambiguous field names with their buffer name.

Do not specify a RAW temp-table or database field in `include-fields`. If you explicitly specify a RAW field, the AVM generates a run-time error. If you specify an asterisk ("*") to include all fields and there is a RAW field in the table, the AVM excludes it automatically even if it is not specified in `except-fields`.

**except-fields**

A CHARACTER expression that evaluates to a comma-separated list of fields in the ABL data source object to exclude from binding to the ProBindingSource. You can specify fields to exclude only when `include-fields` contains an asterisk ("*"). If you do not have any fields to exclude, you must specify the empty string ("""). If `include-fields` contains specific fields, `except-fields` is ignored.

**parent-buffer-name**

A CHARACTER variable that represents the name of a parent buffer in a ProDataSet object. This corresponds to the top-level table displayed in a hierarchical control (such as a grid or a treeview). If the data source object is not a ProDataSet, this parameter must be the empty string ("""). If you specify a name and then bind to another type of data source object, the ProBindingSource throws a .NET exception.

**parent-buffer-hdl**

A HANDLE variable that represents the handle to a parent buffer in a ProDataSet object. This corresponds to the top-level table displayed in a hierarchical control (such as a grid or a treeview). If the data source object is not a ProDataSet, this parameter must be the empty string ("""). If you specify a handle and then bind to another type of data source object, the ProBindingSource throws a .NET exception.

The following code fragment shows the correct sequence for using this method:

1. Create an unbound ProBindingSource instance.
2. Use SetFields( ) to specify the appropriate columns to expose.
3. Set the ProBindingSource’s Handle property to bind the data source object.

```vbnet
DEFINE VARIABLE pbs AS Progress.Data.BindingSource NO-UNDO.
/* 1 */
pbs = NEW Progress.Data.BindingSource().
/* 2 */
/* 3 */
pbs:Handle = myQryHdl.
```

See also: Handle property

### SetParameter( ) method (Class)

**Return type:** LOGICAL  
**Access:** PUBLIC  
**Applies to:** Progress.Lang.ParameterList class

**Syntax**

```
SetParameter( position, data-type, iomode, parameter-value )
```

- **position**  
  Identifies the one-based position that the parameter occupies in the routine signature. The AVM returns a run-time error if `position` is greater than the number of parameters defined for a Progress.Lang.ParameterList object, which was set either during instantiation (passed as input to the constructor) or by setting the NumParameters attribute.

- **data-type**  
  A CHARACTER expression indicating the target parameter type. This is generally the data type that the invoked method expects, but can also be any of the extended .NET data types, such as SHORT, BYTE, SINGLE-CHARACTER, and so on.

  If the parameter of the method to be called is type DECIMAL, then `data-type` should evaluate to "DECIMAL", even if `parameter-value` evaluates to INTEGER or INT64. You can pass a type that matches the target using the same widening and hierarchy rules that are used during compilation. Using the exact target type will generally result in better performance.

  Valid `data-type` strings are: "CHARACTER", "DATASET", "DATASET-HANDLE", "DATE", "DATETIME", "DATETIME-TZ", "DECIMAL", "HANDLE", "INT64", "INTEGER", "LOGICAL", "LONGCHAR", "MEMPTR", "RAW", "ROWID", "TABLE", "TABLE-HANDLE" or "CLASS Object-Type Name". TABLE-HANDLE can be a handle to a static or dynamic TEMP-TABLE. DATASET-HANDLE can be a
severity property

handle to a static or dynamic ProDataSet object. The BUFFER type is not supported, so use the HANDLE parameters instead.

For any parameter array value, the EXTENT keyword is required when specifying data-type. For example, "CHARACTER EXTENT", "INTEGER EXTENT", "LONGCHAR EXTENT", "MEMPTR EXTENT", "CLASS Object-Type EXTENT" and so on.

For each parameter, the data type specified by the caller and the callee must be compatible with the ABL object-oriented parameter rules.

io mode

A CHARACTER expression that indicates the parameter mode and evaluates to one of the following: "INPUT", "OUTPUT", "INPUT-OUTPUT", "OUTPUT APPEND", "OUTPUT BIND", "INPUT BY-REFERENCE", "OUTPUT BY-REFERENCE", "INPUT-OUTPUT BY-REFERENCE", and "INPUT BIND". For each parameter, the mode specified by the caller and the callee must match. The AVM generates a run-time error if io mode is invalid.

Unlike the call object’s SET-PARAMETER( ) method, with the exception of "INPUT-OUTPUT", all io mode combinations are separated by a blank, for example "INPUT BY-REFERENCE".

parameter-value

A value of any data type, including the special TABLE and DATASET types. This value must be compatible with data-type. If io mode is OUTPUT or INPUT-OUTPUT, you can only specify simple variables or properties, not expressions.

See also: Clear( ) method (Class), Invoke( ) method (Class), New( ) method, NumParameters property

severity property

A convenience property intended for ABL programmers who want to rank their application error objects according to a severity scheme. Providing this property through inheritance in the base Progress.Lang.AppError class allows severity ranking without the need to subclass.

Data type: INTEGER
Access: PUBLIC Readable/Writeable
Applies to: Progress.Lang.ProError class, System.Exception class
(OpenEdge-enhanced)

Progress.Lang.SysError objects and Progress.Lang.AppError objects automatically created by the AVM as a result of a RETURN ERROR statement have no notion of error severity. For these objects, the property is set to zero (0).

.NET Exception objects also do not use this property.
SoapFault property

Identifies the SOAP-FAULT object handle that contains a SOAP fault message detail.

