<b>Preface.....</b>	<b>11</b>
Progress Corticon documentation.....	11
Overview of Progress Corticon.....	13
 <b>Chapter 1: Building the Vocabulary.....</b>	<b>15</b>
What is a Vocabulary?.....	15
Starting from scratch.....	17
Designing the Vocabulary.....	18
Step 1 – Identify the Terms .....	18
Step 2 – Separating the Generic Terms from the Specific .....	19
Step 3 – Assembling and Relating the Terms .....	19
Step 4 – Diagramming the Vocabulary.....	20
Modeling the Vocabulary in Corticon Studio.....	21
Importing an OpenEdge Business Rules Vocabulary Definition (BRVD) file.....	23
Locking and unlocking Corticon Vocabularies.....	25
Applying an updated BRVD to a Vocabulary.....	27
Custom Data Types.....	30
Constraint Expressions.....	30
Using non-enumerated Custom Data Types in Rulesheets and Ruletests.....	32
Enumerations.....	33
Enumerations defined in the Vocabulary .....	33
Enumerations retrieved from a database.....	35
Using Custom Data Types in a Vocabulary.....	38
Using enumerated Custom Data Types in Rulesheets.....	38
Using enumerated Custom Data Types in Ruletests.....	39
Relaxing enforcement of Custom Data Types.....	39
Domains.....	42
Domains in a Rulesheet.....	43
Domains in a Ruletest.....	43
Support for inheritance.....	44
Inherited Attributes .....	45
Inherited Associations .....	45
Controlling the tree view.....	46
Using aliases with inheritance.....	46
Inheritance's effects on rule execution.....	47
Inheritance and Java object messaging.....	50
Test yourself - questions – building the vocabulary.....	51

---

<b>Chapter 2: Rule scope &amp; context.....</b>	<b>55</b>
Rule scope.....	61
Aliases.....	64
Scope and perspectives in the vocabulary tree.....	65
Roles.....	67
Technical aside.....	72
Test yourself: Rule scope and context.....	73
 <b>Chapter 3: Rule writing techniques – logical equivalents.....</b>	 <b>79</b>
Filters vs. conditions.....	79
Boolean condition Vs. values set.....	81
Exclusionary syntax.....	82
Using "other" in condition cells.....	83
Use of ranges in condition cells.....	84
Alternatives to value ranges.....	86
Standard boolean constructions.....	86
Test yourself - questions – rule writing techniques – logical equivalents.....	87
 <b>Chapter 4: Collections.....</b>	 <b>89</b>
Understanding how Corticon Studio handles collections.....	90
Visualizing collections.....	90
A basic collection operator.....	91
Filtering collections.....	92
Using aliases to represent collections.....	92
Sorted aliases.....	101
Singletons.....	104
Special collection operators.....	107
Universal quantifier.....	108
Existential quantifier.....	110
Another example using the existential quantifier.....	113
Aggregations that optimize database access.....	119
Test yourself - questions – collections.....	119
 <b>Chapter 5: Rules containing calculations &amp; equations.....</b>	 <b>123</b>
Terminology.....	123
Operator precedence.....	124
Datatype compatibility and casting.....	124
Datatype of an expression.....	127
Defeating the parser.....	128
Manipulating datatypes with casting operators.....	128
Supported uses of calculation expressions.....	130

Calculation as a comparison in a precondition.....	131
Calculation as an assignment in a noncondition.....	132
Calculation as a comparison in a condition.....	132
Calculation as an assignment in an action.....	134
Unsupported uses of calculation expressions.....	134
Calculations in value sets and column cells.....	134
Calculations in rule statements.....	135
Test yourself - questions – rules containing calculations and equations.....	135

## **Chapter 6: Rule dependency: Chaining and looping.....139**

What is rule dependency?.....	139
Forward chaining.....	140
Rulesheet processing: modes of looping.....	141
Types of loops.....	142
Looping controls in Corticon Studio.....	146
Identifying loops.....	146
The loop detection tool.....	146
Removing loops.....	147
Terminating infinite loops.....	148
Looping example.....	148
Problem .....	148
Solution .....	149
Using conditions as a processing threshold.....	152
Test yourself - questions – Rule dependency: chaining and looping.....	154

## **Chapter 7: Filters & preconditions .....157**

What is a filter?.....	158
Full filters.....	160
Limiting filters.....	162
Database filters.....	168
What is a precondition?.....	169
Summary of filter and preconditions behaviors.....	174
Performance implications of the precondition behavior.....	174
Using collection operators in a filter.....	176
Location matters.....	177
Multiple filters on collections.....	180
Filters that use OR.....	183
Test yourself - questions – filters & preconditions.....	183

## **Chapter 8: Recognizing and modeling parameterized rules.....187**

Parameterized rule where a specific attribute is a variable (or parameter) within a general business rule.....	187
Parameterized rule where a specific business rule is a parameter within a generic business rule.....	189

Populating an AccountRestriction table from a sample user interface .....	191
Test yourself - questions – recognizing and modeling parameterized rules.....	193
<b>Chapter 9: Writing Rules to access external data.....</b>	<b>195</b>
A Scope refresher.....	196
Validation of database properties.....	197
Enabling Database Access for Rules using root-level Entities.....	198
Testing the Rulesheet with Database Access disabled .....	199
Testing the Rulesheet with Database Access enabled.....	200
Optimizing Aggregations that Extend to Database.....	205
Precondition and Filters as query filters.....	206
Filter Query qualification criteria.....	207
Operators supported in Query Filters.....	207
Using multiple filters in Filter Queries.....	208
Test yourself - questions – Writing rules to access external data.....	209
<b>Chapter 10: Logical analysis and optimization.....</b>	<b>211</b>
Testing, analysis, and optimization.....	211
Scenario testing.....	212
Rulesheet analysis & optimization.....	212
Traditional means of analyzing logic.....	213
Flowcharts.....	214
Test databases.....	216
Using Corticon Studio to validate rulesheets.....	219
Expanding rules.....	219
The conflict checker.....	221
The completeness checker.....	223
Automatically Determining the Complete Values Set .....	224
Automatic Compression of the New Columns .....	224
Limitations of the Completeness Checker.....	225
Renumbering Rules .....	226
Letting the expansion tool work for you: tabular rules.....	227
Memory management.....	229
Logical loop detection.....	229
Optimizing rulesheets.....	230
The compress tool.....	230
Producing characteristic Rulesheet patterns.....	232
Compression creates sub-rule redundancy.....	234
Effect of compression on Corticon Server performance.....	235
Test yourself - questions – logical analysis and optimization.....	235
<b>Chapter 11: Ruleflow versioning &amp; effective dating .....</b>	<b>239</b>
Setting a Ruleflow version.....	240

---

Major and minor versions.....	240
Setting effective and expiration dates.....	241
Test yourself - questions – ruleflow versioning & effective dating.....	241
<b>Chapter 12: Localizing Corticon Studio .....</b>	<b>243</b>
Localizing the Vocabulary.....	243
Localizing the Rulesheet.....	246
<b>Chapter 13: Working with rules in natural language.....</b>	<b>247</b>
<b>Chapter 14: The Corticon Studio reporting framework.....</b>	<b>249</b>
How Corticon creates reports.....	249
Customizing the XSLT stylesheets.....	250
<b>Chapter 15: Troubleshooting Rulesheets and Ruleflows.....</b>	<b>251</b>
Where did the problem occur?.....	252
Using Corticon Studio to reproduce the behavior.....	252
Running a Ruletest in Corticon Studio .....	252
Analyzing Ruletest results.....	255
Tracing rule execution.....	256
Identifying the breakpoint.....	256
At the breakpoint.....	257
No results.....	258
No partial rule firing.....	258
Initializing null attributes.....	258
Incorrect results in Studio.....	259
Troubleshooting Corticon Server problems.....	259
Test yourself - questions – troubleshooting rulesheets and ruleflows.....	264
<b>Appendix A: Standard boolean constructions.....</b>	<b>267</b>
AND.....	267
NAND.....	269
OR.....	270
XOR.....	270
NOR.....	271
XNOR.....	272
<b>Appendix B: Building a Vocabulary based on Savvion Dataslots.....</b>	<b>273</b>
Generating the Vocabulary file.....	273
Dataslot to Vocabulary Mapping.....	276

- [Overview of Progress Corticon](#)

## Progress Corticon documentation

The following documentation, as well as a *What's New in Corticon* document, is included with this Progress Corticon release:

Corticon Tutorials	
<i>Corticon Studio Tutorial: Basic Rule Modeling</i>	Introduces modeling, analyzing, and testing rules and decisions in Corticon Studio. Recommended for evaluators and users getting started. <i>See also the PowerPoint-as-PDF version of this document that is accessed from the Studio for Analysts' <b>Help</b> menu.</i>
<i>Corticon Studio Tutorial: Advanced Rule Modeling</i>	Provides a deeper look into Corticon Studio's capabilities by defining and testing vocabularies, scope, collections, messages, filters, conditions, transient data, and calculations in multiple rulesheets that are assembled into a Ruleflow. <i>See also the PowerPoint-as-PDF version of this document that is accessed from the Studio for Analysts' <b>Help</b> menu.</i>
<i>Corticon Tutorial: Using Enterprise Data Connector (EDC)</i>	Introduces Corticon's direct database access with a detailed walkthrough from development in Studio to deployment on Server. Uses Microsoft SQL Server to demonstrate database read-only and read-update functions.

<b>Corticon Studio Documentation: Defining and Modeling Business Rules</b>	
<i>Corticon Studio: Installation Guide</i>	Step-by-step procedures for installing Corticon Studio and Corticon Studio for Analysts on computers running Microsoft Windows. Also shows how use other supported Eclipse installations for integrated development. Shows how to enable internationalization on Windows.
<i>Corticon Studio: Rule Modeling Guide</i>	Presents the concepts and purposes the Corticon Vocabulary, then shows how to work with it in Rulesheets by using scope, filters, conditions, collections, and calculations. Discusses chaining, looping, dependencies, filters and preconditions in rules. Presents the Enterprise Data Connector from a rules viewpoint, and then shows how database queries work. Provides information on versioning, natural language, reporting, and localizing. Provides troubleshooting and many <i>Test Yourself</i> exercises.
<i>Corticon Studio: Quick Reference Guide</i>	Reference guide to the Corticon Studio user interface and its mechanics, including descriptions of all menu options, buttons, and actions.
<i>Corticon Studio: Rule Language Guide</i>	Reference information for all operators available in the Corticon Studio Vocabulary. A Rulesheet example is provided for many of the operators. Includes special syntax issues, handling arithmetic and character precedence issues.
<i>Corticon Studio: Extensions Guide</i>	Detailed technical information about the Corticon extension framework for extended operators and service call-outs. Describes several types of operator extensions, and how to create a custom extension plug-in.
<b>Corticon Server Documentation: Deploying Rules as Decision Services</b>	
<i>Corticon Server: Deploying Web Services with Java</i>	Details installing the Corticon Server as a Web Services Server, and then deploying and exposing Decision Services as Web Services on Tomcat and other Java-based servers. Presents the features and functions of the browser-based Server Console.
<i>Corticon Server: Deploying Web Services with .NET</i>	Details installing the Corticon Server as a Web Services Server, and then deploying and exposing decisions as Web Services with .NET. Provides installation and configuration information for the .NET Framework and Internet Information Services (IIS) on various supported Windows platforms.
<i>Corticon Server: Integration &amp; Deployment Guide</i>	An in-depth, technical description of Corticon Server deployment methods, including preparation and deployment of Decision Services and Service Contracts through the Deployment Console tool. Discusses relational database concepts and implementation of the Enterprise Data Connector. Goes deep into the server to discuss state, persistence, and invocations by version or effective date. Includes samples, server monitoring techniques, and recommendations for performance tuning.

# Overview of Progress Corticon

Progress® Corticon® is the Business Rules Management System with the patented "no-coding" rules engine that automates sophisticated decision processes.

## Progress Corticon products

Progress Corticon distinguishes its development toolsets from its server deployment environments.

- **Corticon Studios** are the Windows-based development environment for creating and testing business rules:
  - **Corticon Studio for Analysts.** is a standalone application, a lightweight installation that focuses exclusively on Corticon.
  - **Corticon Studio** is the *Corticon Designer* perspective in the **Progress Developer Studio** (PDS), an industry-standard Eclipse and Java development environment. The PDS enables development of applications integrated with other products, such as Progress OpenEdge.

The functionality of the two Studios is virtually identical, and the documentation is appropriate to either product. Documentation of features that are only in the *Corticon Designer* (such as on integrated application development and Java compilation) will note that requirement. Refer to the *Corticon Studio: Installation Guide* to access, prepare, and install each of the Corticon Studio packages.

**Studio Licensing** - Corticon embeds a time-delimited evaluation license that enables development of both rule modeling and Enterprise Data Connector (EDC) projects, as well as testing of the projects in an embedded Axis test server. You must obtain studio development licenses from your Progress representative.

- **Corticon Servers** implement web services for business rules defined in Corticon Studios:
  - **Corticon Server for deploying web services with Java** is supported on various application servers, and client web browsers. After installation on a supported Windows platform, that server installation's deployment artifacts can be redeployed on various UNIX and Linux web service platforms as Corticon Decision Services. The guide *Corticon Server: Deploying web services with Java* provides details on the full set of platforms and web service software that it supports, as well as installation instructions in a tutorial format for typical usage.
  - **Corticon Server for deploying web services with .NET** facilitates deployment of Corticon Decision Services on Windows .NET Framework and Microsoft Internet Information Services (IIS). The guide *Corticon Server: Deploying web services with .NET* provides details on the platforms and web service software that it supports, as well as installation instructions in a tutorial format for typical usage.

**Server Licensing** - Corticon embeds a time-delimited evaluation license that enables evaluation and testing of rule modeling projects on supported platform configurations. You must obtain server deployment licenses and server licenses that enable the Enterprise Data Connector (EDC) from your Progress representative.

## Building the Vocabulary

---

This section describes the concepts and purposes of a Corticon Vocabulary. You see how to build a Vocabulary from general business concepts and relationships.

For details, see the following topics:

- [What is a Vocabulary?](#)
- [Designing the Vocabulary](#)
- [Modeling the Vocabulary in Corticon Studio](#)
- [Custom Data Types](#)
- [Domains](#)
- [Support for inheritance](#)
- [Test yourself - questions – building the vocabulary](#)

## What is a Vocabulary?

Depending on your point of view, a Vocabulary represents different things and serves different purposes. For the rule modeler, the Vocabulary provides the basic elements of the rule language – the building blocks with which business rules are implemented in Corticon. For a systems analyst or programmer, a vocabulary is an abstracted version of a data model that contains the objects used in those business rules implemented in Corticon.

A vocabulary serves the following purposes:

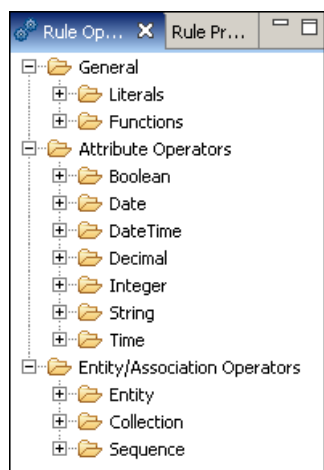

- Provides terms that represent business "things". Throughout the product documentation, we will refer to these things as *entities*, and properties or characteristics of these things as *attributes*. Entities and their attributes in underlying data sources (such as tables in a relational database or fields in a user interface) can be represented in the Vocabulary.
- Provides terms that are used to hold temporary or *transient* values within Corticon (such as the outcome of intermediate derivations). These entities and attributes usually have a business meaning or context, but do not need to be saved (which we will also refer to as *persisting*) in a database, or communicated to other applications external to Corticon. An example of this might be the following two simple computational rules:

1. `itemSubTotal` is equal to the product of `itemCount` and `itemPrice`
2. `orderTotal` is equal to the sum of all `itemSubTotals`

In these two rules, `itemSubTotal` is the intermediate or transient term. We may never use `itemSubTotal` by itself; instead, we may only create it for purposes of subsequent derivations, as in the calculation of `orderTotal` in rule #2. Since a transient attribute may be the result of a very complicated rule, it may be convenient to create a Vocabulary term for it and use it whenever rewriting the complex rule would be awkward or unclear. Also see [Extended Transients](#), in the Vocabulary.

- Provides a federated data model that consolidates entities and attributes from various enterprise data resources. This is important because a company's data may be stored in many different databases in many different physical locations. Corticon believes that rule modelers need not be concerned with where data is, only how it is used in the context of building and evaluating business rules. The decision management system should ensure that proper links are maintained between the Vocabulary and the underlying data. We often refer to this concept as *abstraction* – the complexities of an enterprise's data storage and retrieval systems have been hidden so that only the aspects relevant to rule writing are presented to the rule modeler.
- Provides a built-in library of *literal* terms and operators that can be applied to entities or attributes in the Vocabulary. This part of the Vocabulary, the "lower half" of the **Vocabulary** window shown in the following figure, is called the "Operator Vocabulary" because it provides many of the verbs (the "operators") needed in our business rules. Many standard operators such as the mathematical functions { +, -, \*, / } and comparator functions { <, >, = } as well as more specialized functions are contained within this portion of the Vocabulary. See the *Rule Language Guide* for descriptions and examples of all operators available, as well as detailed instructions for extending the library.

**Figure 1: Operator Vocabulary**

- Defines a schema that supplies the contract for sending data to and from a Corticon Decision Service ( Rulesheets deployed in production). Since XML messaging is used to carry data to and from the rules for evaluation, data must be organized in a pre-defined structure that can be understood and processed by the rules. An XML schema that accomplishes this purpose can be automatically generated directly from the Vocabulary. This schema is called a Vocabulary-Level service contract and details can be found in the *Server Integration & Deployment Guide*.

### Scope

An important point about a Vocabulary: there does not need to be a one-to-one correlation between terms in the Vocabulary and terms in the enterprise data model. In other words, there may be terms in the data model that are not included in or referenced by rules – such terms need not be included in the Vocabulary. Conversely, the Vocabulary may include terms (such as extended transient attributes) that are used only in rules – these terms need not be present in the data model. Two guiding principles:

- If the rule modeler wants to use a particular term in a business rule, then that term must be part of the Vocabulary. This can include terms that exist only within the Vocabulary – these are the transient attributes introduced above.
- If a rule produces a value that must be retained, persisted, or otherwise saved in a database (or other means external to the rules), then that Vocabulary term must also be present in the enterprise data model. There are many methods for linking or mapping these Vocabulary terms with corresponding terms in the data model, but a discussion of these methods is technical in nature and is not included in this manual.

There are two basic starting points for creating a Vocabulary: starting from an existing data model or starting from scratch. We will start by examining the latter since it is typically more challenging.

## Starting from scratch

### Investigation

The first step in creating a Vocabulary from scratch is to collect information about the specifics of the business problem you are trying to solve. This usually includes research into the more general business context in which the problem exists. Various resources may be available to you to help in this process, including:

- **Interviews** – the business users and subject matter experts themselves are often the best source of information about how business is conducted today. They may not know how the process is *supposed* to work, or how it *could* work, but in general, no one knows better how a business process or task is performed today than those who are actually performing it.
- **Company policies and procedures** – when they exist, written policies and procedures can be an excellent source of information about how a process is *supposed* to work and the rules that govern the process. Understanding the gaps between what is supposed to happen and what is actually happening can provide valuable insight into the root problems.
- **Existing systems & databases** – systems are usually created to address specific business needs, but needs often change faster than systems can keep up. Understanding what the systems were designed to do versus how they are actually being used often provides clues about the core problems. Also, business logic contained in these legacy systems often captures business policies and procedures (i.e., the business rules) that are not recorded anywhere else.
- **Forms and reports** – even in heavily automated businesses, forms and reports are often used extensively. These documents can be very useful for understanding the details of a business

process. Reports also illustrate the expected output from a system, and highlight the information users require.

Analyze the chosen scenario and/or existing business rules in order to identify the relevant terms and the relationships between these terms. We refer to statements expressing the relevant terms and relationships as "facts" and recommend developing a "Fact Model" to more clearly illustrate how they fit together. We will use a simple example to show the creation of a Fact Model and its subsequent development into a Vocabulary for use in Corticon Studio.

## Designing the Vocabulary

### Example

An air cargo company has a manual process for generating flight plans. These flight plans assign cargo shipments to specific aircraft. Each flight plan is assigned a flight number. The cargo company owns a small fleet of three airplanes -- two Boeing 747s and one McDonnell-Douglas DC-10 freighter. Each airplane type has a maximum cargo weight and volume that cannot be exceeded. Each aircraft also has a tail number which serves to identify it. A cargo shipment has characteristics like weight, volume and a manifest number to identify it.