**Data type:** HANDLE  
**Access:** PUBLIC Readable  
**Applies to:** Progress.Lang.SoapFaultError class

If the ABL application invokes a Web service operation that returns a SOAP fault message, the AVM creates a SOAP-FAULT object. Use the SOAP-FAULT-DETAIL attribute of the SOAP-FAULT object handle to access the SOAP fault message detail.

**See also:** SOAP-fault object handle

Sorted property  
* (Windows only; GUI for .NET only)

Use this property to indicate whether you have successfully reopened the query to affect the sort based on the argument values specified in the SortRequestEventArgs object. Set to TRUE if the query was successfully reopened. Set to FALSE if the query was not reopened. The default value is TRUE.

**Data type:** LOGICAL  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.SortRequestEventArgs class  
**See also:** SortRequest event

Subscribe( ) method

Subscribes an event handler method or procedure to an ABL or .NET class event. This is a built-in event method for managing class events. For more information, see the Subscribe( ) event method reference entry.

Subtract( ) method  
* (Windows only; GUI for .NET only)

Subtracts the underlying value of the first enumeration type from the second enumeration type and returns the difference as a new instance.
SuperClass property

**Return type:** System.Enum class (from the .NET Framework)

**Access:** PUBLIC STATIC

**Applies to:** Progress.Util.EnumHelper class

**Syntax**

```csharp
EnumHelper:Subtract( INPUT enum1 AS CLASS System.Enum,
                              INPUT enum2 AS CLASS System.Enum )
```

`enum1`

Static reference to an enumeration value, or a reference to an enumeration type instance.

`enum2`

Static reference to an enumeration value, or a reference to an enumeration type instance.

Specify a static reference to an enumeration value using the following syntax:

**Syntax**

```csharp
enum-type:enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:

```csharp
```

If you want to use the returned System.Enum instance as a different enumeration type, you must cast the instance to that specific type using the CAST function.

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.

**See also:** Add( ) method, CAST function

---

SuperClass property

The object reference for the super class type information, if the user-defined class is a subclass. Otherwise, the value of this property is the Unknown value (?). If the Progress.Lang.Class is for an ABL class that inherits a .NET class, this property also returns the Unknown value (?).
TableSchema property
(Windows only; GUI for .NET only)

References a Progress.Data.TableDesc class instance that specifies schema information for the data associated with a BindingSource object.

**Note:** This property is designed for use by the Visual Designer. Though you can do so, it is not expected that you will use this in your own code.

**Data type:** Progress.Data.TableDesc class  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.BindingSource class

In the Visual Designer, when you define the logical schema (tables and fields) for a BindingSource object, the Visual Designer’s auto-generated code stores this information using the TableSchema property. At run time, the actual data source object (such as an ABL query or ProDataSet) is specified by setting the Handle property of the BindingSource. The generated code then matches up the logical schema that you defined with the data source object in order to display the correct data. For more information, see the reference entry for the Progress.Data.TableDesc class in this book.

Tag property (Progress.Data.BindingSource)  
(Windows only; GUI for .NET only)

Allows you to assign and return an arbitrary .NET object associated with a BindingSource.

**Data type:** System.Object class (from the .NET Framework)  
**Access:** PUBLIC Readable/Writeable  
**Applies to:** Progress.Data.BindingSource class

One use of this property is to store a character string containing some descriptive information about the BindingSource instance. For example, you might assign a character expression directly to this property, which ABL boxes as a System.String before assigning it to the property.

**ToString( ) method**

Returns information from the specified ABL or .NET class instance, depending on the object type.
**ToString( ) method**

**Return type:** CHARACTER  
**Access:** PUBLIC  
**Applies to:** Progress.Lang.Object class, System.Object class (from the .NET Framework)

This method is also defined on the .NET root class, System.Object, which overrides the method inherited in the ABL class structure from Progress.Lang.Object.

On an ABL class, or on an ABL-derived .NET class instance that does not override ToString( ), this method returns the fully-qualified class or interface type name of the object followed by a unique object identifier, separated by an underscore. You typically override this method in a user-defined class to provide additional contextual information.

On a pure .NET class, the information returned depends on the class type. Also, for any System.Object that boxes a .NET mapped data type (such as a System.Int32), the method returns a character string that represents the value of the mapped data type instance. (For more information on .NET mapped data types, see the Data types reference entry.) For all other .NET types, the information returned depends on how the .NET type overrides the ToString( ) method. For example, on a .NET generic type instance, the method returns a string with the following syntax:

**Syntax**

```
namespace.object-name\integer[type-name[, type-name]]
```

Where, namespace is the .NET namespace, object-name is the .NET generic class or interface name up to the left angle bracket (<) of the generic type name, integer after the backquote (’) is the number of type parameters in the generic type, and type-name is the .NET type name substituted for each type parameter in the constructed type. For more information on .NET constructed type names for generic types, see the Data types reference entry.

So, invoking the method on an instance of the following .NET generic type:

```
"System.Collection.Generic.List<CHARACTER>"
```

Returns the following string:

```
```

**Note:** This method is used by some ABL string functions and statements, such as the QUOTER and STRING functions and the MESSAGE and PUT statements.
**TypeName property**

The type name of the class or interface, which consists of the package and the class or interface name.

- **Data type:** CHARACTER
- **Access:** PUBLIC Readable
- **Applies to:** Progress.Lang.Class class
- **See also:** Type-name syntax

**Unsubscribe( ) method**

Removes a method or procedure as a handler for an ABL or .NET class event. This is a built-in event method for managing class events. For more information, see the Unsubscribe( ) event method reference entry.

**Xor( ) method**

(Windows only; GUI for .NET only)

Performs a bitwise exclusive OR operation on the underlying values of the specified enumeration types and returns a new instance. You typically use this method to toggle a flag.

- **Return type:** System.Enum class (from the .NET Framework)
- **Access:** PUBLIC STATIC
- **Applies to:** Progress.Util.EnumHelper class

**Syntax**