Now let's assume the company wants to build a system that automatically checks flight plans to ensure no scheduling rules or guidelines are violated. One of the many business rules that need to be checked by this system is:

1. An aircraft must not carry a cargo shipment that exceeds its maximum cargo weight.

## Step 1 – Identify the Terms

We identify the terms (entities and attributes) for our Vocabulary by circling or highlighting those nouns that are used in the business rules we seek to automate. The previous example is reproduced below:

An air cargo company has a manual process for generating flight plans. These flight plans assign cargo shipments to specific aircraft. Each flight plan is assigned a flight number. The cargo company owns a small fleet of three airplanes, 2 Boeing 747s and 1 McDonnell-Douglas DC-10 freighter. Each airplane type has a maximum cargo weight and volume that cannot be exceeded. Each aircraft also has a tail number which serves to identify it. A cargo shipment has characteristics like weight, volume, packaging method, and a manifest number to identify it.

## Step 2 – Separating the Generic Terms from the Specific

Why did we only circle the "aircraft" term above and not the names of the aircraft in the fleet? It is because 747 and DC-10 are *specific* types of the *generic* term aircraft. The *type* of aircraft can be said to be an attribute of the generic aircraft entity. Along these same lines, we also know from the example that several cargo shipments and flight plans can exist. Like the specific aircraft, these are *instances* of their respective generic terms. For the Vocabulary, we are only interested in identifying the generic (and therefore reusable) terms. But ultimately, we also will need a way to identify specific cargo shipments and flight plans from within the set of all cargo shipments and flight plans – assigning *values* to attributes of a generic entity will accomplish this goal, as we will see later.

## Step 3 – Assembling and Relating the Terms

None of the terms we have circled exists in isolation – they all relate to each other in one or more ways. Understanding these relationships is the next step in Vocabulary construction. We begin by simply stating facts observed or inferred from the example:

- An aircraft *carries* a cargo shipment.
- A flight plan *schedules* cargo for shipment *on* an aircraft.
- A cargo shipment *has* a weight.
- A cargo shipment *has* a manifest number.
- An aircraft *has* a tail number.
- An aircraft *has* a maximum cargo weight.
- A 747 *is* a type of aircraft.

And so on...

Notice that some of these facts describe how one term relates to another term; for example, an aircraft *carries* a cargo shipment. This usually provides a clue that the terms in question, aircraft and cargo shipment, are entities and are two of the primary terms we are interested in identifying.

Also notice that some facts describe what Business Rule Solutions, LLC (BRS) calls "has a" relationships; for example, an aircraft "has a" tail number, or a cargo "has a" weight. This type of relationship usually identifies the subject (aircraft) as an entity and the object (tail number) as an attribute of that entity. By continuing the analysis, we discover that the problem reduces to a Vocabulary containing 3 main entities, each with its own set of attributes:

**Entity:** aircraft

**Attributes:** aircraft type, max cargo weight, max cargo volume, tail number

**Entity:** cargo shipment

**Attributes:** weight, volume, manifest number, packaging

**Entity:** flight plan

**Attributes:** flight number

## Step 4 – Diagramming the Vocabulary

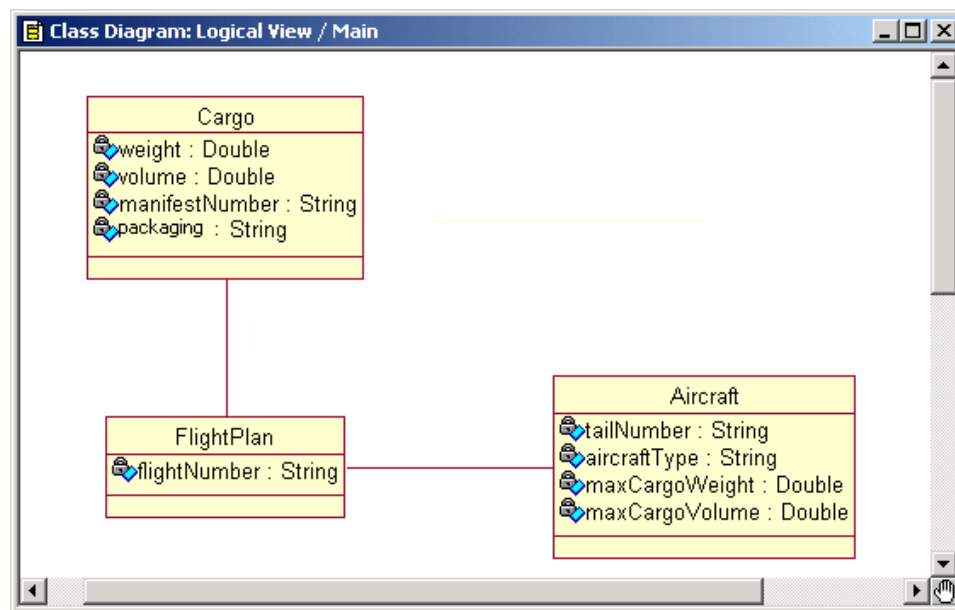

Using this breakdown, we can sketch a simple Fact Model that illustrates the entities and their relationships, or *associations*. In our Fact Model, we will represent entities as rectangular boxes, associations between entities as straight lines connecting the entity boxes, and entity-to-attribute relationships as a diagonal line from the associated entity. The resulting Fact Model appears below in the following model:

**Figure 2: Fact Model**

The UML Class diagram contains the same type of information, and may be more familiar to you:

**Figure 3: UML Class Diagram**

It is not a requirement to construct diagrams or models of the Vocabulary before building it in Corticon Studio. But it can be very helpful in organizing and conceptualizing the structures and relationships, especially for very large and complex Vocabularies. The BRS Fact Model and UML Class Diagram are appropriate because they remain sufficiently abstracted from lower-level data models which contain information not typically required in a Vocabulary.

## Modeling the Vocabulary in Corticon Studio

Our next step is to transform the diagram into our actual Vocabulary. This can be done directly in Corticon Studio using the built-in **Vocabulary Editor** feature.

Refer to the "Vocabulary" chapter of the *Quick Reference Guide* for complete details on building a Vocabulary inside Studio.

The following considerations apply to this transformation process:

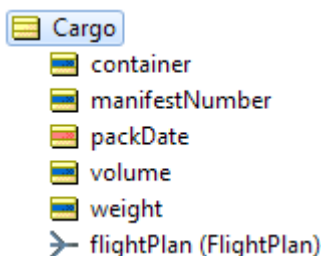

- The same naming conventions for entities and attributes used in the Fact Model will also be used in the Vocabulary.
- All attributes in our Vocabulary must have a data type specified. These may be any of the following common data types: **String**, **Boolean**, **DateTime**, **Date**, **Time**, **Integer** or **Decimal**.
- Attributes are classified according to the method by which their values are assigned. They are either:
  - **Base** -- Values are obtained directly from input data or request message, or
  - **Extended Transient** -- Created, derived, or assigned by rules in Studio.

---

### Note:

Extended transient attributes carry or hold values while rules are executing within a single Rulesheet. Since XML messages returned by a Decision Service do not contain extended transient attributes, these attributes and their values cannot be used by external components or applications. If an attribute value is used by an external application or component, it must be a base attribute.

To show the rule modeler which attributes are base and which are extended transient, Corticon Studio adds an orange bar to extended transient attributes, as shown here for `packDate`:

XML response messages created by Corticon Server will not contain the `packDate` attribute.

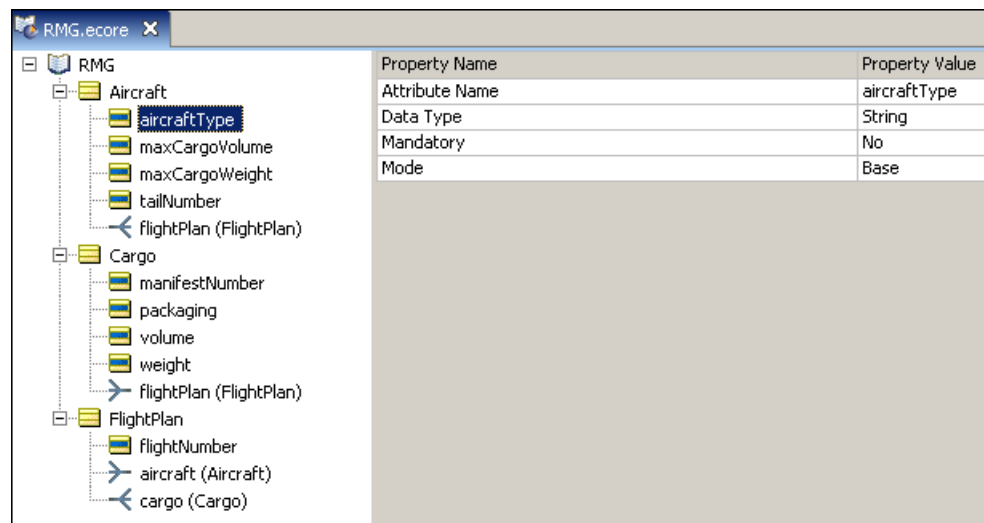

---

It is a good idea to use a naming convention that distinguishes transient attributes from base. For example, you could start an extended transient attribute's name with `et_` such as `et_packDate`. We caution against modifying the names of terms so that they are cryptic. The intent is to express them in a language accessible to business users, as well as developers.

- Associations between entities have role names that are assigned when building the associations in the UML class diagram or Vocabulary Editor. Default role names simply duplicate the entity name with the first letter in lowercase. For example, the association between the `Cargo` and `FlightPlan` entities would have a role name of "flightPlan" as seen by the `Cargo` entity, and "cargo" as seen by the `FlightPlan` entity. [Roles](#) are useful in clarifying context in a rule – a topic covered in more detail within the [Scope](#) chapter.
- Associations between entities can be directional (one-way) or bi-directional (two-way). If the association between `FlightPlan` and `Aircraft` were directional (with `FlightPlan` as the "source" entity and `Aircraft` as "target"), we would only be able to write rules that traverse *from* `FlightPlan` *to* `Aircraft`, but not the other way. This means that a rule may use the Vocabulary term `flightPlan.aircraft.tailNumber` but may not use `aircraft.flightPlan.flightNumber`. Bi-directional associations allow us to traverse the association in either direction, which clearly allows us more flexibility in writing rules. Therefore, it is strongly recommended that all associations be bi-directional whenever possible. New associations are bi-directional by default.
- Associations also have cardinality, which indicates how many instances of a given entity may be associated with another entity. For example, in our air cargo scenario, each instance of `FlightPlan` will be associated with only one instance of `Aircraft`, so we can say that there is a "one-to-one" relationship between `FlightPlan` and `Aircraft`. The practice of specifying cardinality in the Vocabulary deviates from the UML Class modeling technique because the act of assigning cardinality can be viewed as defining a constraint-type rule. For example, "a `flightPlan` schedules exactly one `aircraft` and one `cargo` shipment" is a constraint-type business rule that can be implemented in a Corticon Studio as well as "embedded" in the associations within a Vocabulary. In practice, however, it may often be more convenient to embed these constraints in the Vocabulary, especially if they are unlikely to change in the future.
- Another consideration when creating a Vocabulary is whether derived attributes must be saved (or persisted) external to Corticon Studio, for example, in a database. It is important to note that while the structure of your Vocabulary may closely match your data model (often persisted in a relational database), the Vocabulary is *not required* to include all of the database entities/tables or attributes/columns, especially if they will not be used for writing rules. Conversely, our Vocabulary may contain attributes that are used only as transient variables in rules and that do not correspond to fields in an external database.
- Finally, the Vocabulary must contain all of the entities and attributes needed to build rules in Corticon Studio that reproduce the decision points of the business process being automated. This will most likely be an iterative process, with multiple Vocabulary changes being made as the rules are built, refined, and tested. It is very common to discover, while building rules, that

the Vocabulary does not contain necessary terms. But the flexibility of Corticon Studio permits the rule developer to update or modify the Vocabulary immediately, without programming.

**Figure 4: Vocabulary Window in Corticon Studio**

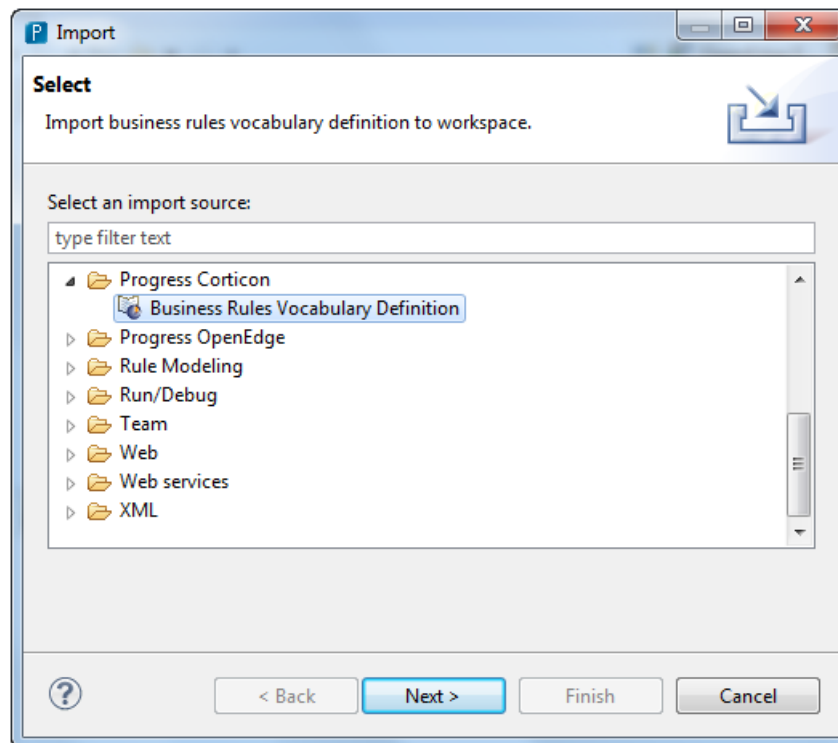

**Note:** In this figure, Corticon Studio is shown in **Rule Modeling** mode. If in **Integration Deployment** mode, the **Property Name** column will contain additional rows. For more information on Integration Deployment mode, see the *Corticon Server: Integration & Deployment Guide*.

## Importing an OpenEdge Business Rules Vocabulary Definition (BRVD) file

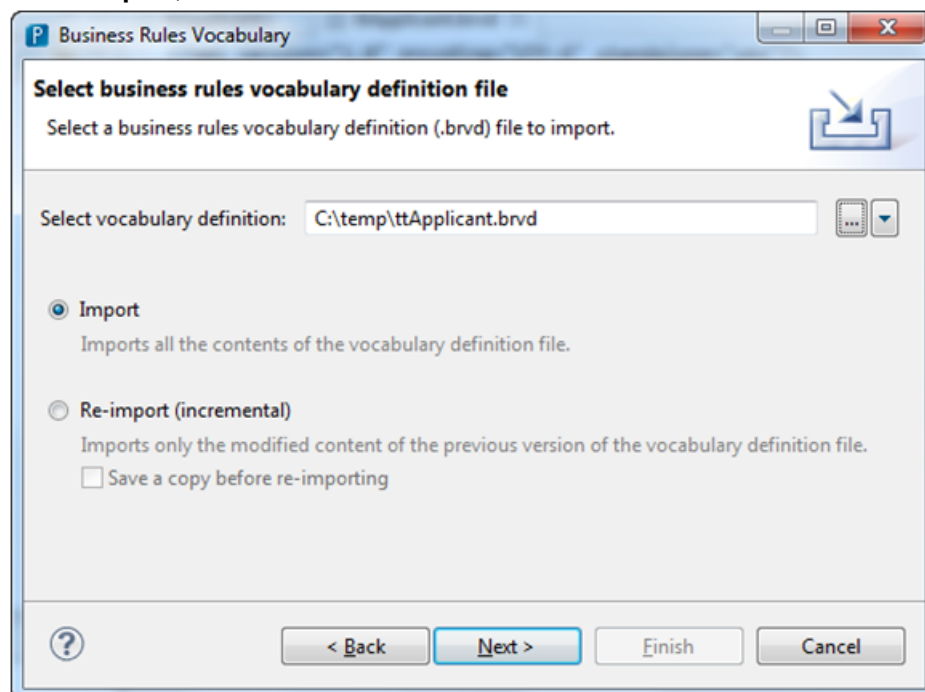

OpenEdge developers can use Corticon for their business rules, using Progress Developer Studio to integrate their ABL projects with Corticon Decision Services. A schema exported from Progress OpenEdge can be imported and used as the basis for Vocabulary entities and attributes in Corticon Studio.

To import a Vocabulary definition created in OpenEdge into the Corticon perspective:

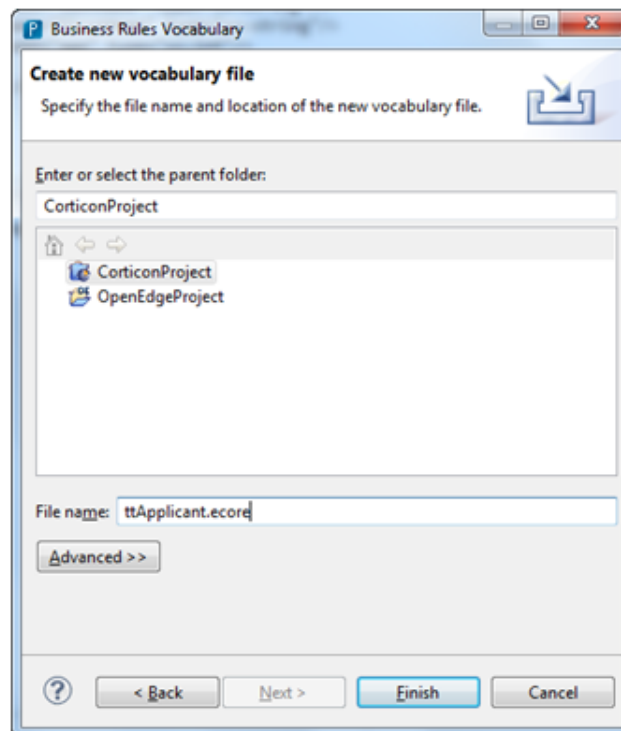

1. In the integrated OpenEdge/Corticon Eclipse development environment, choose the menu command **Window > Open Perspective > Corticon Designer**.
2. Choose the menu command **File > New > Rule Project**, name the project -- in this example, *CorticonProject* -- and then click **Finish**.
3. Choose the menu command **File > New > Progress Corticon > Rule Project**.
4. In the **New Corticon Project** wizard, specify the name and location of the project.
5. Optionally, add the project to working sets and selected project references.
6. Click **Finish**. The new project is created and displayed in the **Project Explorer** view.
7. Click on the project name, and then choose the menu command **File > Import > Import**.
8. In the **Import** dialog, expand **Progress Corticon**, and then click on **Business Rules Vocabulary Definition**, as shown:

9. In the **Business Rules Vocabulary** dialog, locate the .brvd file -- in this example, ttApplicant.brvd, that was staged in the c:\temp folder -- that was created in OpenEdge.
10. Select **Import**, as shown:

11. Click **Next**.
12. Select the **CorticonProject**, and then enter the Vocabulary **File name** -- in this example, ttApplicant.ecore, as shown. (The name must have the ..ecore extension.)

13. Click **Finish**.

14. Double-click on the `.ecore` file name in the Project Explorer to open it in the Corticon Vocabulary editor. The example looks like this:

15. Review the Vocabulary to ensure that it represents the exported data correctly.

The import processing of the OpenEdge BRVD file into a Corticon Vocabulary is complete.

You can now create and test Rulesheets and Ruleflows, and then publish a Decision Service to Corticon Server (such as the one that runs in an OpenEdge Web Server).

## Locking and unlocking Corticon Vocabularies

There are advantages to locked and unlocked Vocabularies:

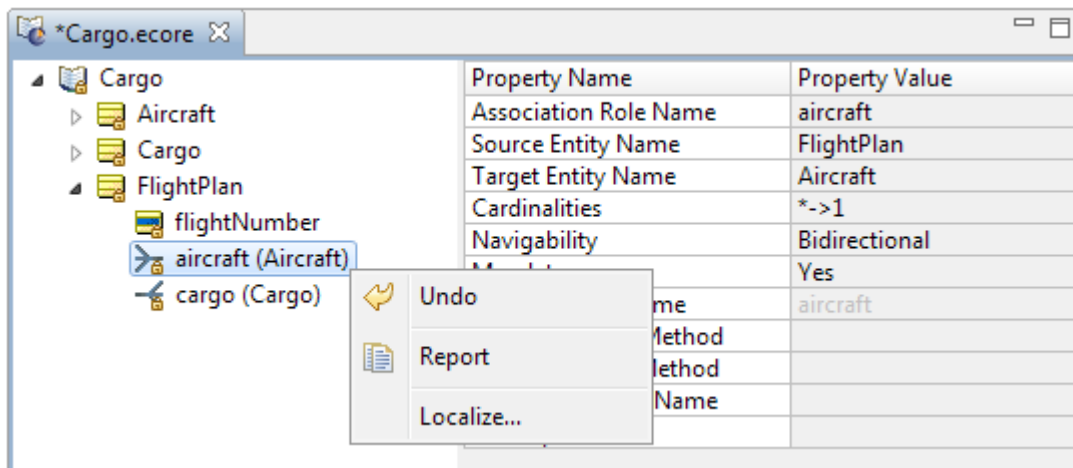

- When your rule development has many Rulesheets and Ruletests, you might want to add a measure of control over Vocabulary changes. Locking the Vocabulary prevents you from accidentally changing an entity or attribute, thereby invalidating rules and calls from databases.
- When OpenEdge developers use Corticon for their business rules, they use Progress Developer Studio to integrate their ABL projects with Corticon Decision Services. During import of a Business Rules Vocabulary Definition (BRVD) created in Open Edge, a Corticon mechanism flags vocabulary entities, attributes, and associations as read-only. This protection keeps you from accidentally modifying the Vocabulary such that it no longer matches its source in

OpenEdge. If you want to define transient attributes, constraint expressions, or make other modifications to the vocabulary in Corticon you will need to unlock it. When doing so, you need to be sure that your modifications do not make the vocabulary incompatible with its source in OpenEdge.

You can choose to lock a Vocabulary in Studio by selecting the **Set to Read Only** option, as shown:

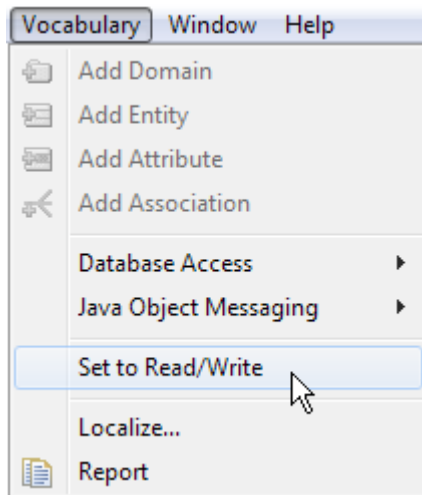

Once locked, all the icons in the Vocabulary display a padlock symbol.

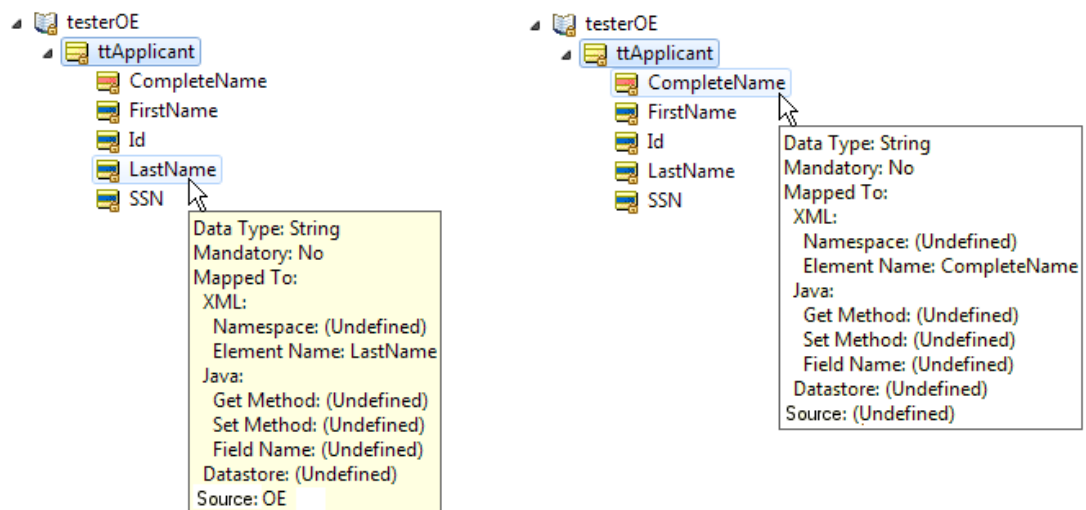

In a locked Vocabulary, all functions in the Vocabulary editor are display-only, including Custom Data Types and Database Access. **Undo** (and **Redo**) options will toggle the mode until the Vocabulary file is saved.

A locked Vocabulary can be unlocked by selecting the **Set to Read/Write** option.

**Note:** In Vocabularies created through BRVD import, changes that you make when unlocked and then locked again, continue to reflect the OE origin of BRVD imported attributes and entities.

You should never rename attributes or entities that are bound to OpenEdge or EDC resources as they would likely cause data synchronization problems.

## Applying an updated BRVD to a Vocabulary

If you make changes to your OpenEdge application, you might need to regenerate the BRVD file, and then re-import it into Corticon to update your Vocabulary.

A re-imported BRVD file impacts any changes you might have made if you set the imported Vocabulary into Read/Write mode. While you cannot change the Vocabulary when it is in Read Only mode, the re-import actions will proceed on a locked or unlocked Vocabulary.

**Note:** A re-import of a BRVD file changes the current Vocabulary. It is a good practice to choose **Save a copy before re-importing** in the import dialog to backup the existing Vocabulary before applying changes to it, especially if you entered Read/Write mode and made changes.

Before the re-import action is applied, a dialog displays the entities, attributes, and associations in the Vocabulary and how they will be impacted.

The status and intended actions on Vocabulary entities, attributes, and associations during a re-import can be the following:

- **Match**- No action if the imported element and the existing element are identical in the following ways:
  - Entity: Same name and same origination (BRVD import or user-defined action)
  - Attribute: Same name, same datatype, and same origination (BRVD import or user-defined action)
  - Association: Same name, same target entity, and same cardinality
- **UserDefined** - No action if the existing element was created in Corticon.
- **Add** - The imported element is entered into the Vocabulary and marked as originating from the BRVD as follows:
  - Entity: The entity name in the BRVD does not match an existing entity in the Vocabulary
  - Attribute: The attribute name in the BRVD does not match an existing attribute in the corresponding entity in the Vocabulary.
  - Association: The association name in the BRVD does not match an existing association in the Vocabulary
- **Remove** - Deletes the existing element if it was previously created from a BRVD element, but is not in the import file.
- **Remove/Re-add** - Removes the existing element and then recreates it from its definition in the import file, under the following conditions:
  - Attribute: Same name but the datatype is different. (When the datatype is an enumerated list or constraint expression, if that custom data type has the same base data type as the imported attribute in the BRVD, it is a Match.)
  - Association: Same name but with a different Target Entity.

---

**Note:** The Remove/Re-Add action does not apply to an Entity that originated from a BRVD. A re-import can either Add or Remove a BRVD originated entity.

---

- **Merge** - Revises an existing element marked as created locally that is now a BRVD element in the import file. The existing element will transform to be defined as an imported element (originated from BRVD) and marked as Merge, as follows:
  - Entity: Same name, but created in the Vocabulary editor.
  - Attribute: Same name, same datatype, but created in the Vocabulary editor. If the existing element was defined as extended transient mode, it is changed to base mode.
  - Association: Same name, same target entity, but different cardinality or created in the Vocabulary editor.

The dialog lets you choose to **Copy to Clipboard** to retain the action list as this information will not be available once you proceed to apply the re-import actions.

---

**Note:** If you choose to **Cancel** at this point, nothing was changed.

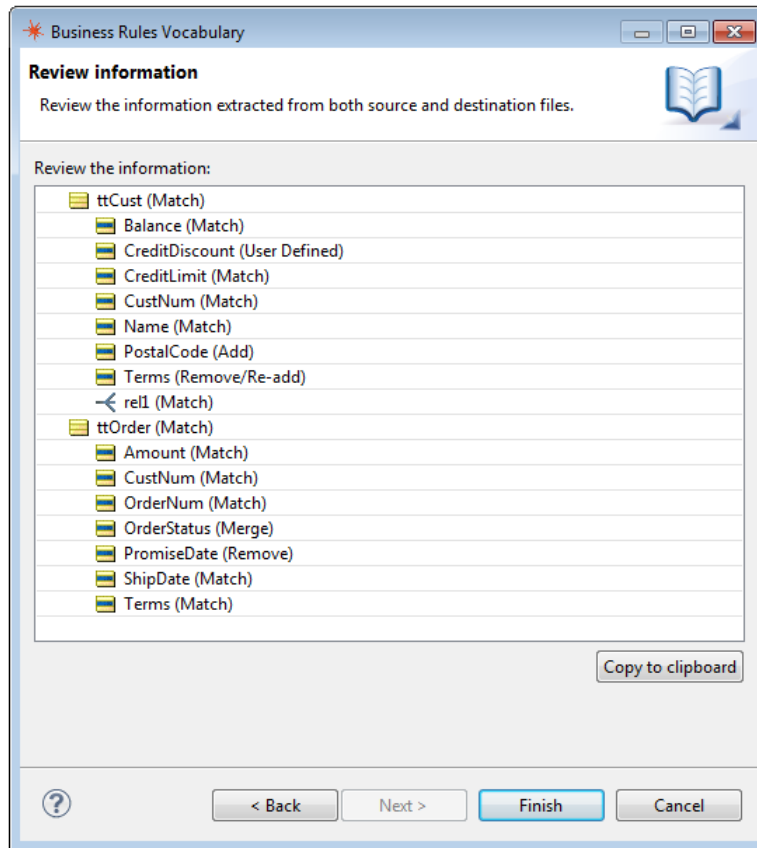

---

See the Progress OpenEdge documentation for details about a complete end-to-end workflow involved in an integrated OpenEdge Business Rules environment.

## Example

The following figure shows how some BRVD changes to attributes are displayed for review:

**Figure 5: Review information before re-import is applied.**

The revised BRVD file is being re-imported into a Vocabulary previously created from a BRVD. The following attribute changes are shown in the Review Information dialog above:

- **Match** – Unchanged attributes that originated in OpenEdge.
- **User Defined** – Added `CreditDiscount` only in Corticon.
- **Add** – `Postal code` added in OpenEdge and then added into the latest BRVD file.
- **Remove/Re-add** – Changed `Terms` to an `integer` only in Corticon, but it is still a `decimal` in OpenEdge and the BRVD. After this action, `Terms` is a `decimal`.
- **Merge** – Added `OrderStatus` to Corticon while awaiting BRVD change from OpenEdge. The new BRVD has `OrderStatus` so it is a merge
- **Remove** - Dropped the `Promise date` in OpenEdge from the latest BRVD file.

## Custom Data Types

Corticon uses seven basic data types: Boolean, Decimal, Integer, String, DateTime, Date, and Time. An attribute must use one of these types. Yet you also have the option of creating custom data types that "extend" any one of these basic seven.

You define and maintain Custom Data Types in a Vocabulary by selecting the Vocabulary name in the tree view.

### Data Type Name

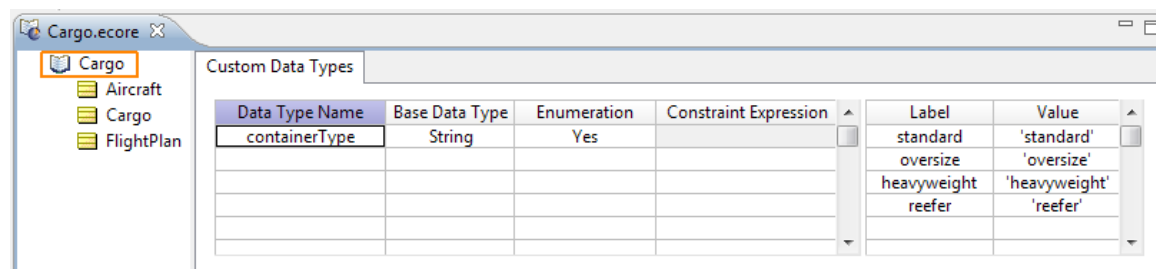

When defining a custom data type, you must give it a name. The name must comply with standard entity naming conventions (see the *Quick Reference Guide* for details) and must not overlap (match) any of the base data types, any other custom data type names, or the names of any Vocabulary entities.

### Base Data Type

The selection in this field determines which base data type the custom data type extends.

We already used this feature in the custom data type `containerType`, a `String`, in the *Basic Tutorial*. It lists its labels and values.

**Figure 6: Vocabulary Editor Showing the Custom Data Type `containerType`**

### Enumeration Or Constraint Expression?

**Enumeration** - When the **Enumeration** for a Custom Data Type is set to `Yes`, as shown above, the **Constraint Expression** field is disabled, and the **Label** and **Value** columns are enabled.

**Constraint Expression** - When the **Enumeration** for a Custom Data Type is set to `No`, the **Constraint Expression** field is enabled and the **Label** and **Value** columns are disabled.

The following sections explore each of these features.

## Constraint Expressions

When you want to prompt Rulesheet and Ruletest designers to use a specific range values for an attribute, a constraint expression will validate entries when the associated Ruletest runs.

Constraint expressions are optional for non-enumerated Custom Data Types, but if none are used then the Custom Data Type probably isn't necessary because it reduces to a base attribute with a custom name.

All **Constraint Expressions** must be `Boolean` expressions, in other words they must return or resolve to a Boolean value of `true` or `false`. The supported syntax is the same as Filter expressions with the following rules and exceptions:

- Use the `value` to represent the Custom Data Type value.
- Logical connectors such as `and` and `or` are supported
- Parentheses may be used to form more complex expressions
- The expression may include references to Base and Extended Operators which are compatible with the Base Data Type chosen.
- No Collection operators may be referenced in the expression.
- There should be NO references to `null`. This is because `null` represents a lack of value and is not a real value. The Constraint Expression is intended to constrain the value space of the data type and expressions such as `attribute expression <> null` do not belong in it. An attribute that must not have a null value can be so designated by selecting `Yes` in its **Mandatory** property value.

The following are typical Constraint Expressions:

Constraint Expression	Meaning
<code>value &gt; 5</code>	Integer values greater than 5
<code>value &gt;= 10.2</code>	Decimal values greater than or equal to 10.2
<code>value in (1.1..9.9]</code>	Decimal values between 1.1 (exclusive) and 9.9 (inclusive)
<code>value in ['1/1/2000 12:30:00 PM'..'1/2/2000 11:00:00 AM']</code>	DateTime values between '1/1/2000 12:30:00 PM' (inclusive) and '1/2/2000 11:00:00 AM' (exclusive)
<code>value in ['1:00:00 PM'..'2:00:00 PM']</code>	Time values between '1:00:00 PM' (inclusive) and '2:00:00 PM' (inclusive)
<code>value.size &gt;= 6 and (value.indexOf(1) &gt; 0 or value.indexOf(2) &gt; 0)</code>	String values of minimum 6 characters in length that contain at least a 1 or 2

## Using non-enumerated Custom Data Types in Rulesheets and Ruletests

Non-enumerated custom data types use **Constraint Expressions** and do not cause Rulesheet drop-downs to become populated with custom sets. Also, manually entering a cell value that violates the custom data type's **Constraint Expression** is not prohibited in the Rulesheet. For example, in the example below, `weightLimit` is defined as a non-enumerated custom data type with **Base Data Type** of `Integer`.

**Figure 7: Non-enumerated Custom Data Types**

Custom Data Types			
Data Type Name	Base Data Type	Enumeration	Constraint Expression
weightRange	Decimal	No	value < 200000

Then, after assigning it to the Vocabulary attribute `Cargo.weight`, it is used in a Rulesheet Condition row as shown below:

**Figure 8: Using Custom Data Types in a Rulesheet**

Conditions		0	1
a	Cargo.weight		300000
Actions			
Post Message(s)			
A			
Overrides			

Ref	ID	Post	Alias	Text
1		Violation	Cargo	300,000 exceeds the CDT constraint

Notice in *Using Custom Data Types in a Rulesheet* that the 55000 entry violates the **Constraint Expression** of the custom data type assigned to `Cargo.weight`, but *does not turn red or otherwise indicate a problem*. The indication comes when data is entered for the attribute in a Ruletest, as shown below:

**Figure 9: Violating a Custom Data Type's Constraint Expression**

Input	Output
Cargo [1] <ul style="list-style-type: none"> <li>manifestNumber</li> <li>packaging</li> <li>volume</li> <li>weight [300000]</li> </ul>	

Notice that the small yellow warning icon ⚠ indicates a problem in the attribute, entity, and both Ruletest tabs. Such an error is hard to miss! Also, a Warning message will appear in the **Problems** tab (if open and visible) as shown below. If the Problems tab is closed, you can display it by selecting **Window > Show View > Problems** from the **Studio** menubar.

**Figure 10: Violating the Constraint Expression of a Custom Data Type**

A Warning will not prevent you from running the Ruletest. However, an Error, indicated by a small red icon ✖, will prevent the Ruletest execution. You must fix any errors before testing.

## Enumerations

When you want to prompt Rulesheet and Ruletest designers to use a specific list of values, you can specify an explicit list, either maintained directly in the Vocabulary, or retrieved and updated from a database.

### Enumerations defined in the Vocabulary

If your custom data type is a local enumeration, then you need to enter the enumerated values in the **Label** and **Value** columns.

The **Label** column is optional: you enter **Labels** only when you want to provide an easier-to-use or more intuitive set of names for your enumerated values.

The **Value** column is mandatory: you need to enter the enumerations in as many rows of the **Value** column as necessary to complete the enumerated set. Be sure to use normal syntax, so custom data types that extend String, DateTime, Date, or Time base data types must be enclosed in single quote characters.

Here are some examples of enumerated custom data types:

**Figure 11: Custom Data Type, example 1**

Custom Data Types						
Data Type Name	Base Data Type	Enumerati...	Constraint Expression		Label	Value
containerType	String	Yes				2
PrimeNumbers	Integer	Yes				3
USHolidays2015	Date	Yes				5
ShirtSize	Integer	Yes				7
RiskProfile	Integer	Yes				11
DevTeam	String	Yes				13

PrimeNumbers is an Integer-based, enumerated custom data type with Value-only set members.

**Figure 12: Custom Data Type, example 2**

Custom Data Types						
Data Type Name	Base Data Type	Enumerati...	Constraint Expression		Label	Value
containerType	String	Yes			standard	'standard'
PrimeNumbers	Integer	Yes			oversize	'oversize'
USHolidays2015	Date	Yes			heavyweight	'heavyweight'
ShirtSize	Integer	Yes			reefer	'reefer'
RiskProfile	Integer	Yes				
DevTeam	String	Yes				

packingType is a String-based, enumerated custom data type with Label/Value pairs.

**Figure 13: Custom Data Type, example 3**

Custom Data Types						
Data Type Name	Base Data Type	Enumerati...	Constraint Expression		Label	Value
containerType	String	Yes			New_year	'1/1/2015'
PrimeNumbers	Integer	Yes			Independen...	'7/4/2015'
USHolidays2015	Date	Yes			Labor_Day	'9/7/2015'
ShirtSize	Integer	Yes			Thanksgiving	'11/26/2015'
RiskProfile	Integer	Yes			Christmas	'12/25/2015'
DevTeam	String	Yes				

USHolidays2015 is a Date-based, enumerated custom data type with Label/Value pairs.

**Figure 14: Custom Data Type, example 4**

Custom Data Types						
Data Type Name	Base Data Type	Enumerati...	Constraint Expression		Label	Value
containerType	String	Yes			S	1
PrimeNumbers	Integer	Yes			M	2
USHolidays2015	Date	Yes			L	3
ShirtSize	Integer	Yes			XL	4
RiskProfile	Integer	Yes			XXL	5
DevTeam	String	Yes				

ShirtSize is an Integer-based, enumerated custom data type with Label/Value pairs.

**Figure 15: Custom Data Type, example 5**

Custom Data Types						
Data Type Name	Base Data Type	Enumerati...	Constraint Expression		Label	Value
containerType	String	Yes			Low	1
PrimeNumbers	Integer	Yes			Medium	2
USHolidays2015	Date	Yes			High	3
ShirtSize	Integer	Yes			VeryHigh	4
RiskProfile	Integer	Yes				
DevTeam	String	Yes				

RiskProfile is an Integer-based, enumerated custom data type with Label/Value pairs

**Figure 16: Custom Data Type, example 6**

Custom Data Types						
Data Type Name	Base Data Type	Enumerati...	Constraint Expression		Label	Value
containerType	String	Yes				'Dave'
PrimeNumbers	Integer	Yes				'John'
USHolidays2015	Date	Yes				'Jim'
ShirtSize	Integer	Yes				'Prashant'
RiskProfile	Integer	Yes				'Mahesh'
DevTeam	String	Yes				'Kendall'
						'George'
						'Cheryl'
						'Amish'
						'Eric'
						'Marian'

DevTeam is a String-based, enumerated custom data type with Value-only set members.