```csharp
EnumHelper:Xor( INPUT enum1 AS CLASS System.Enum,
                INPUT enum2 AS CLASS System.Enum )
```

- **enum1**
  
  Static reference to an enumeration value, or a reference to an enumeration type instance.

- **enum2**
  
  Static reference to an enumeration value, or a reference to an enumeration type instance.

**Specify a static reference to an enumeration value using the following syntax:**

**Syntax**

```csharp
enum-type: enum-member
```

Where `enum-type` is the type name of the enumeration and `enum-member` is a member name of the enumeration. For example:
The following example uses this method to toggle a flag:

```plaintext
USING System.Windows.Forms.* FROM ASSEMBLY.
USING Progress.Util.* FROM ASSEMBLY.
DEFINE VARIABLE rMyStyle AS System.Enum.
/* Adds Bottom and Right to the list */
rMyStyle = EnumHelper:Or( AnchorStyles:Bottom, AnchorStyles:Right ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)" SKIP.
/* Displays "Bottom, Right" */

/* Toggles a value */
rMyStyle = EnumHelper:Xor( rMyStyle, AnchorStyles:Right ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)" SKIP.
/* Displays "Bottom" */
rMyStyle = EnumHelper:Xor( rMyStyle, AnchorStyles:Right ).
DISPLAY STRING( rMyStyle ) FORMAT "x(20)" SKIP.
/* Displays "Bottom, Right" */
```

If you want to use the returned System.Enum instance as a different enumeration type, you must cast the instance to that specific type using the CAST function.

For information on the System.Enum class and .NET enumeration types, refer to the .NET Framework class library.

**See also:** CAST function, Or() method
Class Events Reference

Events are application notifications that occur as the result of run-time conditions. The ABL Virtual Machine (AVM) notifies your application of an event by executing ABL code that you define in a trigger or event handler, depending on the kind of event. ABL supports a number of built-in events that automatically result from various ABL, user, or other actions that affect an application.

You can also define your own events to notify your application of any useful condition. When you detect the occurrence of a given condition, you can notify your application of the event through an object associated with the event, which in turn executes a routine (event handler) that you have defined to respond to the event.

There are a number of factors that determine how ABL notifies your application of an event, the most important being the kind of object associated with the event. In ABL, events can be associated with the following types of objects:

- Handle-based objects
- Class-based objects

This section describes events that are associated with class-based objects (class events), including both ABL and .NET objects, and how your application can respond to them. The section also contains reference entries for built-in methods (event methods) that ABL provides to manage class events and reference entries for class events that ABL supports on built-in classes defined by OpenEdge. For more information on events associated with handle-based objects, see the “Handle-based Object Events Reference” section on page 1827.

The following descriptions refer to both compile-time and run-time behavior, which include features that the language supports and verifies at compile time and actions that result from using these features at run time. This section refers to ABL or the ABL compiler when describing compile-time features and refers to the AVM when describing run-time actions.
Class events

In ABL, class events are always defined as part of a class-based object definition, which can include one of the following object types:

- An ABL class or interface type
- A .NET class or interface type

ABL class events and .NET class events (also called .NET events) are very similar in concept, and OpenEdge allows you to manage both of them using the same ABL mechanism. Each class or interface can define any number of class events. Thus, class events are members of the class or interface for which they are defined, like methods, properties, and data members. Like any class member, a class event can be defined as either an instance or a static event, and an instance event can also be defined as abstract. A class event also has an access mode (private, protected, or public), which determines the application scope that can respond to the event.

A class event has a signature, similar to a method, that can define parameters for passing data in response to event notification. An ABL application receives notice of a class event when the object that defines the event publishes it. In an ABL application, you can subscribe one or more ABL class methods or internal procedures as event handlers, which execute when a given event is published. These event handlers must all be defined with a signature that is compatible with the event that they are subscribed to handle.

Class events provide similar features for class-based objects that named events provide for procedure-based objects, but using different mechanisms. You publish a named event using the PUBLISH statement and manage named event handler subscriptions using the SUBSCRIBE statement and UNSUBSCRIBE statement. However, you publish a class event using the Publish( ) event method and manage class event handler subscriptions using the Subscribe( ) event method and Unsubscribe( ) event method. Among the differences between the two types of events, a named event is defined when it is published and without a strongly-typed signature, while a class event must be defined before it is published and with a strongly-typed signature.

Defining class events

In ABL, you can define class events in a user-defined class or interface definition using the DEFINE EVENT statement. This statement defines all of the event options described in this section, including the signature for its event handlers.

In .NET, Common Language Specification (CLS)-compliant languages, such as C# or Visual Basic, have their own syntax to define events in a .NET class or interface. Similar to any other .NET class member, when you look up information about a .NET event in the .NET class library documentation, it typically describes the event member using syntax from one or more of these .NET languages. For example, C# provides the event keyword to declare an event in a class definition. In this way, the language-specific syntax for .NET events defines event options that are similar to the ABL DEFINE EVENT statement.

For ABL class events, you define the strongly-typed handler signature in the DEFINE EVENT statement. For .NET events, the handler signature is specified using a .NET class type known as a delegate that is referenced in the event definition. Thus, using the same delegate type, .NET objects can conveniently define multiple events whose handlers use the same signature. For an ABL class event, you can define either an ABL method signature or you can reference a .NET delegate type to define a .NET signature for the event. Referencing a .NET delegate also allows you to implement a .NET interface event or an inherited .NET abstract event in an ABL class.
You can define any valid ABL method signature for an ABL class event. However, the mechanics of event handler execution might limit your choices in practice. Also, ABL requires any .NET delegate that you use to conform to .NET conventions for event handlers.

**Defining event handlers**

To use class events in your application, you must create one or more event handlers. A class event handler can be any class method or internal procedure whose signature is compatible with the signature defined for a given ABL or .NET class event. However, verification of the event handler signature occurs at a different point for method event handlers (at handler subscription compile time) than for internal procedure event handlers (at event publish run time). Note that all class event signatures include a VOID return type; therefore, any event handler method must also have a VOID return type.

For ABL class events, including ABL class events that implement inherited .NET abstract events, if you raise ERROR or throw an error object, the error is raised on the statement that executes the `Publish()` event method on the event as if you had called the event handler directly. For information on errors raised in handlers for .NET events, see the “Defining handlers for .NET events” section on page 1955.

**Defining multiple handlers for an event**

If you need to subscribe more than one event handler for an ABL class event, when you publish the event, any OUTPUT or INPUT-OUTPUT parameter you define returns the value set by the final event handler to execute. In addition, any INPUT-OUTPUT parameter you define passes the value set by one event handler as input to the next event handler to execute. A similar effect occurs if you pass a handle or object reference as an INPUT parameter and your event handlers set the value of a public data member on the handle or class-based object. The returned value of the input object data element is the value set by the final handler to execute for the event. In addition, the order of execution for multiple handlers subscribed to a single event is not guaranteed, making it difficult or impossible to know exactly how parameter values returned from the `Publish()` method have been set. So, if you use more than one handler for a given event, you need to use caution in defining and using the parameters for that event.

Also, if you raise ERROR or throw an error object from any one of the handlers for the ABL class event, any event handler that has not already run when the error is raised does not run. Therefore, if you want all handlers to run for an event, regardless of error conditions, you must resolve all conditions within each handler and allow the handler to return successfully.

**Defining handlers for .NET events**

If you use a .NET delegate to define an ABL class event, or if you are defining an ABL method or internal procedure as a handler for a .NET event, you must define your event handler signature to match the delegate specified for the event. (In .NET, you implement event handlers by defining derivations of the specified delegate type.) For both ABL class events and .NET events, ABL only supports delegates whose signatures conform to the Microsoft .NET convention for event handler signatures. This signature convention provides for a VOID return type and two INPUT parameters, where the first parameter is a reference to a .NET `System.Object` that published the event, and the second parameter is a reference to a .NET `System.EventArgs` (or a derived class) that provides event arguments as public members of the class.
The signature for any ABL event handler defined for a .NET delegate must conform to this general syntax:

**Syntax**