Use the **Move Up**  or **Move Down**  toolbar icons to change the order of Label/Value rows in the list.

## Enumerations retrieved from a database

If you want your custom data type to get its enumerated labels and values from a database, then you need to define the database table and columns that will be accessed.

This topic covers the significant points of this feature in the context of the Vocabulary.

When you have EDC enabled -- you are in Integration and Deployment mode, and you have a verified connection to a supported database -- the **Custom Data Types** tab presents three additional columns, as shown:

**Figure 17: Custom Data Type columns for defining database retrieval**

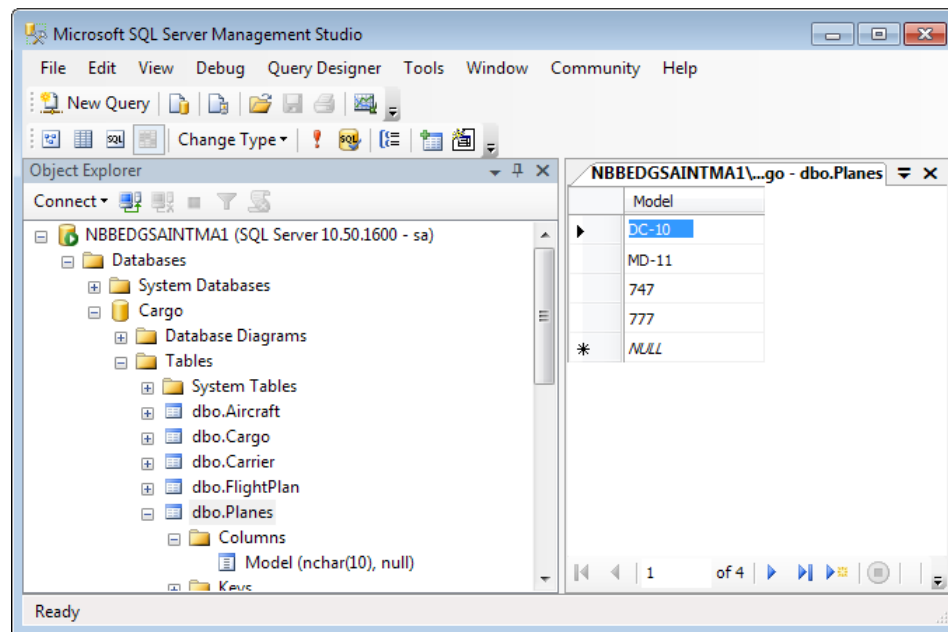

Custom Data Types						
Database Access						
Data Type Name	Base Data Type	Enumeration	Constraint Expression	Lookup Table Name	Labels Column	Values Column
containerType	String	Yes				

These columns are how you specify:

- **Lookup Table Name** - The database syntax that specifies the table that has the enumerations.
- **Labels Column** - The column in the lookup table that holds the label. This is optional as you can elect to use only values.
- **Values Column** - The column in the lookup table that holds the value associated with the label, or the solitary value. This is required.

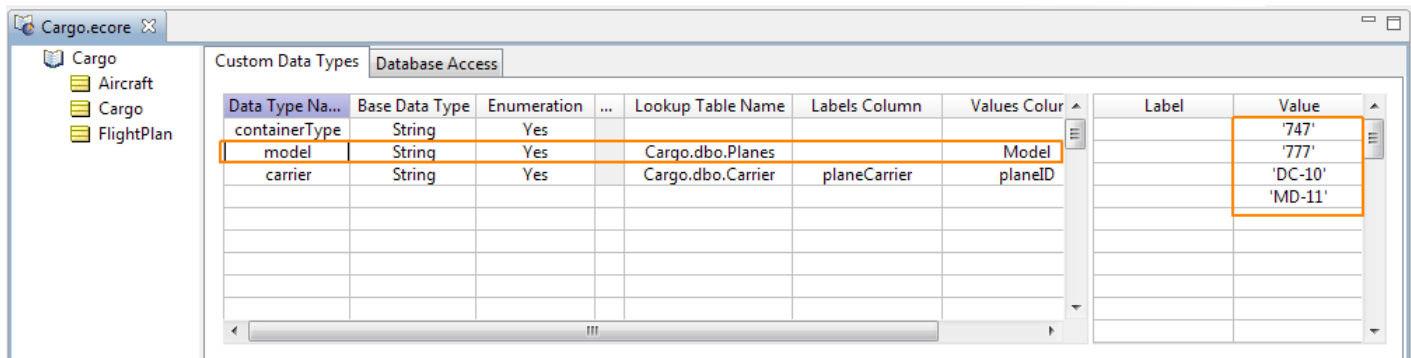

The following examples show two options:

**Figure 18: SQL Server table with values to use in the Vocabulary**

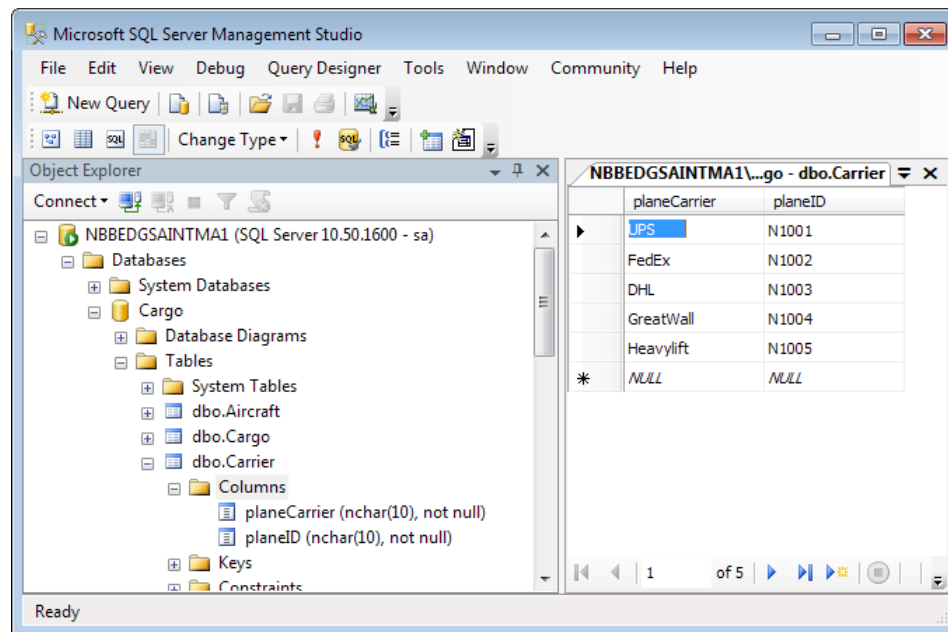

The value data is retrieved into the Vocabulary as highlighted:

**Figure 19: Definition and retrieved values in the Corticon Studio**

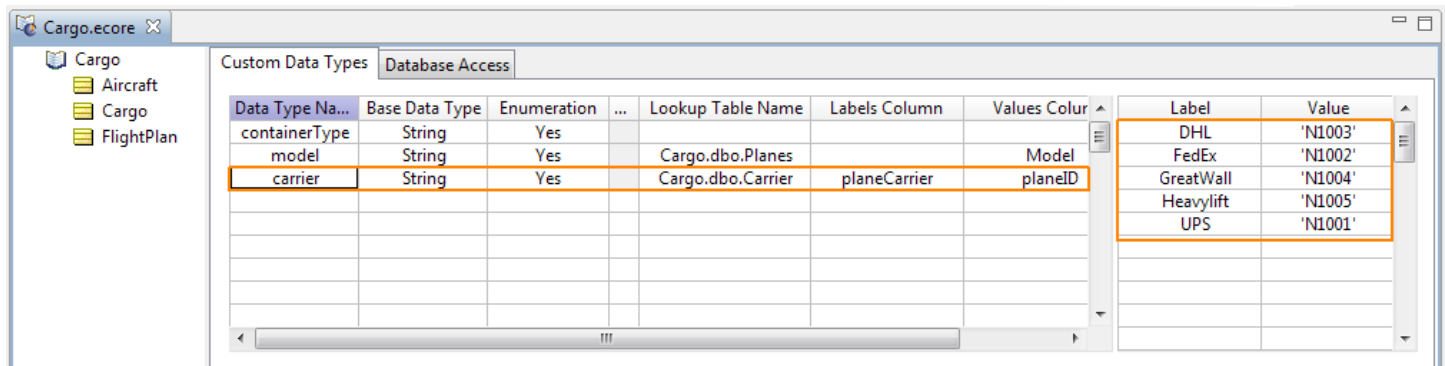

Another example retrieves name-value pairs.

**Figure 20: SQL Server table with labels and values to use in the Vocabulary**

The label-value data is retrieved into the Vocabulary as highlighted:

**Figure 21: Definition and retrieved label-values in the Corticon Studio**

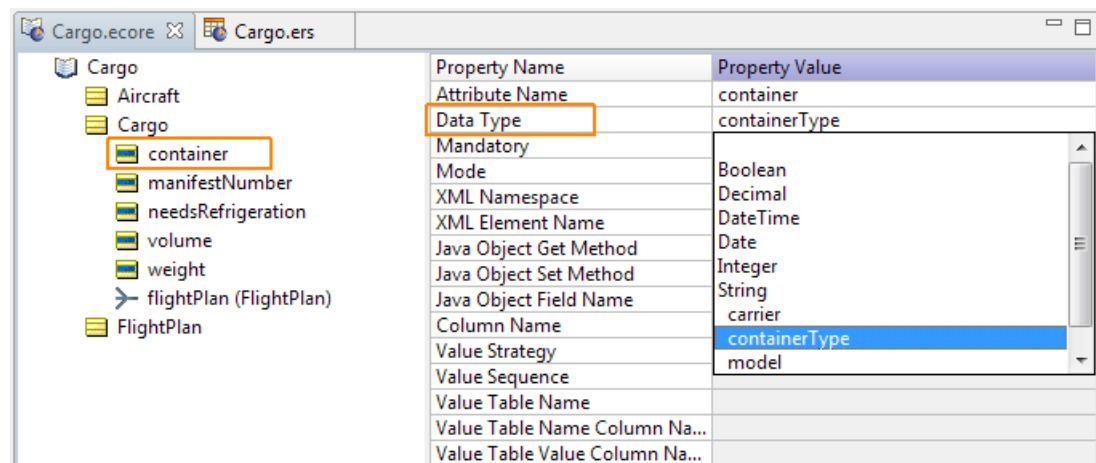

**Note:** This functionality uses Corticon's Enterprise Data Connector. A section of the EDC tutorial covers this topic in detail, *"Importing an attribute's possible values from database tables" in the Using EDC Guide*

## Using Custom Data Types in a Vocabulary

Once a Custom Data Type has been defined as shown above, it may be used and reused throughout the Vocabulary's attribute definitions.

**Figure 22: Using Custom Data Types in the Vocabulary**

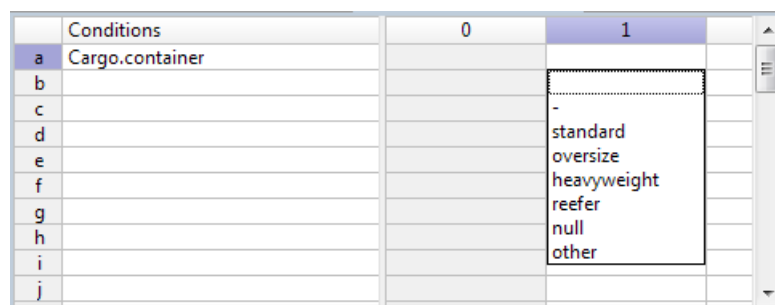

Notice in this figure that multiple attributes can use the same custom data type; the custom data type `containerType` is shown in the drop-down as a sub-category of the String-based data type. The other custom data types will be grouped with their base data types as well.

## Using enumerated Custom Data Types in Rulesheets

Once an enumerated, custom data type has been defined and assigned to an attribute, its labels are displayed in selection drop-downs in both Conditions and Actions expressions, as shown below. If **Labels** are not available (since Labels are optional in an enumerated custom data type's definition), then **Values** are shown. The `null` option in the drop-down is only available if the attribute's **Mandatory** property value is set to `No`.

**Figure 23: Using Custom Data Types in the Rulesheet**

You can test a condition bound to an attribute by evaluating the attribute against a custom data type value using the `#` tag, as shown:

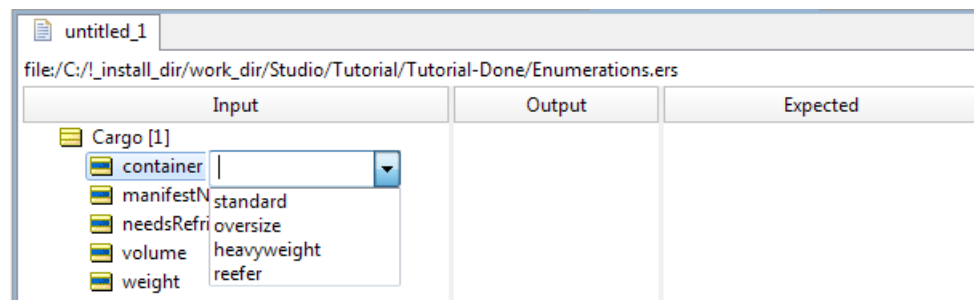

**Figure 24: Using `#` tag to test a custom data type**

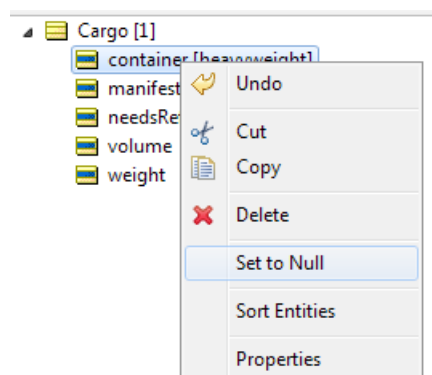

## Using enumerated Custom Data Types in Ruletests

Once an enumerated Custom Data Type has been defined and assigned to an attribute, its enumerated Labels or Values become available as selectable inputs in a Ruletest, as shown:

**Figure 25: Ruletest selecting container's containerType list**

If you want the attribute value to be null, right-click on the attribute and then select **Set to Null**, as shown:

## Relaxing enforcement of Custom Data Types

Using Custom Data Types lets you define general limitations of an attribute's values that are enforced on all Rulesheets and Ruletests in the project and its decision services. While they are valuable in focusing on what is valid in rule designs, violations of the constraints cause rule processing -- Ruletests in Studio; Decision Services in Servers -- to halt at the first constraint violation. Such exceptions indicate that values in attributes are not within numeric constraint ranges or not included in enumerated lists that have been set in the Vocabulary's Custom Data Types.

**Note:** It is recommended that you use relaxed enforcement of CDTs only in test environments. In production, you should enforce data constraints to ensure valid processing by rules.

For Ruleflows, a rule that throw an exception in earlier Rulesheets disables processing subsequent Rulesheets. In the following example, the Advanced Tutorial testsheet outputs the following statements:

Severity	Message	Entity
Info	[Checks,2] The customer is a Preferred Cardholder	Customer[1]
Info	[coupons,2] \$2 off next purchase when 3 or more Soda/Juice items are purchased in a single visit.	ShoppingCart[1]
Info	[coupons,3] 10% off next gas purchase when total is over \$75.	ShoppingCart[1]
Info	[coupons,80] \$1.649800 cashBack bonus earned today, new cashBack balance is \$10.889800.	ShoppingCart[1]
Info	[use__cashBack,1] cashback.bonus has been deducted from the total. New total = \$71.600200. Today's savings = \$10.889800.	ShoppingCart[1]

**Note:** The rule tracing feature reveals which Rulesheets fired which rules.

By defining a Custom Data Type that specifies the `Item` attribute `price` must be greater than zero, and then entering the input value `-1.00` for an item on the testsheet, the first constraint error stops all the subsequent rules from firing:

Severity	Message	Entity
Violation	An unexpected error occurred in Input Data: com.corticon.cdo.ConstraintViolationException: constraint violation setting Item.price to value [-1]	

Relaxing the enforcement of Custom Data Type constraints produces warnings instead of violations, so that development teams and pre-production testing teams can expedite their debugging of rules and error handling, as shown:

Severity	Message	Entity
Warning	constraint violation setting Item.price to value [-1]	Item[3]
Info	The customer is a Preferred Cardholder	Customer[1]
Info	\$2 off next purchase when 3 or more Soda/Juice items are purchased in a single visit.	ShoppingCart[1]
Info	\$1.379800 cashBack bonus earned today, new cashBack balance is \$10.619800.	ShoppingCart[1]
Info	cashback.bonus has been deducted from the total. New total = \$58.370200. Today's savings = \$10.619800.	ShoppingCart[1]

This example might indicate that the applications that format requests should handle the data constraint before forwarding a request into the rules engine.

### Detailed Example

The following example uses the `Cargo` Vocabulary. It has two Custom Data Types, one numeric constraint (assigned to `Cargo.weight` and `Cargo.volume`) and an enumeration list (assigned to `Cargo.container`.)

Custom Data Types					
Data Type Name	Base Data Type	Enumeration	Constraint Expression	Label	Value
containerType	String	Yes		standard	'standard'
positiveInteger	Integer	No	value >=1	oversize	'oversize'
				heavyweight	'heavyweight'
				reefer	'reefer'

A value that is outside the constraints (`Cargo [1] volume = -1`) is noted as violating the attribute's data type constraint on each input attribute and its entity, as well as noted on the **Problems** tab. But when the Ruletest runs, it halts on the first **Violation**, as shown:

untitled\_1  
file:/C:/\_install\_dir/work\_dir/Studio/workspace/Tutorial/Cargo.ers

Input	Output	Expected
Cargo [1]	Cargo [1]	
container [secure]	container [secure]	
volume [-1]	volume [-1]	
weight [100]	weight [100]	

Rule Messages

Severity	Message	Entity
Violation	An unexpected error occurred in Input Data: com.corticon.cdo.ConstraintViolationException: constraint violation setting Cargo.container to value [secure]	

Properties Problems Error Log

0 errors, 2 warnings, 0 others

Description	Resource	Location	Path	Type
Warnings (2 items)				
Value -1 does not pass constraint validation: value >= 1.	Cargo.ert	Cargo [1].volume	/Tutorial	Validation Me...
Value secure is not in defined Values List of the CustomDataType of standard, oversize, heavyweight, reefer	Cargo.ert	Cargo [1].container	/Tutorial	Validation Me...

The details of that first exception are entered in the log (when `loglevel` is `VIOLATION` or higher). No further processing occurs.

By setting the `CcServer` property that relaxes enforcement of Custom Data Types, `com.corticon.vocabulary.cdt.relaxEnforcement=true`, and then restarting the Studio, the errors are still flagged in the data and the **Problem** information is unchanged. However, the **Rule Messages** section flags each of the constraint breaches as a **Warning**, lets them proceed, and then fires all the other rules.

untitled\_1  
file:/C:/\_install\_dir/work\_dir/Studio/workspace/Tutorial/Cargo.ers

Input	Output	Expected
Cargo [1]	Cargo [1]	
container [secure]	container [standard]	
volume [-1]	volume [-1]	
weight [100]	weight [100]	

Rule Messages

Severity	Message	Entity
Warning	constraint violation setting Cargo.container to value [secure]	Cargo[1]
Warning	constraint violation setting Cargo.volume to value [-1]	Cargo[1]
Info	Cargo weighing <= 20,000 kilos must be packaged in a standard container.	Cargo[1]

Properties Problems Error Log

0 errors, 2 warnings, 0 others

Description	Resource	Location	Path	Type
Warnings (2 items)				
Value -1 does not pass constraint validation: value >= 1.	Cargo.ert	Cargo [1].volume	/Tutorial	Validation
Value secure is not in defined Values List of the CustomDataType of standard, oversize, heavyweight, reefer	Cargo.ert	Cargo [1].container	/Tutorial	Validation

**Note:** It is recommended that you create or update the standard last-loaded properties file `brms.properties` to list override properties such as this for Corticon Studios and Servers. See the introductory topics in *"Configuring Corticon properties and settings" in the Server Integration and Deployment Guide* for information on where to locate this properties file.

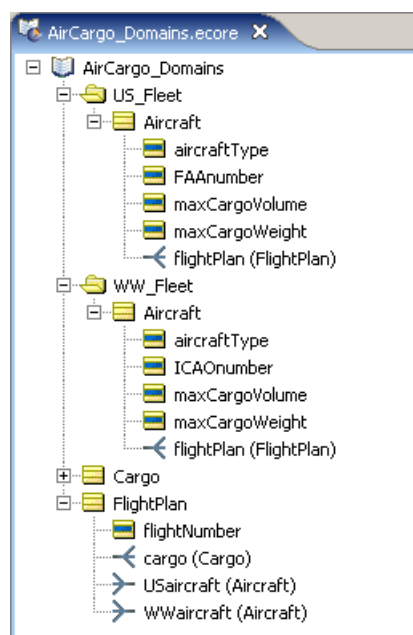

## Domains

Occasionally, it may be necessary to include more than one entity of the same name in a Vocabulary. This can be accomplished using *Domains* (similar to Java *packages* and XML *namespaces*.) Domains allow us to "bundle" one or more entities in a *subset* within the Vocabulary, allowing us to reuse entity names so long as the entity names are unique within each Domain. Additional Domains, referred to as *sub-Domains*, can be defined within other Domains.

Select **Vocabulary > Add Domain** from the *Studio* menubar or click  from the *Studio* toolbar, as shown in *Creating Domains in the Vocabulary*.

A new folder  is listed in the Vocabulary tree. Assign it a name. The example in the following figure shows a Vocabulary with 2 Domains, `US_Fleet` and `WW_Fleet`:

**Figure 26: Using domains in the Vocabulary>**

Notice that the entity `Aircraft` appears in each Domain, using the same spelling and containing slightly different attributes ( `FAANumber` vs. `ICANumber` ). Notice too that the association role names from `FlightPlan` to `Aircraft` have been named manually to ensure uniqueness: one is now `USaircraft` and the other is `WWaircraft`.

## Domains in a Rulesheet

When using entities from domains in a Rulesheet, it is important to ensure uniqueness, which means aliases must be used to distinguish one entity from another.

**Figure 27: Non-unique Entity names prior to defining Aliases**

In *Non-unique Entity names prior to defining Aliases*, both `Aircraft` entities have been dropped into the **Scope** section of the Rulesheet. But because their names are not unique, an error icon  appears. Also, the "fully qualified" domain name has been added after each to distinguish them. By fully qualified, we mean the `::US_Fleet::` designator that follows the first `Aircraft` and `::WW_Fleet::` that follows the second.

But it would be inconvenient (and ugly) to use these fully qualified names in Rulesheet expressions. So we require that you define a unique alias for each. The aliases will be used in the Rulesheet expressions, as shown in *Non-unique Entity names after defining Aliases*.

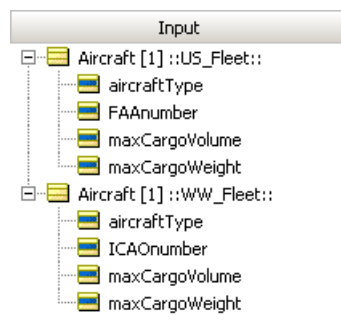

**Figure 28: Non-unique Entity names after defining Aliases**

## Domains in a Ruletest

When using Vocabulary terms in a Ruletest, just drag and drop them as usual. You will notice that they are automatically labeled with the fully qualified name, as shown in **Domains in a Ruletest**.

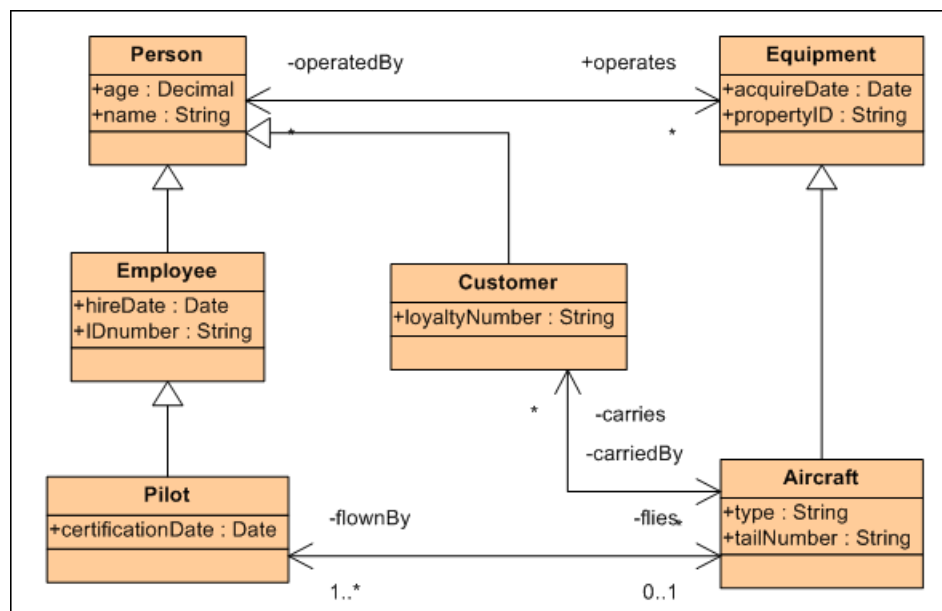

**Figure 29: Domains in a Ruletest**

## Support for inheritance

UML Class diagrams frequently include a modeling/programming concept called inheritance, whereby a class may "inherit" attributes and/or associations from another class. For example:

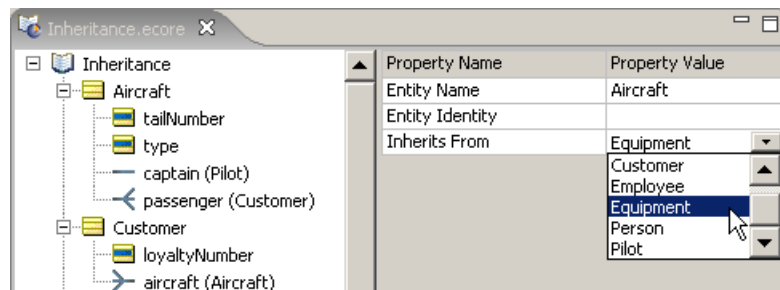

**Figure 30: Rose UML Model Showing Inheritance**

In this diagram, we see a UML model that includes inheritance. The solid-headed arrow symbol indicates that the `Employee` class is a descendant of the `Person` class, and therefore inherits some of its properties. Specifically, the `Employee` class inherits the `age` and `name` attributes from `Person`. In other words, `Employee` has all the same attributes of a `Person` plus two of its own, `hireDate` and `IDnumber`. Likewise, `Aircraft` inherits all of `Equipment`'s attributes (`acquireDate` and `propertyID`) plus has attributes of its own, `type` and `tailNumber`.

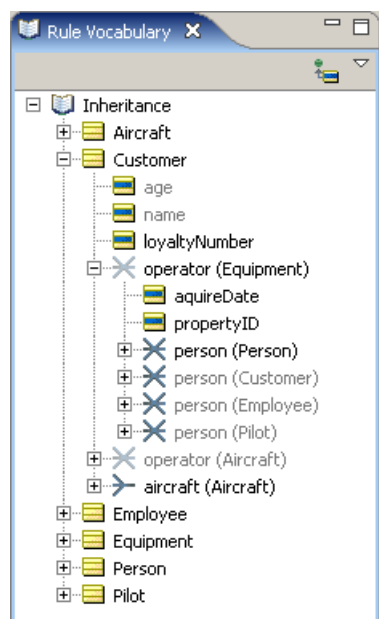

Modeling this UML Class Diagram as a Corticon Vocabulary is straightforward. All Entities, Attributes and Associations are created as per normal practice. To incorporate the elements of inheritance, we only need add one additional setting for each of the descendant entities, as shown:

**Figure 31: Selecting Ancestor Entity for Descendant**

Once all descendant entities have been configured to inherit from their proper ancestor entities, we can save the Vocabulary and view it in the **Rule Vocabulary** window:

**Figure 32: Vocabulary with Inheritance**

Notice that many of the term names and icons are varying shades of gray - these color codes help us to understand the inherited relationships that exist in the Vocabulary.

## Inherited Attributes

Attributes with names displayed in **solid black type**, such as `Customer.loyaltyNumber` in *Vocabulary with Inheritance*, are "native" attributes of that entity.

Attributes with names displayed in **dark gray type**, such as `Customer.age`, are inherited attributes from the ancestor entity (in the case of `Customer`, `Person`).

## Inherited Associations

Inherited Associations are a bit more complicated. An entity may be directly associated with another entity or that entity's descendants. An entity may also inherit an association from its ancestor.

Using the example shown in *Selecting Ancestor Entity for Descendant and Vocabulary with Inheritance* above, let's dissect each of these combinations.

- `Customer.aircraft` is a direct association between `Customer` and `Aircraft` entities. No inheritance is involved, so the association icon is **black** and the rolename is **black**
- `Customer.operator` (Equipment) is an association "inherited" from `Customer`'s ancestor entity `Person`, which has a direct association with `Equipment` and the rolename `operator` in our Vocabulary (the UML Class Diagram in *Selecting Ancestor Entity for Descendant* shows the rolename as `operates` because it is more conventional in UML to use verbs as rolenames, whereas nouns usually make better rolenames in a Corticon Vocabulary). Because the association is inherited from the ancestor's direct association, the icon is **dark gray** and the rolename is **black**.
- `Equipment` (which we can see equally well in the expanded `operator` rolename) has several associations with `Person`. One of these is a direct association with the `Person` entity. In this case, both association icon and rolename are **black**. But `Equipment` also has associations with descendants of the `Person` entity, specifically `Employee`, `Customer`, and `Pilot`. We call these "filtered" associations, and display their rolenames as **dark gray**.
- Finally, `Customer` has another association with `operator` (`Aircraft`) because `Aircraft` is a descendant of `Equipment`. So we combine the "inherited" **dark gray** icon and the "filtered" **dark gray** rolename to display this association.

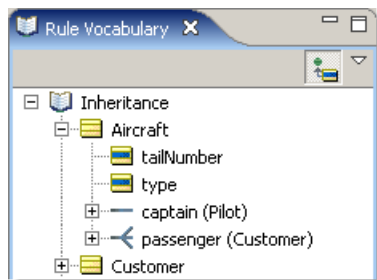

## Controlling the tree view

In cases where a Vocabulary contains inheritance (and includes the various icons and color schemes described above) but the modelers who use it do not intend to use inheritance in their rules, the inherited associations and filtered rolenames can be hidden from view by clicking the

icon in the upper right corner of the Rule Vocabulary window, as shown in *Vocabulary with Inheritance Properties Hidden*:

**Figure 33: Vocabulary with Inheritance Properties Hidden**

`Person` and `Equipment` are associated (using named roles), but what relationship does `Employee` have with `Equipment` or `Aircraft`, if any? This version of Corticon Studio supports inherited associations.

---

**Note:** In versions 4.1 and earlier, Corticon Studio supported inherited attributes only.

---

## Using aliases with inheritance

Any Entity, Attribute, or Association can be dragged into the Scope section for use in Rulesheets. But if two or more terms share the same name, they must be assigned unique alias names before they can be used in rules.

For example, in *Vocabulary with Inheritance*, we see that there are four `Customer.operator.person` terms in the Vocabulary due to the various forms of inheritance used by the entities and associations. If two or more of these nodes are dragged into the Scope window (as shown in *Non-Unique Nodes used in the Scope Window*), they will be assigned error icons  to indicate that their names are not unique. Without unique names, Corticon Studio does not know which one is intended in any rule that uses one of the nodes. To ensure uniqueness, aliases must be assigned and used in rules, as shown in *Uniqueness Established using an Alias*.

**Figure 34: Non-Unique Nodes used in the Scope Window**

**Figure 35: Uniqueness Established using an Alias**

## Inheritance's effects on rule execution

The point of inheritance is not to complicate the Vocabulary. The point is to be able to write rules on ancestor entities and have those rules affect descendant entities automatically. Here are simple examples:

### Inherited Conditions and Actions

A very simple Rulesheet, shown in *Rules written on Employee*, contains 2 rules that test the `age` value of the `Employee` entity. There are no explicit Actions taken by these rules, only the posting of messages.

**Figure 36: Rules written on Employee**

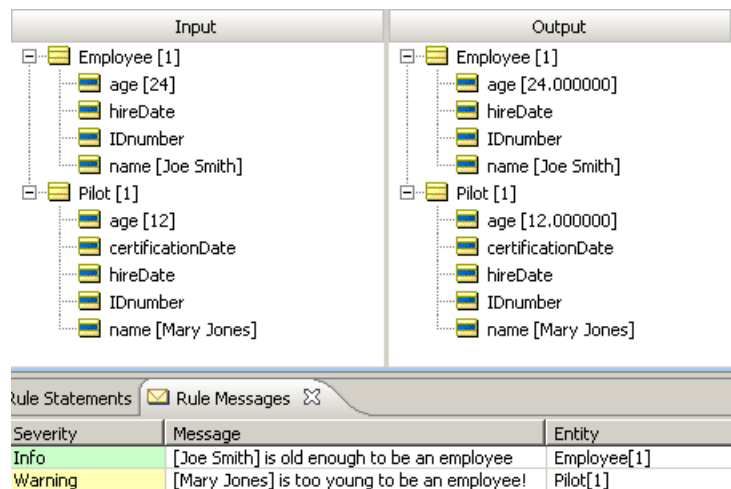

Conditions		0	1	2
a	Employee.age < 18	-	T	F
b				
c				
Actions				
Post Message(s)				
A				
R				
Overrides				

Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1		Warning	Employee	[{Employee.name}] is too young to be an employee!
2		Info	Employee	[{Employee.name}] is old enough to be an employee

A *Ruletest* provides an instance of *Employee* and an instance of *Pilot*. Recall from the Vocabulary that *Pilot* is a descendant of *Employee*, which means it inherits its attributes and associations. But more importantly from a rule execution perspective, a *Pilot* will also be affected by any rules that affect an *Employee*. This is shown in the following figure:

**Figure 37: Inheritance in action**

Using inheritance can be an efficient and powerful way to write rules on many different types of employees (such as pilots, gate agents, baggage handlers, and mechanics) without needing to write individual rules for each.

## Inherited Association

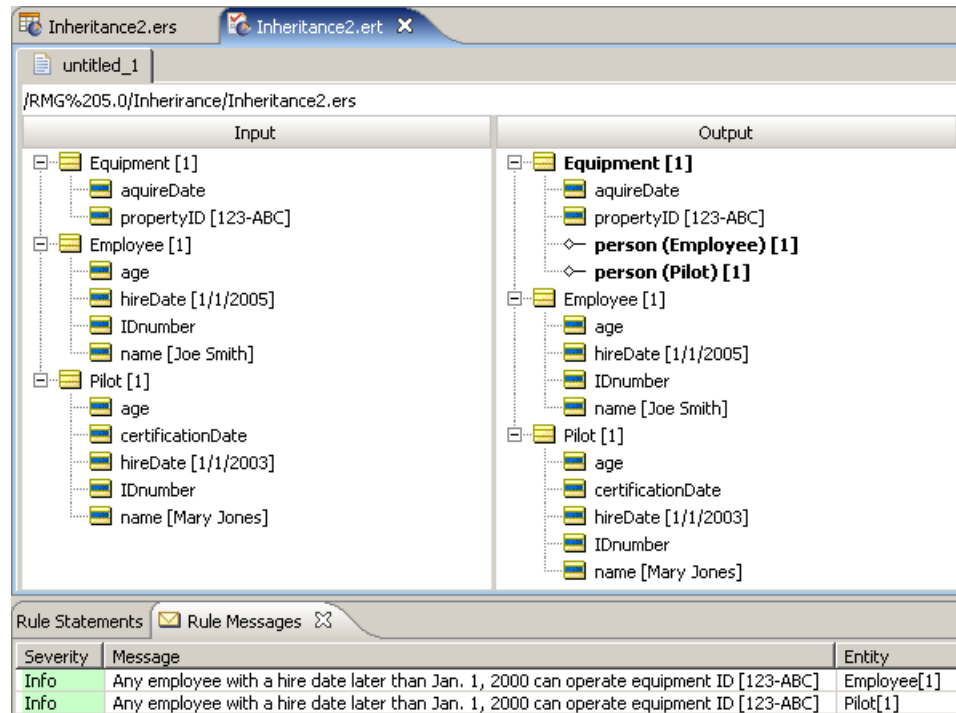

A similar test demonstrates how associations are inherited during rule execution. In this case, we test *Employee.hireDate* to see who's "qualified" to operate a piece of *Equipment*. The `+=` syntax used by the Action row is explained in more detail in the *Rule Language Guide*.

**Figure 38: Rulesheet populating the operators collection**

Ref	ID	Post	Alias	Text
1		Info	Employee	Any employee with a hire date later than Jan. 1, 2000 can operate equipment ID [{Equipment.propertyID}]

Now in, we provide a sample `Equipment` entity, one `Employee`, and one `Pilot`. Both `hireDates` satisfy the rule's Condition (the `Pilot` inheriting `hireDate` from its `Employee` ancestor as before). When the `Employee` is added to the `operators` collection alias, an instance of the association between `Equipment` and `Employee` is created. But what may be surprising is that the same occurs for `Pilot`, which also has an association to `Equipment` that it inherited from `Employee`!

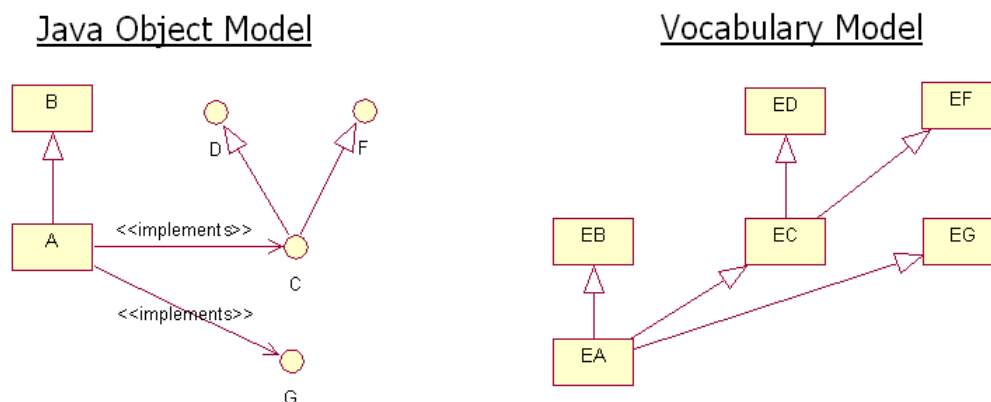

**Figure 39: Inheriting an Association**

## Inheritance and Java object messaging

Each Entity in a Vocabulary can be mapped to a Java Class or Java Interface. Java Classes may have one ancestor. Java Interfaces may have multiple ancestors. A Java Class may implement one or more Interfaces. Say a Java Class A inherits from Java Class B and implements Java Interfaces C & G. Say Java Interface C has as its ancestors Java Interfaces D & F. Say these Classes and Interfaces are mapped to Entities EA, EB, EC, ED, EF & EG in the Vocabulary. The relationships amongst the Java Classes shall be reflected in the Vocabulary using multiple inheritance. Entity EA shall have as its ancestors Entities EB, EC & EG. Entity EC shall have as its ancestors entities ED & EF as shown below:

**Figure 40: How the Vocabulary Incorporates Inheritance from a Java Object Model**

When a collection of Java objects are passed into the engine through the JOM API, the Java translator determines how to map them to the internal Entities using the following algorithm:

Naming conventions used in the graphic above:

- DS = Decision Service
- JO = Java Object in input collection
- JC = Java Class for the JO and any of its direct or indirect ancestors
- JI = Java Interfaces implemented directly or indirectly by JO
- E = A Vocabulary Entity with no descendants found in DS context
- AE = An Ancestor Entity (one with descendants) found in DS context
- CDO = In memory Java Data Object created by Corticon for use in rule execution

For each E:

- If there is a JO whose JC or JI is mapped to E then
  - Instantiate a CDO for E and link to JO
  - Put CDO in E bucket
- Traverse E's inheritance hierarchy one level up
  - For each AE discovered in current level:
    - Put CDO in AE bucket
- If E has another level of inheritance hierarchy, repeat last step

This design effectively attempts to instantiate the minimum number of CDOs possible and morphs them into playing multiple Entity roles. Ideally, no duplicate copies of input data exists in the engine's working memory thus avoid data synchronization issues.

## Test yourself - questions – building the vocabulary

---

**Note:** Try this test, and then go to **Answers:** [Building the vocabulary](#) on page 279 to correct yourself.

---

1. Give 3 functions of the Vocabulary.
2. True or False: All Vocabulary terms must also exist in the object or data model?
3. True or False: All terms in the object or data model must also exist in the Vocabulary?
4. True or False: In order to create the Vocabulary, an object or data model must already exist.
5. The Vocabulary is an \_\_\_\_\_ model, meaning many of the real complexities of an underlying data model are hidden so that the rule author can focus on only those terms relevant to the rules.
6. The UML model that contains the same types of information as a Vocabulary is called a \_\_\_\_\_
7. What are the three components (or nodes) of the Vocabulary?
8. Which of the following are acceptable attribute names?