```java
VOID EventHandlerName( INPUT sender AS CLASS System.Object,
                        INPUT args AS CLASS EventArgsClass )
```

*EventHandlerName*

The name of your class-based method or internal procedure.

*sender*

Object reference to the .NET class instance that published the event.

*args*

Object reference to an event arguments class that contains public properties that provide arguments for the event. Note that for a .NET event, *args* references an object that is created by .NET and added to the ABL session object chain when the event handler executes. Like any other locally scoped object reference, if you do not save the value before the event handler terminates, ABL automatically garbage collects this object at some point after the event handler returns.

*EventArgsClass*

The class type name of the event arguments class. This is always `System.EventArgs` or one of its derived classes. Thus, `System.EventArgs` is the base class for all event arguments classes that an event handler can receive through this INPUT parameter.

To identify the exact handler signature for a given .NET delegate, you must look up the delegate in the appropriate class library documentation or use the Class Browser of OpenEdge Architect to inspect the class. For .NET events supported on the built-in .NET classes provided by OpenEdge and described in the “Class and Interface Reference” section on page 1851, each event reference entry described further on in this section indicates the delegate type associated with the event along with its matching event handler signature. Otherwise, to locate the delegate in .NET class library documentation, find the event you want to handle in the documentation for the class that publishes the event. The event definition includes a reference to its delegate type. The documentation for the specified delegate shows the .NET signature you must use for your event handler.

If you do not trap and handle an error raised within a handler for a .NET event, whether it is raised as the ERROR condition or thrown as an error object, the AVM does not throw an `Exception` back to .NET, but displays an error message on the default output device and continues processing as if no error had occurred. So, unlike handlers for ABL class events, if you subscribe multiple handlers for a .NET event, all the handlers execute regardless if one or more of them raises an error.

**Using class events**

For any ABL class event, used by itself or to implement an interface or inherited abstract event, you must follow these general steps:

1. Define the event using the `DEFINE EVENT` statement.
2. Subscribe one or more handlers to the event using the `Subscribe()` event method. You can subscribe handlers to an event anywhere the event is accessible in an application.

3. Publish the event for a given condition using the `Publish()` event method, which runs all subscribed event handlers for the event. You can publish the event only from within the class definition that implements a non-abstract definition for the event.

4. Process any values returned from the `Publish()` method parameters.

At any point after subscribing event handlers, you can optionally unsubscribe any event handlers you no longer need using the `Unsubscribe()` event method. Thus, like named events for procedures, class events allow you to dynamically define and undefine alternate routines that execute in response to the event.

Note that similar to ABL class events, only the class that implements a non-abstract definition for a .NET event can publish it. This includes any ABL class that derives from and implements a .NET abstract class defining abstract events or that implements a .NET interface defining event prototypes.

However by convention, a .NET class that defines an event also typically defines a corresponding protected `OnEventName()` method that allows a derived class to publish the event, where `EventName` specifies the name of the .NET event and the signature defines a `System.EventArgs` (or derivation) as input. If the `OnEventName()` method is overrideable (`virtual` in C#), you can also override this method in an ABL derived class. If you do override this method, you must also invoke the super class implementation of `OnEventName()` from within the overriding method (using the `SUPER system reference`) in order to ensure that all subscribed .NET delegates also respond to the event. For more information on overriding .NET methods, see the `METHOD statement` reference entry.

To allow .NET events from .NET form and control objects to be published as part of the OpenEdge GUI for .NET, you must block to display the .NET forms and allow your subscribed event handlers to execute in response to any published events. To enable this .NET event handling, ABL provides `WAIT-FOR` statement syntax that blocks for both GUI for .NET events and ABL handle-based object events. For more information, see the `WAIT-FOR statement` (`.NET and ABL) reference entry.

Otherwise, you can work with .NET events in exactly the same way as ABL class events.

**Events and event methods reference**

The following reference entries document both the events of built-in ABL classes and the built-in event methods for working with all class events. The ABL built-in classes also include a set of .NET objects defined by OpenEdge. For more information on all ABL built-in classes, see the “Class and Interface Reference” section on page 1851. For information on class events defined for all other .NET objects, including the OpenEdge Ultra Controls for .NET, see the Microsoft, Infragistics®, or other third-party documentation provided for a given .NET object.

The reference entries for events that follow appear in alphabetical order by event name. Each reference entry includes the syntax required to define the signature for the event handler as a class-based method, with `EventHandlerName` used to indicate a name that you specify for the event handler. If you define the event handler as an internal procedure, define the same number of parameters in order by parameter mode and data type. If the event is a .NET event, the entry description also lists the name of the .NET delegate type defined for the event.
CancelCreateRow event
(Windows only; GUI for .NET only)

The .NET event published when some user action cancels a create row operation in the bound .NET control (for example, pressing ESCAPE in a new empty row).

Return type: VOID
Access: PUBLIC
Applies to: Progress.Data.BindingSource class
Delegate: Progress.Data.CancelCreateRowEventHandler

The delegate for this event defines the following event handler signature:

Syntax

```csharp
EventHandlerName
(
    INPUT sender AS CLASS System.Object,
    INPUT args AS CLASS Progress.Data.CancelCreateRowEventArgs
).
```

**EventHandlerName**

The name of the event handler.

**sender**

Object reference to the BindingSource object instance that published the event.

**args**

Object reference to a CancelCreateRowEventArgs object instance containing arguments for the event.

When this event occurs, delete the previously created row and the corresponding record in the result set. Otherwise, the data in the control will not be synchronized with its data source.

See also: CreateRow event, Progress.Data.CancelCreateRowEventArgs class

CreateRow event
(Windows only; GUI for .NET only)

The .NET event published when some user action initiates a create row operation in the bound .NET control (for example, clicking in a new empty row at the bottom of a control).

Return type: VOID
Access: PUBLIC
Applies to: Progress.Data.BindingSource class
Delegate: Progress.Data.CreateRowEventHandler

The delegate for this event defines the following event handler signature:
OffEnd event (.NET)

The .NET event published when record batching is enabled (that is, the BindingSource object’s Batching property is TRUE) and some user action in the bound .NET control reaches the last row of the current result set. Use this event to retrieve the next batch of records.

You can use this event when the BindingSource object is bound to a query. If bound to a ProDataSet object, this event applies only to the top-level table displayed in the .NET control.

**Return type:** VOID

**Access:** PUBLIC

**Applies to:** Progress.Data.BindingSource class

**Delegate:** Progress.Data.OffEndEventHandler

The delegate for this event defines the following event handler signature:

```csharp
EventHandlerName
(
    INPUT sender AS CLASS System.Object,
    INPUT args AS CLASS Progress.Data.CreateRowEventArgs
).
```

---

**EventHandlerName**

The name of the event handler.

**sender**

Object reference to the BindingSource object instance that published the event.

**args**

Object reference to a CreateRowEventArgs object instance containing arguments for the event.

When this event occurs, create a new record in the ABL data source object and the current result set. You can also set any initial values you want presented to the user.

If the record was successfully created, set the Created property for the CreateRowEventArgs object to TRUE (the default value). If the record was not successfully created, set the Created property to FALSE.

**Caution:** After creating a row, do not reopen the query or invoke the Refresh( ) method as this might produce unexpected results.

**See also:** CancelCreateRow event, Created property, Progress.Data.CreateRowEventArgs class
PositionChanged event

(Windows only; GUI for .NET only)

The .NET event published when the value of the Position property (which specifies the position of the current row in the bound .NET control) changes, based either on some user action in the .NET control or a programmatic action. For example:

- The user clicks on a different row in a control.
- The user clicks on a Next button and the event handler for the button increments the Position property value.

**Note:** When you click on a child row, the Position property is set to the position of the corresponding top-level parent row.

### Syntax

```
EventHandlerName
(
    INPUT sender AS CLASS System.Object,
    INPUT args AS CLASS Progress.Data.OffEndEventArgs
).
```

**EventHandlerName**

The name of the event handler.

**sender**

Object reference to the BindingSource object instance that published the event.

**args**

Object reference to an OffEndEventArgs object instance containing arguments for the event.

Each time you retrieve a batch of records, you must:

- Add the records to the current result set.
- Set the RowsAdded property for the OffEndEventArgs object to the number of records added to the result set (that is, the number of records retrieved in the most recent batch).

Once you have retrieved all of the records, set the Batching property to FALSE.

**See also:** Batching property, Progress.Data.OffEndEventArgs class, RowsAdded property
**Publish() event method**

Publishes an ABL class event defined in the current class definition. Publishing an event causes any event handlers subscribed to the event to execute.

**Return type:** VOID  
**Access:** PUBLIC  
**Applies to:** Progress.Data.BindingSource class  
**Delegate:** System.EventHandler

The delegate for this event defines the following event handler signature:

**Syntax**