Hair_color	hairColor	HairColor	hair color
------------	-----------	-----------	------------

9. Which color is used in the Entity icon?
10. Which of the three Vocabulary components can hold an actual value?
11. What are the five main data types used by Vocabulary attributes?
12. Which colors are used in the Base attribute icon?
13. Which colors are used in the Extended Transient attribute icon?
14. What is the purpose of an Extended Transient Vocabulary term?
15. Associations are \_\_\_\_\_ by default.

16. Association icons indicate:

optionality	singularity	cardinality	musicality
-------------	-------------	-------------	------------

17. Which of the following icons represents a one-to-many association?

			
---	---	---	---

18. Which of the following icons represents a one-to-one association?

			
---	---	---	---

19. If an association is one-directional *from* the Source entity *to* the Target entity, then which term is not available in the Vocabulary?

Target.attribute	Target.source.attribute	Source.target.attribute	Source.attribute
------------------	-------------------------	-------------------------	------------------

20. The default role name of an association *from* the Source entity to the Target entity is:

role1	source	target	theTarget
-------	--------	--------	-----------

21. Sketch a model for the following scenario:

A Purchase Order has a customer name, order date, total amount and an unlimited number of Line Items. Each Line Item has a part number, quantity, price-per-unit and total price.

22. Create a Corticon Studio Vocabulary for the model sketched in 22.

23. List the (4) steps in generating a Vocabulary from scratch.

24. Cardinality of an association determines:

- a. The number of possible associated entities.
- b. The number of attributes for each entity.
- c. The number of associations possible within an entity.
- d. The number of attributes for each association.

25. The Vocabulary terms are the nouns of Corticon rules. What are the verbs?

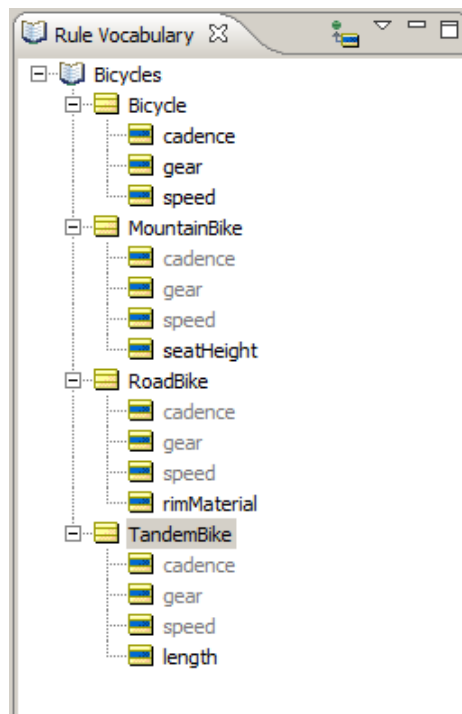

26. What Corticon document contains the complete list of all Vocabulary Operators, descriptions of their usage, and actual examples of use in Rulesheets?

27. True or False. In addition to the supported vocabulary data types, you can create *any* type of custom data type you want?

28. You must name your custom data type. Which of the following are *not* custom data type naming convention requirements?

- a. Cannot match any other vocabulary entity names
- b. May match other Custom Data Type Names

- c. Base Data Type names may not be re-used.
  - d. The name must comply with the standard entity naming rules.
29. True or False. The Enumeration section of the Custom Data Types exposes the Label/Value columns and allows you to create a list of acceptable value rows.
30. Selecting `no` in the *Enumeration* section of the Custom Data Types enables the Constraint Expression. Give an example of a Constraint Expression:
- \_\_\_\_\_
31. True or False. Constraint Expressions must be equivalent to a Boolean expression to be valid.
32. In an Enumeration, are both the **Label** and **Value** columns required?
33. When you create Enumerated Custom data Types, which of the following are acceptable entries for the Value column:
- |            |              |        |          |
|------------|--------------|--------|----------|
| 12/12/2011 | "12/12/2011" | Airbus | 'Airbus' |
|------------|--------------|--------|----------|
34. Name an advantage to using Enumerated Custom Data Types when it comes to testing your rules in a Ruletest.
35. Explain what Domains do in the Vocabulary?
36. True or False. If you use a Domain, then you will be required to create an alias for each unique Entity/Domain pair?
37. True or False. Inheritance can be modeled in a Vocabulary.
38. In the following vocabulary, which Entities have "native" attributes and which Entities has "inherited" attributes?

39. Give two examples of inherited attributes from the vocabulary above:

- \_\_\_\_\_
40. True or False. Using Inheritance can be a way to write efficient and powerful rules. For example, one rule could be used to modify the cadence attribute for all the entities in the Vocabulary example above.

---

## Rule scope & context

---

The air cargo example that we started in the Vocabulary chapter is continued here to illustrate the important concepts of *scope* and *context* in rule design.

A quick recap of the fact model:

**Figure 41: Fact Model**

According to this Vocabulary, an Aircraft is related to a Cargo shipment through a FlightPlan. In other words, it is the FlightPlan that connects or relates an Aircraft to its Cargo shipment. The Aircraft, by itself, has *no direct relationship* to a Cargo shipment unless it is scheduled by a FlightPlan; or, no Aircraft may carry a Cargo shipment without a FlightPlan. Similarly, no Cargo shipment may be transported by an Aircraft without a FlightPlan. These facts constitute business rules in and of themselves and constrain creation of other rules because they define the Vocabulary we will use to build all subsequent rules in this scenario.

Also recall that the company wants to build a system that automatically checks flight plans to ensure no scheduling rules or guidelines are violated. One of the many business rules that need to be checked by this system is:

1. An Aircraft must not carry a Cargo shipment that exceeds its maximum Cargo weight

With our Vocabulary created, we can build this rule in the Studio. As with many tasks in Studio, there is often more than one way to do something. We will explore two possible ways to build this rule – one correct and one incorrect.

To begin with, we will write our rule using the "root-level" terms in the Vocabulary. In the following figure, column #1 (the **true** Condition) is the rule we are most interested in – we've added the **false** Condition in column #2 simply to show a logically complete Rulesheet.

**Figure 42: Expressing the Rule Using "Root-Level" Vocabulary Terms**

The screenshot displays the Rule Studio interface. On the left, the 'Rule Vocabulary' pane shows a tree structure for 'airCargo' containing 'Aircraft' (with attributes: aircraftType, maxCargoVolume, maxCargoWeight, tailNumber) and 'Cargo' (with attributes: manifestNumber, packaging, volume, weight). The main workspace shows a rule configuration for 'airCargo.ecore' with a 'rootLevelScope.ers' file. The 'Conditions' section has a table with columns 0, 1, and 2. Row 'a' contains the condition 'Cargo.weight > Aircraft.maxCargoWeight' in column 0, 'T' in column 1, and 'F' in column 2. The 'Actions' section has a 'Post Message(s)' table with rows A, B, and C. Row A has a message icon in column 1. The 'Rule Messages' pane at the bottom shows two messages: a violation message (Ref 1) and an info message (Ref 2).

Ref	Post	Alias	Text
1	Violation	Cargo	Cargo [{Cargo.weight}] is too heavy for Aircraft [{Aircraft.tailNumber}]
2	Info	Cargo	Cargo [{Cargo.weight}] may be carried by Aircraft [{Aircraft.aircraftT

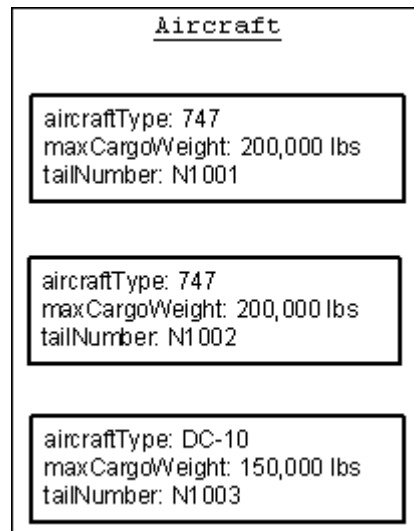

Refer to the *Embedding Attributes in Posted Rule Statements* section of the *Rule Language Guide* for additional details regarding the syntax introduced in the **Rule Statements** portion of the following figure, example 5, in the [Custom data types](#) topic.

We can build a Ruletest to test the rule using the Cargo company's actual data, as follows:

---

The company owns 3 Aircraft, 2 747s and a DC-10, each with different tail numbers. The 3 Aircraft are shown in the following figure, example 6 in the [Custom data types](#) topic. Each box represents a real-life example (or *instance*) of the `Aircraft` term from our Vocabulary.

**Figure 43: The Cargo Company's 3 Aircraft**

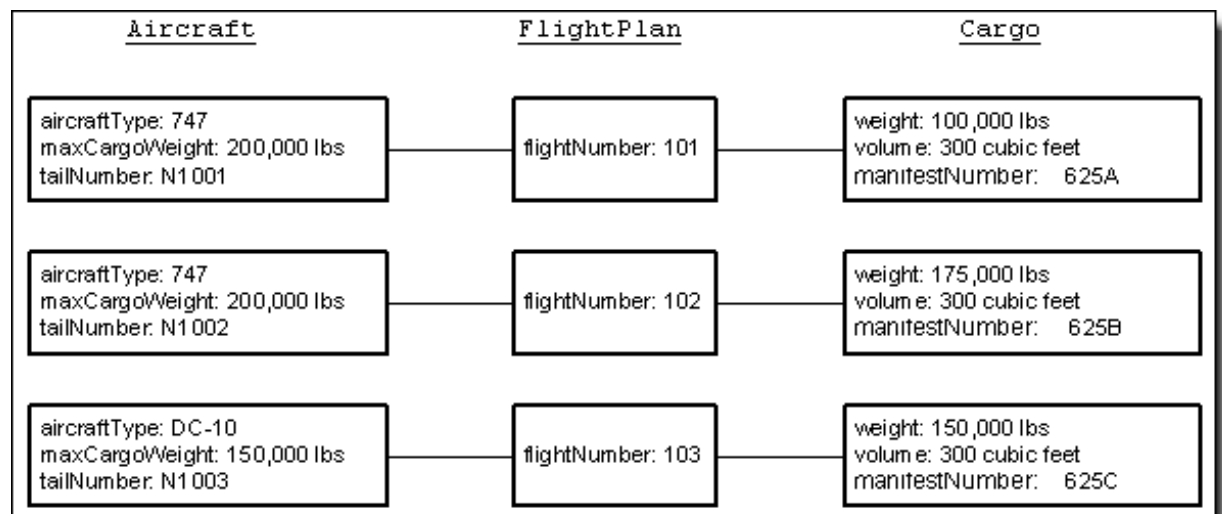

These `Aircraft` give the company the ability to schedule 3 `Cargo` shipments each night {there is another business rule implied here – "an Aircraft must not be scheduled for more than one flight per night", but we won't address this now because it is not relevant to the discussion}. On a given night, the `Cargo` shipments look like those shown below. Again, like the `Aircraft`, these `Cargo` shipments represent specific *instances* of the generic `Cargo` term from the Vocabulary.

**Figure 44: The 3 Cargo Shipments for the Night of June 25th**

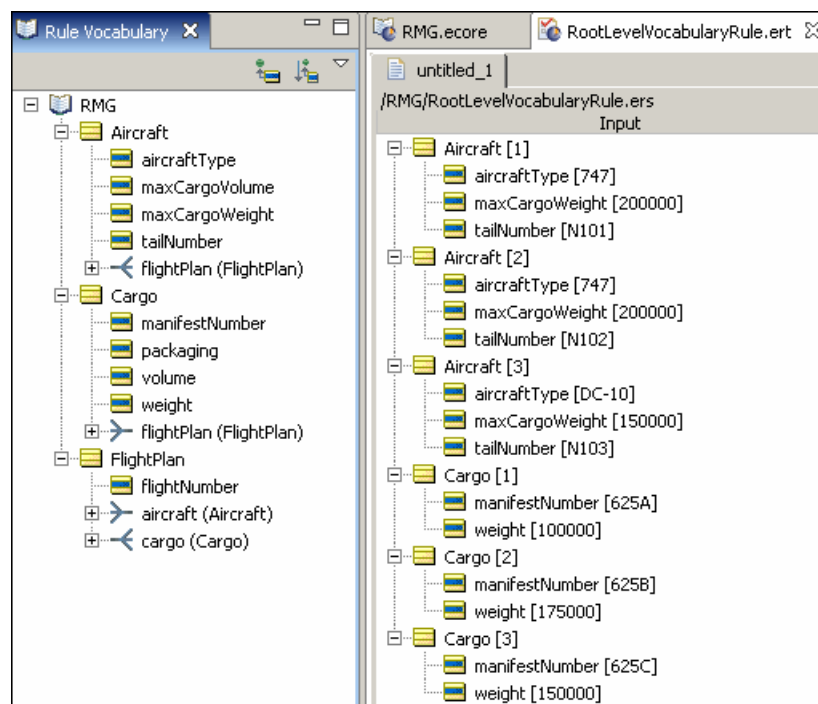

Finally, our sample business process manually matches specific aircraft and cargo shipments together as three flightplans, shown below. This organization of data is consistent with the structure and constraints implicit in our Vocabulary.

**Figure 45: The 3 FlightPlans with their related Aircraft and Cargo instances**

We can construct a Ruletest (in the following figure) so that the company's actual data will be evaluated by the rule. Since the rule used "root-level" Vocabulary terms in its construction, we will use "root-level" terms in the Ruletest as well:

**Figure 46: Test the Rule Using "Root-Level" Vocabulary Terms**

Running the Ruletest :

**Figure 47: Results of the Ruletest**

The screenshot displays the Ruletest interface with three tabs: 'airCargo.ecore', 'rootLevelScope.ers', and 'rootLevelScope.ert'. The main window shows a tree view of the input and output data. The input tree on the left lists three aircraft (Aircraft [1], [2], [3]) and three cargo items (Cargo [1], [2], [3]). The output tree on the right shows the same data but with additional numerical values for 'maxCargoWeight' and 'weight'. Below the trees, the 'Rule Messages' tab is active, showing a table of messages.

Severity	Message	Entity
Violation	Cargo [625B] is too heavy for Aircraft [N103]	Cargo[2]
Info	Cargo [625C] may be carried by Aircraft [N101]	Cargo[3]
Info	Cargo [625B] may be carried by Aircraft [N101]	Cargo[2]
Info	Cargo [625A] may be carried by Aircraft [N101]	Cargo[1]
Info	Cargo [625C] may be carried by Aircraft [N103]	Cargo[3]
Info	Cargo [625A] may be carried by Aircraft [N103]	Cargo[1]
Info	Cargo [625C] may be carried by Aircraft [N102]	Cargo[3]
Info	Cargo [625B] may be carried by Aircraft [N102]	Cargo[2]
Info	Cargo [625A] may be carried by Aircraft [N102]	Cargo[1]

Note the messages returned by the Ruletest. Recall that the intent of the rule is to verify whether a given `Flightplan` is in violation by scheduling a `Cargo` shipment that is too heavy for the assigned `Aircraft`. But we already know there are only three `Flightplans`. And we also know, from examination of **The 3 FlightPlans with their related Aircraft and Cargo instances**, that the combination of aircraft `N1003` and cargo `625C` does not appear in any of our three `Flightplans`. So why was this combination, one that does not actually exist, evaluated? For that matter, why has the rule fired *nine* times when only *three* sets of `Aircraft` and `Cargo` were present? The answer lies in the way we defined our rule, and in the way the Corticon Server evaluated it.

We gave the Ruletest three instances of both `Aircraft` and `Cargo`. Studio treats `Aircraft` as a "collection" or "set" of these three specific instances. When Studio encounters the term `Aircraft` in a rule, it applies all instances of `Aircraft` found in the Ruletest (all three instances in this example) to the rule. Since both `Aircraft` and `Cargo` have three instances, there are a total of nine *possible combinations* of the two terms. In the following figure, the set of these nine possible combinations is called a "cross product", "Cartesian product", or "tuple set" in different disciplines. We tend to use cross-product when describing this outcome.

**Figure 48: All Possible Combinations of Aircraft and Cargo**

One pair, the combination of manifest 625B and plane N1003 (shown as the red arrow in the figure above), is indeed illegal, since the plane, a DC-10, can only carry 150,000 lbs, while the cargo weighs 175,000 lbs. But this pairing does not correspond to any of the three `FlightPlans` created. Many of the other combinations evaluated (five others, to be exact) are not represented by real flight plans either. So why did Studio bother to perform three times the necessary evaluations? It is because our rule, as implemented in [Figure 42](#) on page 56, does not capture the essential elements of **scope** and **context**.

We want our rule to express the fact that we are only interested in evaluating the `Cargo-Aircraft` pair for *each* `FlightPlan`, not for *all* possible combinations. How do we express this intention in our rule? We use the associations included in the Vocabulary.

Refer to the following figure:

**Figure 49: Rule Expressed Using `FlightPlan` as the Rule Scope**

The screenshot shows the Rule Editor interface. On the left is the Rule Vocabulary tree. In the center is the rule editor with conditions and actions. On the right is a table of Rule Messages.

**Rule Vocabulary:**

- airCargo
  - Aircraft
    - flightNumber
    - aircraft (Aircraft)
      - aircraftType
      - maxCargoVolume
      - maxCargoWeight
      - tailNumber
  - Cargo (Cargo)
    - manifestNumber
    - packaging
    - volume
    - weight

**Rule Editor:**

Conditions:

	0	1	2
a	FlightPlan.cargo.weight > FlightPlan.aircraft.maxCargoWeight		
b		T	F
c			

Actions:

Post Message(s):

	0	1	2
A			
B			

Overrides:

**Rule Messages:**

Ref	Post	Alias	Text
1	Violation	FlightPlan	Cargo [{FlightPlan.cargo.manifestNumber}] is too heavy for Aircraft [{FlightPlan.aircraft.tailNumber}].
2	Info	FlightPlan	Cargo [{FlightPlan.cargo.manifestNumber}] may be carried by Aircraft [{FlightPlan.aircraft.tailNumber}].

Here, we've rewritten the rule using the `aircraft` and `cargo` terms from *inside* the `FlightPlan` term.

---

**Note:** By "inside" we mean the `aircraft` and `cargo` terms that appear when the `FlightPlan` term is opened in the Vocabulary tree, as shown by the orange circles in **Rule Expressed Using `FlightPlan` as the Rule Scope**.

---

This is significant. It means we want the rule to evaluate the `Cargo` and `Aircraft` terms *only in the context of* a `FlightPlan`. For example, on a different night, the Cargo company might have eight Cargo shipments assembled, but only the same three planes on which to carry them. In this scenario, three flight plans would still be created. Should the rule evaluate all eight Cargo shipments, or only those three associated with actual flight plans? From the original business rule, it is clear we are only interested in evaluating those Cargo shipments *in the context of* actual flight plans. To put it differently, the rule's application is limited to only those `Cargo` shipments assigned to a specific `Aircraft` via a specific `FlightPlan`. We express these relationships in the Rulesheet by including the `FlightPlan` term in the rule, so that `cargo.weight` is properly expressed as `FlightPlan.cargo.weight`, and `Aircraft.maxCargoWeight` is properly expressed as `FlightPlan.aircraft.maxCargoWeight`. By attaching `FlightPlan` to the terms `aircraft.maxCargoWeight` and `cargo.weight`, we have indicated mandatory *traversals* of the associations between `FlightPlan` and the other two terms, `Aircraft` and `Cargo`. This instructs Corticon Server to evaluate the rule using the intended context. In writing rules, it is extremely important to understand the context of a rule and the scope of the data to which it will be applied.

For details, see the following topics:

- [Rule scope](#)
- [Aliases](#)
- [Scope and perspectives in the vocabulary tree](#)
- [Test yourself: Rule scope and context](#)

## Rule scope

Because the rule is evaluating both `Cargo` and `Aircraft` in the context of a `FlightPlan`, we say that the rule has *scope*, which means that *the rule evaluates only that data which matches the rule's scope*. This has an interesting effect on the way the rule is evaluated. When the rule is executed, its scope ensures that the Corticon Server evaluates only those pairings that *match the same* `FlightPlan`. This means that a `cargo.weight` will **only** be compared to an `aircraft.maxCargoWeight` **if both the cargo and the aircraft share the same** `FlightPlan`. This simplifies rule expression greatly, because it eliminates the need for us to specify *which* `FlightPlan` we are talking about for each `Aircraft`-`Cargo` combination. When a rule has context, the system takes care of this matching automatically by sending *only* those `Aircraft` - `Cargo` pairs that *share the same* `FlightPlan` to be evaluated by the rule. And, since Corticon Studio automatically handles multiple instances as *collections*, it sends *all* pairs to the rule for evaluation.