```csharp
EventHandlerName
(
    INPUT sender AS CLASS System.Object,
    INPUT args AS CLASS System.EventArgs
).
```

*EventHandlerName*

The name of the event handler.

*sender*

Object reference to the BindingSource object instance that published the event.

*args*

Object reference to a .NET System.EventArgs object instance containing arguments for the event. For information on the public class members inherited from the System.EventArgs class, refer to the .NET Framework class library.

Whenever the value of the Position property changes, the BindingSource object automatically synchronizes the buffer in the bound ABL data source object to correspond to the selected row in the bound .NET control.

**Note:** Generally, you should change the Position property, rather than navigating or repositioning the query associated with the bound ABL data source object. For more information about synchronizing data, see OpenEdge Development: GUI for .NET Programming.

**See also:** Position property
Publish( ) event method

**Return type:** VOID

**Access:** PRIVATE

**Applies to:** ABL class events

**Syntax**

```
[ THIS-OBJECT : | class-type-name : ]

event-name : Publish ( [ parameter [ , parameter ] ... ] ) [ NO-ERROR ]
```

If `event-name` is a reserved keyword, you must prefix an instance `event-name` with THIS-OBJECT or a static `event-name` with the class type name of the current class definition. Otherwise use of these qualifiers is optional.

`event-name`

The name of a non-abstract event defined as part of the current class definition. At compile time, ABL verifies that `event-name` specifies an event whose DEFINE EVENT statement appears in the current class definition. This can also be the name of an inherited .NET abstract event that is implemented in the current ABL class.

```
( [ parameter [ , parameter ] ... ] )
```

Specifies zero or more parameters as defined for the event signature that you must pass to the Publish( ) method. The parameters you pass must match the parameters defined in the corresponding DEFINE EVENT statement with respect to number, data type, and mode, exactly as if you were calling a method defined with these parameters. Otherwise, ABL raises a compile-time error. Note that even if the method compiles, the AVM can raise a run-time error if an argument passed to a parameter has an ambiguous type during compilation that turns out to be incompatible at run time.

The Publish( ) method passes the same parameters to each event handler subscribed to the event. Note that any parameter results represent values returned from the last event handler to execute. However, the order of execution for event handlers is not guaranteed. Therefore, if you subscribe to multiple event handlers, you cannot be certain what event handler has returned the parameter values from the Publish( ) method.

**Caution:** Any values passed as INPUT-OUTPUT to a given event handler become input to the next event handler to execute for a given event. Because the order of handler execution for multiple event handlers is not guaranteed, you cannot be certain of the input values passed as INPUT-OUTPUT to any given event handler.

For more information on the syntax and requirements for passing each parameter, and on the behavior of parameters passed to the Publish( ) method, see the Parameter passing syntax reference entry.

**NO-ERROR**

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the ERROR-STATUS system handle. If an error occurs, the action of the statement is not completed and execution continues with the next statement. If the statement fails, any
persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be completed, depending on the order in which the AVM resolves the expression elements and the occurrence of the error.

For an ABL class event, if an event handler invoked by this method raises an error, the error is raised on this statement, and any event handlers that have not yet executed for the event do not execute. In this case, the error behavior and messages reflect the event handler that generated the error as if you called the handler directly. Note also that any STOP or QUIT condition is handled as if you called the handler directly.

Note also, if event-name is an ABL event that implements a .NET abstract event, and you invoke a .NET method within your handler that throws an exception back to .NET, .NET generates a `System.ApplicationException` that it throws back to the .NET method, which determines the result that you can manage in your handler.

To check for errors after a statement that uses the NO-ERROR option:

- Check the ERROR-STATUS:ERROR attribute to see if the AVM has raised the ERROR condition.

- Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM has generated error messages.

- Use ERROR-STATUS:GET-MESSAGE(message-num) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Following are some other important usage notes on the NO-ERROR option:

- NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

- A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

- When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, the information and messages in the error object are used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.
To access more comprehensive error information for a .NET exception, use a CATCH end block instead of the NO-ERROR option. For more information on handling .NET exceptions, see the sections on .NET error handling in OpenEdge Development: GUI for .NET Programming.

You can only invoke the Publish() method on an event from within a class definition that defines and implements the event, regardless of the event's access mode. (You cannot invoke Publish() on an abstract event.) Thus, you can publish the event within any method, constructor, destructor, property accessor, or trigger that is defined within the class that also includes the DEFINE EVENT statement that implements the event.

After the Publish() statement executes, the value of the RETURN-VALUE function reflects the last RETURN statement executed (if any) by all event handlers subscribed to event-name. However, because the order of handler execution is not guaranteed, if you subscribe more than one event handler that executes RETURN, you might not know which handler set the value for the RETURN-VALUE function.

See also: PUBLISH statement, Subscribe( ) event method, Unsubscribe( ) event method

SortRequest event
(Windows only; GUI for .NET only)

The .NET event published when some user action initiates a sort operation in the bound .NET control (for example, clicking on a column header in a grid control).

You can use this event when the BindingSource object is bound to a query or a buffer. If bound to a ProDataSet object, this event applies only to the top-level table displayed in the .NET control.

Return type: VOID
Access: PUBLIC
Applies to: Progress.Data.BindingSource class
Delegate: Progress.Data.SortRequestEventHandler

The delegate for this event defines the following event handler signature:

Syntax

```
EventHandlerName
(

    INPUT sender AS CLASS System.Object,
    INPUT args AS CLASS Progress.Data.SortRequestEventArgs