---

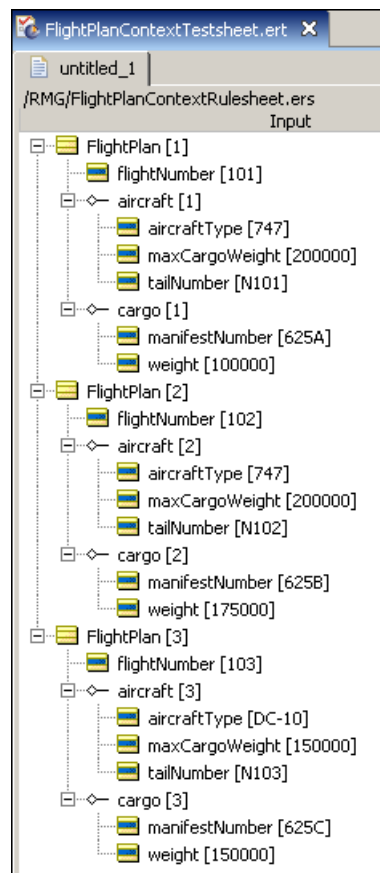

**Note:** See the following topic, [Collections](#), for a more detailed discussion of this subject.

---

To test this new rule, we need to structure our Ruletest differently to correspond to the new structure of our rule and reflect the rule's scope. For more information on the mechanics of creating associations in Ruletests, also refer to the "Set Up the Ruletest Scenario" section in the *Corticon Studio Tutorial: Basic Rule Modeling* and the "Creating Associations" chapter in the *Quick Reference Guide*.

Finally, one `FlightPlan` is created for each `Aircraft-Cargo` pair. This means a total of three `FlightPlans` are generated each night. Using the terms in our Vocabulary and the relationships between them, we have the possibilities shown in [Figure 45](#) on page 58. The rule will evaluate these combinations and identify any violations.

**Figure 50: New Ruletest Using `FlightPlan` as the Rule Scope**

What is the expected result from this Ruletest? If the results follow the same pattern as in the first Ruletest, we might expect the rule to fire nine times (three `Aircraft` evaluated for each of three `Cargo` shipments).

But refer to *Ruletest Results Using Scope – Note no Violations* and you will see that the rule, in fact, fired only 3 times – and only for those *Aircraft*-*Cargo* pairs that are related by common *FlightPlans*. This is the result we want. The Ruletest shows that there are no *FlightPlans* in violation of our rule.

**Figure 51: Ruletest Results Using Scope – Note no Violations**

The screenshot displays the Ruletest Results Using Scope interface. The top section shows the rule's input and output entities. The input side lists three FlightPlans (FlightPlan [1], FlightPlan [2], FlightPlan [3]), each with associated aircraft (Aircraft) and cargo (Cargo) entities. The output side shows the same structure. Below the tree view, there is a table of Rule Messages showing three informational messages about cargo being carried by aircraft.

Severity	Message	Entity
Info	Cargo [625A] may be carried by Aircraft [N101]	FlightPlan[1]
Info	Cargo [625B] may be carried by Aircraft [N102]	FlightPlan[2]
Info	Cargo [625C] may be carried by Aircraft [N103]	FlightPlan[3]

One final point about scope: it is critical that the context you choose for your rule supports the intent of the business decision you are modeling. At the very beginning of our example, we stated that the purpose of the application is to check flightplans *that have already been created*. Therefore, the context of our rule was chosen so that the rule's design was consistent with this goal – no aircraft-cargo combinations should be evaluated unless they are already matched up via a common flightplan.

But what if our business purpose had been different? What if the problem we are trying to solve was modified to: "Of all possible combinations of aircraft and cargo, determine which pairings must **not** be included in the same FlightPlan." The difference here is subtle but important. Before, we were identifying invalid combinations of pre-existing FlightPlans. Now, we are trying to identify invalid combinations from all possible cargo-aircraft pairings. This other rule might be the first step in a screening or filtering process designed to discard all the invalid combinations. In this case, the original rule we built, root-level context, would be the appropriate way to implement our intentions, because now we are looking at all possible combinations *prior to creating new FlightPlans*.

# Aliases

To clean up and simplify rule expression, Corticon Studio allows you to declare *aliases* in a Rulesheet. Using an alias to express scope results in a less cluttered Rulesheet.

To define an alias, you need to open the **Scope** tab on the Rulesheet. Either click the toolbar

button to open the advanced view, or choose the Rulesheet menu toggle **Advanced View**.

If rules have already been modeled in the Rulesheet, then the **Scope** window already contains those Vocabulary terms used in the rules so far. If rules have not yet been modeled, then the Scope window is empty.

To define an alias, double-click to the term, and then type a unique name in the entry box, as shown:

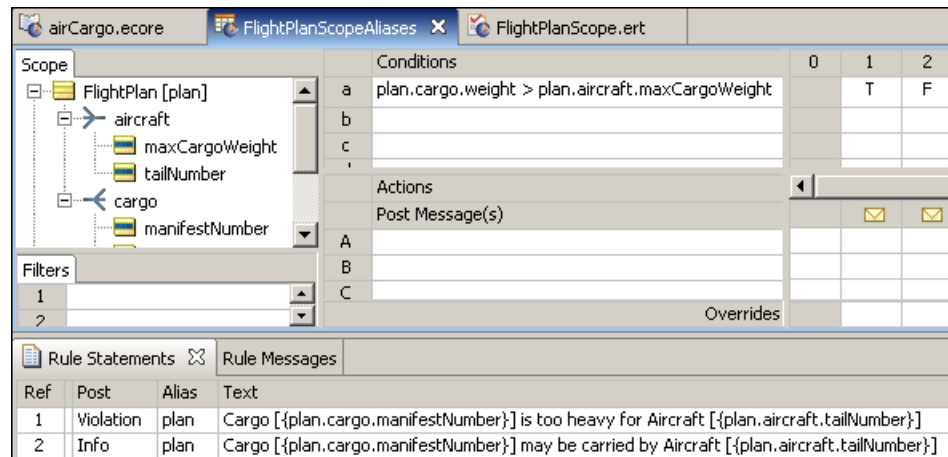

**Figure 52: Defining an Alias in the Scope window**

Once an alias is defined, any subsequent rule modeling in the Rulesheet automatically substitutes the alias for the Vocabulary term it represents.

In *Rulesheet with FlightPlan Alias Declared in the Scope Section*, notice that the terms in the Condition rows of the Rulesheet do not show the `FlightPlan` term. That's because the alias `plan` substitutes for `FlightPlan`. The small "c" in `cargo` and "a" in `aircraft` provide other clues that these terms exist *within the context* of the `FlightPlan` term defined in the **Scope** window.

**Figure 53: Rulesheet with `FlightPlan` Alias Declared in the Scope Section**

Once an alias is defined, any new Vocabulary term dropped onto the Rulesheet is adjusted accordingly. For example, dragging and dropping `FlightPlan.cargo.weight` onto the Rulesheet displays as `plan.cargo.weight`.

Aliases work in all sections of the Rulesheet, including the **Rule Statement** section. Modifying an alias name defined in the Scope section causes the name to update everywhere it is used in the Rulesheet.

**Note:** Rules modeled without aliases do not update automatically if aliases are defined later. So if you intend to use aliases, define them as you start your rule modeling - that way they apply automatically when you drag and drop from the Vocabulary or Scope windows.

## Scope and perspectives in the vocabulary tree

Because our Vocabulary is organized as a "tree" view in Corticon Studio, it may be helpful to extend the tree analogy to better understand what aliases do. The tree view permits us to use the business terms from a number of different "perspectives", each perspective corresponding to one of the root-level terms and an optional set of one or more branches.

Table 1: Table: Vocabulary Tree Views and Corresponding Branch Diagrams

Vocabulary Tree	Description	Branch Diagram
 <p>A screenshot of a vocabulary tree with 'FlightPlan' as the root. It has three main branches: 'flightNumber', 'flightRange', and 'aircraft (Aircraft)'. The 'aircraft' branch further branches into 'aircraftType', 'maxCargoVolume', 'maxCargoWeight', and 'tailNumber'. The 'cargo (Cargo)' branch branches into 'manifestNumber', 'packaging', 'volume', and 'weight'.</p>	<p>This portion of the Vocabulary tree can be visualized as the branch diagram shown to the right. Because this piece of the Vocabulary begins with the FlightPlan "root", the branches also originate with the FlightPlan root or trunk. The FlightPlan's associated cargo and aircraft terms are branches from the trunk.</p> <p>Any rule expression that uses FlightPlan, FlightPlan.cargo, or FlightPlan.aircraft is using scope from this perspective of the Vocabulary tree.</p>	 <p>A branch diagram showing a vertical line representing the 'FlightPlan' root. Two horizontal lines branch off from this vertical line, labeled 'cargo' and 'aircraft'.</p>
 <p>A screenshot of a vocabulary tree with 'Aircraft' as the root. It has three main branches: 'aircraftType', 'maxCargoVolume', 'maxCargoWeight', and 'tailNumber'. The 'flightPlan (FlightPlan)' branch branches into 'flightNumber', 'flightRange', and 'cargo (Cargo)'. The 'cargo' branch branches into 'manifestNumber', 'packaging', 'volume', and 'weight'.</p>	<p>This portion of the Vocabulary tree begins with Aircraft as the root, with its associated flightPlan branching from the root. A cargo, in turn, branches from its associated flightPlan.</p> <p>Any rule expression that uses Aircraft, Aircraft.flightPlan, or Aircraft.flightPlan.cargo is using scope from this perspective of the Vocabulary tree.</p>	 <p>A branch diagram showing a vertical line representing the 'Aircraft' root. A horizontal line branches off from this vertical line, labeled 'flightPlan'. Another horizontal line branches off from the 'flightPlan' line, labeled 'cargo'.</p>
 <p>A screenshot of a vocabulary tree with 'Cargo' as the root. It has three main branches: 'manifestNumber', 'packaging', 'volume', and 'weight'. The 'flightPlan (FlightPlan)' branch branches into 'flightNumber', 'flightRange', and 'aircraft (Aircraft)'. The 'aircraft' branch branches into 'aircraftType', 'maxCargoVolume', 'maxCargoWeight', and 'tailNumber'.</p>	<p>This portion of the Vocabulary tree begins with Cargo as the root, with its associated flightPlan branching from the root. An aircraft, in turn, branches from its associated flightPlan.</p> <p>Any rule expression that uses Cargo, Cargo.flightPlan, or Cargo.flightPlan.aircraft is using scope from this perspective of the Vocabulary tree.</p>	 <p>A branch diagram showing a vertical line representing the 'Cargo' root. A horizontal line branches off from this vertical line, labeled 'flightPlan'. Another horizontal line branches off from the 'flightPlan' line, labeled 'aircraft'.</p>

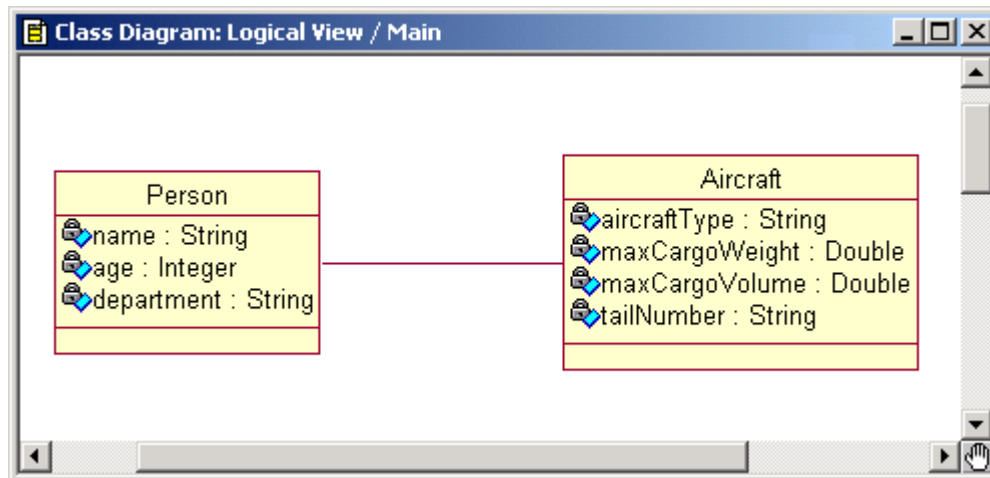

Scope can also be thought of as hierarchical, meaning that a rule written with scope of `Aircraft` applies to all root-level `Aircraft` data. And other rules using some piece (or branch) of the tree beginning with root term `Aircraft`, including `Aircraft.flightPlan` and `Aircraft.flightPlan.cargo`, also apply to this data and its associated collections. Likewise, a rule written with scope of `Cargo.flightPlan` does not apply to root-level `FlightPlan` data.

This provides an alternative explanation for the different behaviors between the *Rulesheets* in [Expressing the Rule Using Root-Level Vocabulary Terms](#) and [Rule Expressed Using FlightPlan as the Rule Scope](#). The rules in [Expressing the Rule Using Root-Level Vocabulary Terms](#) are written using different root terms and therefore different scopes, whereas the rules in [Rule Expressed Using FlightPlan as the Rule Scope](#) use the same `FlightPlan` root and therefore share common scope.

## Roles

Using roles in the Vocabulary can often help to clarify rule context. To illustrate this point, we will use a slightly different example. The UML class diagram for a new (but related) sample Vocabulary is as shown:

**Figure 54: UML Class Diagram without Roles**

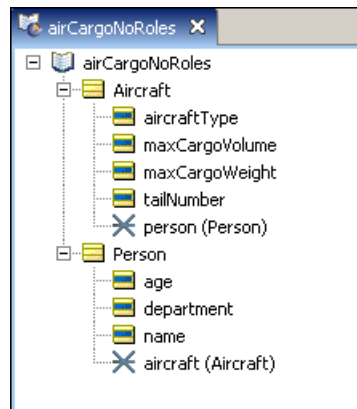

As shown in this class diagram, the entities `Person` and `Aircraft` are joined by an association. However, can this single association sufficiently represent multiple relationships between these entities? For example, a prior Fact Model might state that "a pilot flies an aircraft" and "a passenger rides in an aircraft" – both pilot and passenger are descendants of the entity `Person`. Furthermore, we can see that, in practice, some instances of `Person` may be pilots and some may be passengers. This is important because it suggests that some business rules may use `Person` in its pilot context, and others may use it in its passenger context. How do we represent this in the Vocabulary and rules we build in Corticon Studio?

Let's examine this problem in more detail. Assume we want to implement two new rules:

1. By FAA regulations, 747 aircraft must be flown by at least 2 pilots
2. A DC-10 may not carry more than 200 passengers

We call these rules "cross-entity" because they include more than one entity (both `Aircraft` and `Person`) in their expression. Unfortunately, with our Vocabulary as it is, we have no way to distinguish between pilots and passengers, so there is no way to unambiguously implement these 2 rules. This class diagram, when imported into Corticon Studio, looks like this:

**Figure 55: Vocabulary without Roles**

However, there are several ways to modify this Vocabulary to allow us to implement these rules. We will discuss these methods and examine the advantages and disadvantages of each.

## Use Inheritance

Use two separate entities for `Pilot` and `Passenger` instead of a single `Person` entity. This may often be the best way to distinguish between pilots and passengers, especially if the two types of `Person` reside in different databases or different database tables (an aspect of deployment that rule modelers may not be aware of). Also, if the two types of `Person` have some shared and some different attributes (`Pilot` may have attributes like `licenseRenewalDate` and `typeRating` while `Passenger` may have attributes like `farePaid` and `seatSelection`) then it may make sense to set up entities as descendants of a common ancestor entity (such as `Employee`).

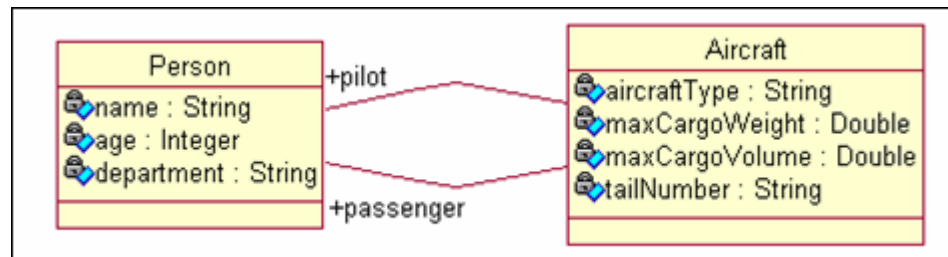

## Add an Attribute to Person

If the two types of person differ only in their type, then we may decide to simply add a `personType` (or similar) attribute to the entity. In some cases, `personType` will have the value of `pilot`, and sometimes it will have the value of `passenger`. The advantage of this method is that it is flexible: in the future, persons of type `manager` or `bag handler` or `air marshal` can easily be added. Also, this construction may be most consistent with the actual structure of the employee database or database table and maintains a normalized model. The disadvantage comes when the rule modeler needs to refer to a specific type of `Person` in a rule. While this can be accomplished using any of the filtering methods discussed in [Rule Writing Techniques](#), they are sometimes less convenient and clear than the final method, discussed next.

## Use Roles

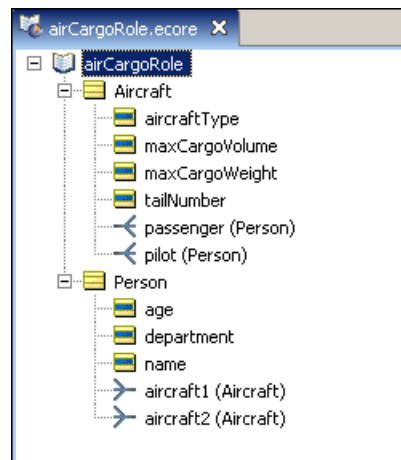

A role is a noun that labels one end of an association between two entities. For example, in our *Person-Aircraft* Vocabulary, the *Person* may have more than one role, or more than one kind of relationship, with *Aircraft*. An instance of *Person* may be a *pilot* or a *passenger*; each is a different role. To illustrate this in our UML class diagram, we add labels to the associations as follows:

**Figure 56: UML Class Diagram with Roles**

When the class diagram is imported into Corticon Studio, it appears as the Vocabulary below:

**Figure 57: Vocabulary with Roles**

Notice the differences between **Vocabulary with Roles** and **Vocabulary without Roles** – in **Vocabulary with Roles**, *Aircraft* contains 2 associations, one labeled `passenger` and the other `pilot`, even though both associations relate to the same *Person* entity. Also notice that we have updated the cardinalities of both *Aircraft*–*Person* associations to "one-to-many".

Written using roles, the first rule appears below. There are a few aspects of the implementation to note:

- Use of aliases for `Aircraft` and `Aircraft.pilot` (`plane` and `pilotOfPlane`, respectively). Aliases are just as useful for clarifying rule expressions as they are for shortening them.
- The rule Conditions evaluate data within the context of the `plane` and `pilotOfPlane` aliases, while the Action posts a message to the `plane` alias. This enables us to act on the `aircraft` entity based upon the attributes of its associated pilots. Note that Condition row b uses a special operator (`->size`) that "counts" the number of pilots associated with a plane. This is called a collection operator and is explained in more detail in the following chapters.

Figure 58: Rule #1 Implemented using Roles

Ref	ID	Post	Alias	Text
1		Violation	plane	Exactly 2 pilots are required to fly a 747 - fewer than 2 violates FAA regulations
2		Info	plane	Exactly 2 pilots are required to fly a 747 - 2 are assigned to this flight
3		Warning	plane	Exactly 2 pilots are required to fly a 747 - more than 2 is unnecessary but not unsafe

To demonstrate how Corticon Studio differentiates between entities based on rule scope, we will construct a new Ruletest that includes a single instance of `Aircraft` and 2 `Person` entities, neither of which has the role of pilot.