).
```

`EventHandlerName`

The name of the event handler.

`sender`

Object reference to the BindingSource object instance that published the event.
subscribe event method

Object reference to a SortRequestEventArgs object instance containing arguments for the event.

When this event occurs, the event handler must reopen the query associated with the ABL data source object with a modified sort criteria based on the values specified in the SortRequestEventArgs object.

This event occurs only for .NET controls that rely on their data source for sorting.

See also: Progress.Data.SortRequestEventArgs class

Subscribe( ) event method

Subscribes an event handler method or procedure to an ABL or .NET class event.

Return type: VOID
Access: PUBLIC
Applies to: ABL or .NET class events

Syntax

\[
\begin{align*}
\text{publisher: } & \text{event-name:Subscribe} \\
& \left( \text{subscriber: } \text{handler-method} \right) \text{ NO-ERROR }
\end{align*}
\]

The object reference to an ABL or .NET object or the type name of an ABL or .NET class that can publish the instance or static event, respectively. If you do not specify a publisher, it defaults to either THIS-OBJECT when event-name identifies an instance event defined in the current class instance, or to the class type name of the current class definition when event-name identifies a static event defined in the current class hierarchy.

event-name

The name of an ABL or .NET event that publisher can publish. At compile time, ABL verifies that event-name is an accessible member of the class referenced by publisher. The event can be an abstract event.

subscriber: ] handler-method

An ABL class-based method that you want to subscribe as a handler for event-name, where handler-method is the unquoted name of a pure ABL instance or static method. If specified, subscriber can be either the object reference to an ABL class instance where handler-method is defined, or the type name of an ABL class where the static handler-method is defined. If you do not specify a subscriber, it defaults to either
THIS-OBJECT when \textit{handler-method} identifies an instance method defined in the current class hierarchy, or to the class type name of the current class definition when \textit{handler-method} identifies a static method defined in the current class hierarchy.

\textbf{Note:} The specified \textit{handler-method} cannot be a .NET method.

Note that the access mode (PUBLIC, PROTECTED, or PRIVATE) of the \textit{handler-method} definition does not matter to the \textit{publisher}. For example, you can subscribe a PRIVATE method of the subscribing class instance as a handler to an event defined and published by yet another class instance.

The signature of \textit{handler-method} does not have to be identical with the signature defined for \textit{event-name}, but it must be run-time compatible. This includes an overloaded method as long as ABL can identify the signature for a unique overloading that is compatible with the event signature.

Thus, ABL raises a compile-time error if \textit{handler-method}:

- Is not accessible to the context where this \texttt{Subscribe( )} method executes
- Does not have a run-time compatible signature
- Does not have a unique overloading that is compatible with the event signature

\begin{verbatim}
[ subscriber-handle , ] handler-procedure
\end{verbatim}

A procedure that you want to subscribe as a handler for \textit{event-name}, where \textit{handler-procedure} is a character expression that evaluates to the name of an internal procedure. If specified, \texttt{subscriber-handle} is a handle to a persistent procedure, or any other external procedure on the call stack, where the internal procedure is defined. Otherwise, \texttt{subscriber-handle} defaults to \texttt{THIS-PROCEDURE}.

At compile-time, ABL checks this \texttt{Subscribe( )} method call only to verify that any specified \texttt{subscriber-handle} is a HANDLE data type and that \textit{handler-procedure} is specified by a character expression. Otherwise, the AVM raises a run-time error if the procedure context specified by \texttt{subscriber-handle} is not accessible or it does not define \textit{handler-procedure} as an internal procedure.

\texttt{NO-ERROR}

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the \texttt{ERROR-STATUS} system handle. If an error occurs, the action of the statement is not completed and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be completed, depending on the order in which the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the \texttt{NO-ERROR} option:

- Check the \texttt{ERROR-STATUS:ERROR} attribute to see if the AVM raised the \texttt{ERROR} condition.
• Check if the ERROR-STATUS:NUM-MESSAGES attribute is greater than zero to see if the AVM has generated error messages.

• Use ERROR-STATUS:GET-MESSAGE(message-num) to retrieve a particular message, where message-num is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Following are some other important usage notes on the NO-ERROR option:

• NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

• A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the ERROR-STATUS system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

• When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

• If an error object is thrown to a statement that includes the NO-ERROR option, the information and messages in the error object are used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

• To access more comprehensive error information for a .NET exception, use a CATCH end block instead of the NO-ERROR option. For more information on handling .NET exceptions, see the sections on .NET error handling in OpenEdge Development: GUI for .NET Programming.

The Subscribe( ) method subscribes the specified method or internal procedure to the specified event-name by adding its name to a list of handlers for the event. If you do not specify a publisher, you can only invoke Subscribe( ) in an ABL class definition and on an ABL or .NET event that the ABL class defines or inherits. Note that you can subscribe the same event handler to two different events as long as the signatures are compatible. However, you can subscribe any given event handler only once to the same event. Each time an event is published, all subscribed event handlers execute once in no guaranteed order.

See also: Publish( ) event method, SUBSCRIBE statement, Unsubscribe( ) event method

Unsubscribe( ) event method

Removes a method or procedure as a handler for an ABL or .NET class event.
Unsubscribe( ) event method

**Return type:** VOID  
**Access:** PUBLIC  
**Applies to:** ABL or .NET class events

### Syntax

| publisher : | event-name:Unsubscribe  
| ( | subscriber : | handler-method | ) | NO-ERROR |

| publisher : | event-name:Unsubscribe  
| ( | subscriber-handle, | handler-procedure | ) | NO-ERROR |

| publisher : |

The object reference to an ABL or .NET object or the type name of an ABL or .NET class that can publish the instance or static event, respectively. If you do not specify a `publisher`, it defaults to either THIS-OBJECT when `event-name` identifies an instance event defined in the current class instance, or to the class type name of the current class definition when `event-name` identifies a static event defined in the current class hierarchy.

**event-name**

The name of an ABL or .NET event that `publisher` can publish. At compile time, ABL verifies that `event-name` is an accessible member of the class referenced by `publisher`. The event can be an abstract event.

| subscriber : | handler-method |

An ABL class-based method that you want to remove as a handler for `event-name`, where `handler-method` is the unquoted name of the instance or static method. If specified, `subscriber` can be either the object reference to an ABL class instance where `handler-method` is defined, or the type name of an ABL class where the static `handler-method` is defined. If you do not specify a `subscriber`, it defaults to THIS-OBJECT when `handler-method` identifies an instance method defined in the current class hierarchy, or to the class type name of the current class definition when `handler-method` identifies a static method defined in the current class hierarchy.

Note that the access mode (PUBLIC, PROTECTED, or PRIVATE) of the `handler-method` definition does not matter to the `publisher`. For example, you can remove a PRIVATE method of the unsubscribing class instance as a handler for an event defined and published by yet another class instance.

The signature of `handler-method` must be run-time compatible with the signature defined for `event-name`. This includes an overloaded method as long as ABL can identify the signature for a unique overloading that is compatible with the event signature.

Thus, ABL raises a compile-time error if `handler-method`:

- Is not accessible to the context where this `Unsubscribe( )` method executes
- Does not have a run-time compatible signature
• Does not have a unique overloading that is compatible with the event signature

\[
[ \text{subscriber-handle}, ] \text{handler-procedure}
\]

A procedure that you want to remove as a handler for \text{event-name}, where \text{handler-procedure} is a character expression that evaluates to the name of an internal procedure. If specified, \text{subscriber-handle} is a handle to a persistent procedure, or other external procedure on the call stack, where the internal procedure is defined. Otherwise, \text{subscriber-handle} defaults to THIS-PROCEDURE.

At compile-time, ABL checks this Unsubscribe( ) method call only to verify that any specified \text{subscriber-handle} is a HANDLE data type and that \text{handler-procedure} is specified by a character expression. Otherwise, ABL raises a run-time error if the procedure context specified by \text{subscriber-handle} is not accessible or it does not define \text{handler-procedure} as an internal procedure.

\text{NO-ERROR}

Suppresses ABL errors or error messages that would otherwise occur and diverts them to the \text{ERROR-STATUS} system handle. If an error occurs, the action of the statement is not completed and execution continues with the next statement. If the statement fails, any persistent side-effects of the statement are backed out. If the statement includes an expression that contains other executable elements, like methods, the work performed by these elements may or may not be completed, depending on the order in which the AVM resolves the expression elements and the occurrence of the error.

To check for errors after a statement that uses the NO-ERROR option:

• Check the \text{ERROR-STATUS:ERROR} attribute to see if the AVM raised the ERROR condition.

• Check if the \text{ERROR-STATUS:NUM-MESSAGES} attribute is greater than zero to see if the AVM has generated error messages.

• Use \text{ERROR-STATUS:GET-MESSAGE( message-num )} to retrieve a particular message, where \text{message-num} is 1 for the first message.

If the statement does not include the NO-ERROR option, you can use a CATCH end block to handle errors raised by the statement.

Following are some other important usage notes on the NO-ERROR option:

• NO-ERROR does not suppress errors that raise the STOP or QUIT condition.

• A CATCH statement, which introduces a CATCH end block, is analogous to a NO-ERROR option in that it also suppresses errors, but it does so for an entire block of code. It is different in that the error messages are contained in a class-based error object (generated by the AVM or explicitly thrown), as opposed to the \text{ERROR-STATUS} system handle. Also, if errors raised in the block are not handled by a compatible CATCH block, ON ERROR phrase, or UNDO statement, then the error is not suppressed, but handled with the default error processing for that block type.

• When a statement contains the NO-ERROR option and resides in a block with a CATCH end block, the NO-ERROR option takes precedence over the CATCH block. That is, an error raised on the statement with the NO-ERROR option will not
be handled by a compatible CATCH end block. The error is redirected to the ERROR-STATUS system handle as normal.

- If an error object is thrown to a statement that includes the NO-ERROR option, the information and messages in the error object are used to set the ERROR-STATUS system handle. This interoperability feature is important for those integrating code that uses the traditional NO-ERROR technique with the newer, structured error handling that features error objects and CATCH end blocks.

- To access more comprehensive error information for a .NET exception, use a CATCH end block instead of the NO-ERROR option. For more information on handling .NET exceptions, see the sections on .NET error handling in *OpenEdge Development: GUI for .NET Programming*.

The **Unsubscribe()** method cancels an event subscription by removing the specified method or internal procedure from the list of handlers for the specified *event-name*. If you do not specify a *publisher*, you can only invoke **Unsubscribe()** in an ABL class definition and on an ABL or .NET event that the ABL class defines or inherits. When you cancel an event handler subscription, ABL does not raise either a run-time error if the specified event handler is not currently on the subscription list for the specified event.

**See also:** *Publish( )* event method, *Subscribe( )* event method, UNSUBSCRIBE statement
The following table lists all keywords and built-in object names in ABL. Built-in object names for procedure or database objects are listed in all lower case. The columns are as follows:

- **Keyword** — Specifies the full keyword or built-in object name.
- **Rsrv** — Indicates whether a keyword is reserved.
- **Minimum abbreviation** — Specifies the shortest abbreviation ABL recognizes for the keyword or name. If no abbreviation is specified, the keyword cannot be abbreviated.