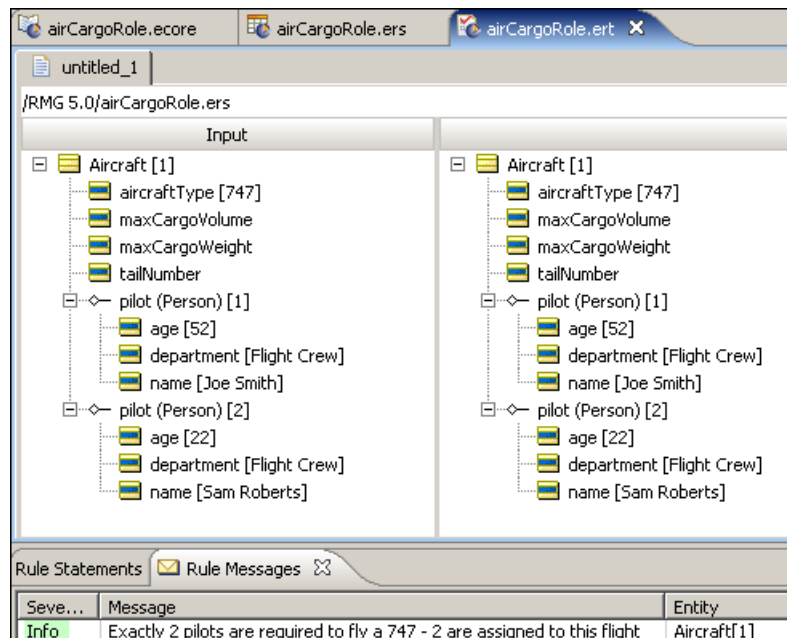

Figure 59: Ruletest with no `Person` entities in `Pilot` role

Severity	Message	Entity
Violation	Exactly 2 pilots are required to fly a 747 - fewer than 2 violates FAA regulations	Aircraft[1]

Despite the fact that there are two `Person` entities, both of whom are members of the `Flight Crew` department, the system recognizes that neither of them have the role of pilot (in relation to the `Aircraft` entity), and therefore generates the violation message shown.

If we create a new Input Ruletest, this time with both persons in the role of pilot, we see a different result, as shown:

**Figure 60: Ruletest with both `Person` entities in role of `Pilot`**

Finally, the rules are tested with one pilot and one passenger:

**Figure 61: Ruletest with one `Person` entity in each of `Pilot` and `Passenger` roles**

We see that despite the presence of two `Person` elements in the collection of test data, only one satisfies the rules' scope – `pilot` associated with `aircraft`. As a result, the rules determine that one pilot is insufficient to fly a 747, and the violation message is displayed.

These same concepts apply to the DC-10/Passenger business rule, which will not be implemented here.

## Technical aside

### Understanding Rule Associations and Scope as Relationships Between Tables in a Relational Database

Although it is not necessary for the rule modeler or developer to understand database theory, a business or systems analyst who is familiar with it may have already recognized that the preceding discussion of rule scope and context is an abstraction of basic relational concepts. Actual relational tables that contain the data for our Cargo example might look like the following:

**Figure 62: Tables in a Relational Database**

Aircraft		
tailNumber*	aircraftType	maxCargoWeight
N1001	747	200,000
N1002	747	200,000
N1003	DC-10	150,000

Cargo		
manifestNumber*	volume	weight
625A	300	100,000
625B	300	175,000
625C	300	150,000

FlightPlan		
flightNumber*	tailNumber	manifestNumber
101	N1001	625A
102	N1002	625B
103	N1003	625C

Each one of these tables has a column that serves as a unique identifier for each row (or *record*). In the case of the `Aircraft` table, the `tailNumber` is the unique identifier for each Aircraft record – this means that no two Aircraft can have the same `tailNumber`. `ManifestNumber` is the unique identifier for each `Cargo` record. These unique identifiers are known as "primary keys". Given the primary key, a particular record can always be found and retrieved. A common notation uses an asterisk character (\*) to indicate those table columns that serve as primary keys. If a Vocabulary has been connected to an external database using Enterprise Data Connector features, then you may notice asterisks next to attributes, indicating their designation as primary keys. See the *Corticon Server Integration and Deployment Guide*, *Direct Database Access* chapter for complete details.

Notice that the `FlightPlan` table contains columns that did not appear in our Vocabulary. Specifically, `tailNumber` and `manifestNumber` exist in the `Aircraft` and `Cargo` entities, respectively, but we did not include them in the `FlightPlan` Vocabulary entity. Does this mean that our original Vocabulary was wrong or incomplete? No - the extra columns in the `FlightPlan` table are really duplicate columns from the other two tables – `tailNumber` came from the `Aircraft` table and `manifestNumber` came from the `Cargo` table. These extra columns in the `FlightPlan` table are called *foreign keys* because they are the primary keys *from other tables*. They are the mechanism for creating relations in a relational database.

For example, we can see from the `FlightPlan` table that `flightNumber` 101 (the first row or record in the table) includes `Aircraft` of `tailNumber` N1001 and `Cargo` of `manifestNumber` 625A. The foreign keys in `FlightPlan` serve to link or connect a specific `Aircraft` with a specific `Cargo`. If the database is queried (using a query language like SQL, for example), a user could determine the weight of `Cargo` planned for `Aircraft` N1001 – by "traversing" the relationships from the `Aircraft` table to the `FlightPlan` table, we discover that `Aircraft` N1001 is scheduled to carry `Cargo` 625A. By traversing the `FlightPlan` table to the `Cargo` table, we discover that `Cargo` 625A weighs 100,000 lbs. Matching the foreign key in the `FlightPlan` table with the primary key in the `Cargo` table makes this traversal possible.

The Corticon Vocabulary captures this essential feature of relational databases, but abstracts it in a way that is friendlier to non-programmers. Rather than deal with concepts like foreign keys in our Vocabulary, we talk about "associations" between entities. Traversing an association in the Vocabulary is exactly equivalent to traversing a relationship between database tables. When we use a term like `Aircraft.tailNumber` in a rule, Studio creates a collection of `tailNumbers` from all records in the `Aircraft` table. This collection of data is then "fed" to the rule for evaluation. If however, the rule uses `FlightPlan.aircraft.tailNumber`, then Studio will create a collection of only those `tailNumbers` from the `Aircraft` table that have `FlightPlans` related to them – it identifies these aircraft instances by matching the `tailNumber` in the `Aircraft` table with the `tailNumber` (foreign key) in the `FlightPlan` table. If the `Aircraft` table contains 7 instances of aircraft (i.e., 7 unique rows in the table), but the `FlightPlan` table contains only 3 unique instances of flight plans, the term `FlightPlan.aircraft.tailNumber` will create a collection of only 3 tail numbers – those instances from the `Aircraft` table which have flight plans listed in the `FlightPlan` table. In database terminology, the scope of the rule determines how the tables are "joined".

When `FlightPlan` is used as the scope for our rule, Corticon Studio automatically ensures that the collection of data contains matching foreign keys. That's why, when we rewrote the rule using proper scope, the rule only fired 3 times – there are only 3 examples of `Aircraft-Cargo` combinations where the keys match. This also explains why, prior to using scope, the rule produced 6 spurious and irrelevant outcomes – 6 combinations of `Aircraft` and `Cargo` that were processed by the rule do not, in fact, exist in the `FlightPlan` table.

While the differences in processing requirements are not extreme in our simple example, for a large company like Federal Express, with a fleet of hundreds of aircraft and several thousand unique cargo shipments every day, the system performance differences could be enormous.

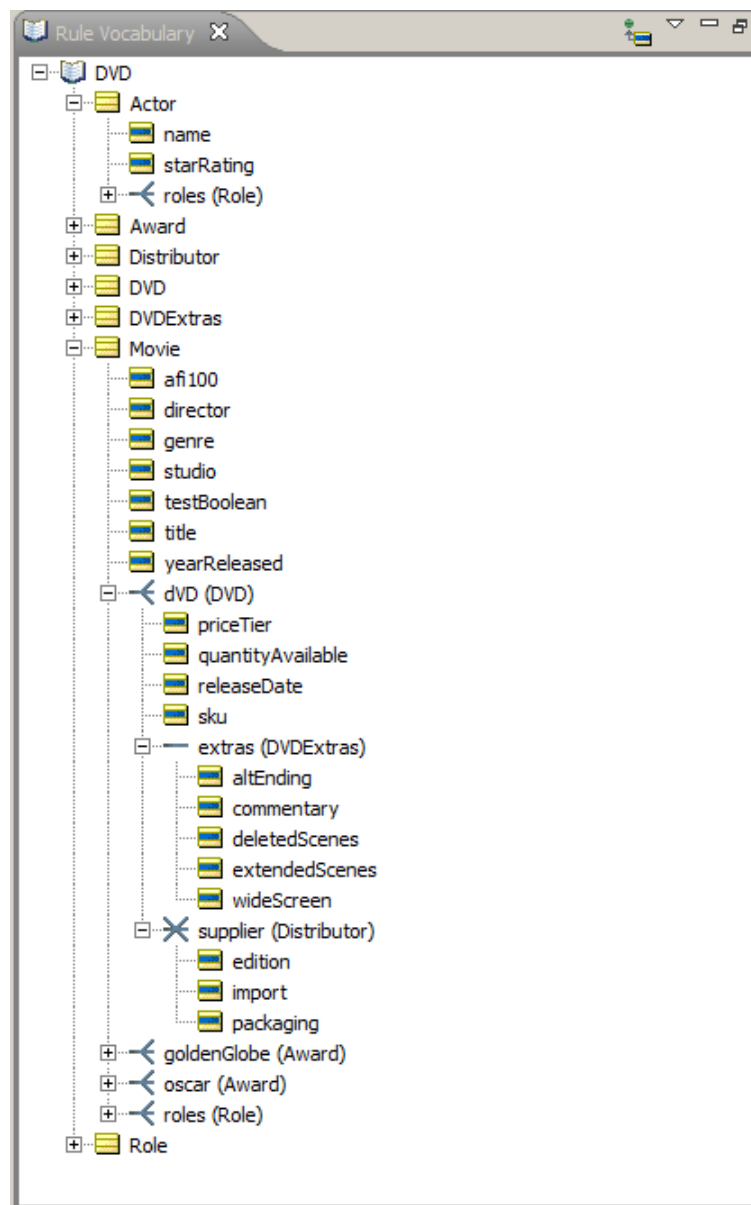

## Test yourself: Rule scope and context

---

**Note:** Try this test, and then go to **Answers:** [Rule scope & context](#) on page 281 to correct yourself.

---

Use the following Vocabulary to answer the next questions.

1. How many root-level entities are present in the Vocabulary?
2. Which of the following terms are allowed by the Vocabulary?

Movie.roles	Actor.roles	DVD.actor	Award.movie
-------------	-------------	-----------	-------------

3. Which of the following terms are **not** allowed by the Vocabulary?

Movie.oscar	Movie.supplier	Movie.roles.actor	Movie.dVD.extras
-------------	----------------	-------------------	------------------

4. Which Vocabulary term represents the following phrases?

- A movie's Oscars \_\_\_\_\_
- A movie's roles \_\_\_\_\_
- An actor's roles \_\_\_\_\_
- A DVD's distributor \_\_\_\_\_
- A movie's DVD extras \_\_\_\_\_
- An actor's Oscars \_\_\_\_\_

5. Which of the following terms represents the phrase "an actor in a role of a movie"

Movie.roles.dVD	Actor.roles.movie	DVD.actor.movie	Actor.movie.roles
-----------------	-------------------	-----------------	-------------------

6. Since the association between Actor and Role is bidirectional, we can use both Actor.roles and \_\_\_\_\_ in our rules.
7. Which two entities are associated with each other by more than one role?
8. What are the role names?
9. Besides roles, how else could these two relationships be represented in the Vocabulary to convey the same business meaning?
10. What is the advantage of using roles in this way?
11. When more than role is used to associate two entities, each role name must be:

friendly	unique	colorful	melifluous
----------	--------	----------	------------

12. True or False. Rules evaluate only data that shares the same scope
13. Write a conditional expression in a Rulesheet for each of the following phrases:
  - If a movie's DVD has deleted scenes...
  - If an actor played a role in a movie winning an Oscar...
  - If the DVD is an import...
  - If the Movie was released more than 50 years before the DVD...
  - If the actor ever played a leading role...
  - If the movie was nominated for a Golden Globe...

- If the Distributor offers any drama DVDs...

Given the rule "Disney animated classics are priced in the high tier", answer the following questions:

14. Which term should be used to represent Movie?
15. Which term should be used to represent DVD?
16. True or False. The following Rulesheet correctly relates the Movie and DVD entities?

Conditions		0	1
a	Movie.studio	-	'Disney'
b	Movie.genre	-	'Classic Animation'
c			
d			
e			
f			
g			
h			
Actions			
Post Message(s)			
A	DVD.priceTier		High
B			
C			
D			
E			
Overrides			

Ref	ID	Post	Alias	Text
1		Info	Movie	Disney animated classics are priced in the high tier

17. Given our business intent, how many times do we want the rule to fire given the Input Testsheet below?

18. Given the Ruletest Input above, how many times does the rule actually fire?

19. Assume we update the Rulesheet to include another rule, as shown below. Answer the following questions:

scope1Untitled_1.ers		0	1	2
Conditions				
a	Movie.studio	-	'Disney'	not {'Disney', 'MGM', 'BBC', 'PBS', 'Pixar'}
b	Movie.genre	-	'Classic Animation'	'Animation'
c				
d				
e				
f				
g				
h				
Actions				
Post Message(s)				
A	DVD.priceTier		High	Low
B				
C				
D				
E				
Overrides				
Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1		Info	Movie	Disney animated classics are priced in the high tier
2		Warning	Movie	Other animated movies are priced in the low tier

- Assuming the same Ruletest Input as question 57, what result do we *want* for Cinderella?
  - What result do we *want* for Toy Story?
  - What results do we *get* when the Test is executed?
  - How many times does *each* rule fire?
  - How many *total* rule firings occurred?
  - This set of combinations is called a \_\_\_\_\_
  - Does our result make business sense?
  - What changes should be made to the Rulesheet so that it functions as we intend?
20. True or False. Whenever our rules contain scope, we must define aliases in the Scope section of the Rulesheet.
21. Scope is another way of defining a specific \_\_\_\_\_ in the Vocabulary
22. If you change the spelling of an alias in the Scope section, then everywhere that alias is used in the Rulesheet will:

turn red	be deleted	be updated	be ignored
----------	------------	------------	------------

23. True or False. The spelling of an alias may be the same as the Vocabulary entity it represents?

## Rule writing techniques – logical equivalents

---

The Corticon Studio Rulesheet is a very flexible device for writing and organizing rules. It is often possible to express the same business rule multiple ways in a Rulesheet, with all forms producing the same logical results. Some common examples, as well as their advantages and disadvantages, are discussed in this chapter.

For details, see the following topics:

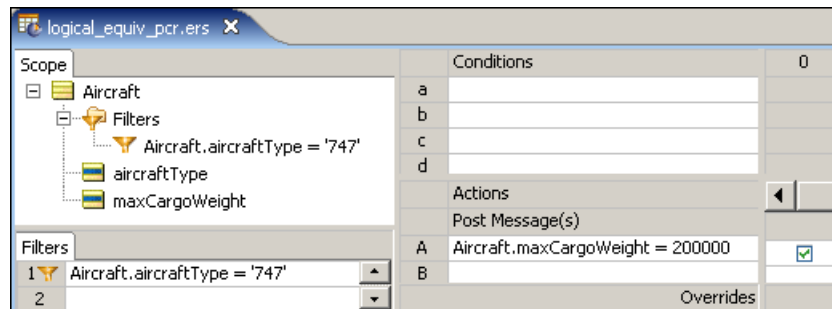

- [Filters vs. conditions](#)
- [Boolean condition Vs. values set](#)
- [Use of ranges in condition cells](#)
- [Alternatives to value ranges](#)
- [Standard boolean constructions](#)
- [Test yourself - questions – rule writing techniques – logical equivalents](#)

### Filters vs. conditions

The Filters section of a Rulesheet can contain one or more "master" conditional expressions for that Rulesheet. In other words, other business rules will fire if and only if data a) survives the Filter, and b) shares the same scope as the rules. Using our air cargo example from the previous chapter, we model the following rule:

1. A 747 has a maximum cargo weight of 200,000 lbs

**Figure 63: Rulesheet Using a Filter and Nonconditional Rule**

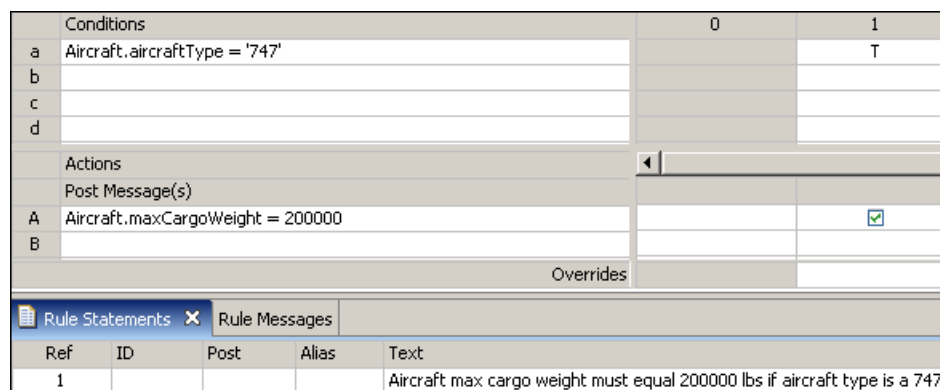

Here, the value of an Aircraft's `maxCargoWeight` attribute is assigned by column 0 in the Conditions/Actions pane (what we sometimes call a "Nonconditional" rule because it has no Conditions). The Filter acts as a master conditional expression because only Aircraft that satisfy the Filter - in other words, only those aircraft of `aircraftType = '747'`, successfully "pass through" to be evaluated by rule column 0, and are assigned a `maxCargoWeight` of 200,000. This effectively "filters out" all non-747 aircraft from evaluation by rule column 0.

If this Filter were not present, *all* Aircraft, regardless of `aircraftType`, would be assigned a `maxCargoWeight` of 200,000 lbs. Using this method, additional Rulesheets may be used to assign different `maxCargoWeight` values for each `aircraftType`. The Filter section may be thought of as a convenient way to quickly add the same conditional expression or constraint to all other rules in the same Rulesheet.

We can also achieve the same results without using Filters. The following figure shows how we use a Condition/Action rule to duplicate the results of the previous Rulesheet. The rule is restated as an "if-then" type of statement: "if the `aircraftType` is 747, then its `maxCargoWeight` equals 200,000 lbs".

**Figure 64: Rulesheet Using a Conditional Rule**

Regardless of how you choose to express logically equivalent rules in a Rulesheet, the results will also be equivalent

**Note:** While the logical result may be identical, the time required to produce those results may not be. See [Optimizing Rulesheets](#) in the Logical Validation chapter of this Guide for details.

That said, there may be times when it is advantageous to choose one way of expressing a rule over another, at least in terms of the visual layout, organization and maintenance of the business rules and Rulesheets. The example discussed in the preceding paragraphs was very simple because only one Action was taken as a result of the Filter or Condition. In cases where there are multiple Actions that depend on the evaluation of one or more Conditions, it may make the most sense to use the Filters section. Conversely, there may be times when using a Condition makes the most sense, such as the case where there are numerous values for the Condition that each require a different Action or set of Actions as a result. In our example above, there are different types of Aircraft in the company's fleet, and each has a different `maxCargoWeight` value assigned to it by rules. This could easily be expressed on one Rulesheet by using a single row in the Conditions section. It would require many Rulesheet s to express these same rules using the Filters section. This leads us to the next topic of discussion.

## Boolean condition Vs. values set

**Rulesheet Using a Conditional Rule** illustrates a simple Boolean Condition that evaluates to either `True` or `False`. The Action related to this Condition is either selected or not, on or off, meaning the value of `maxCargoWeight` is either assigned the value of `200,000` or it is not (Action statements are "activated" by selecting the check box that automatically appears when the cell is clicked). However, there is another way to express both Conditions and Actions using Values sets.

**Figure 65: Rulesheet Illustrating use of Multiple values in the same Condition Row**

Conditions		0	1	2	3
a	Aircraft.aircraftType		'DC-10'	'A340'	'747'
b					
c					
d					

Actions		0	1	2	3
A	Aircraft.maxCargoWeight		100000	150000	200000
B					

Ref	ID	Post	Alias	Text
A1				Aircraft max cargo weight must be 100000 when aircraft type is a DC-10
A2				Aircraft max cargo weight must be 150000 when aircraft type is an A340
A3				Aircraft max cargo weight must be 200000 when aircraft type is a 747

By using different values in the column cells of Condition and Action rows in **Rulesheet Illustrating use of Multiple values in the same Condition Row**, we can write multiple rules (represented as different columns in the table) for different Condition-Action combinations. Expressing these same rules using Boolean expressions would require many more Condition and Action rows, and would fail to take advantage of the semantic pattern these three rules share.

## Exclusionary syntax

The following examples are also logically equivalent:

**Figure 66: Exclusionary Logic Using Boolean Condition, Pt. 1**

The screenshot shows the 'airCargo.ecore' rule editor. The 'Conditions' section has a table with two columns, 0 and 1. Row 'a' contains the condition 'Aircraft.aircraftType <> '747'' with values 0 and 'T'. Row 'b' is empty. The 'Actions' section has a table with two columns, 0 and 1. Row 'A' contains the action 'Aircraft.maxCargoWeight = 100000' with values 0 and a checked checkbox. Row 'B' is empty. The 'Overrides' section is empty. The 'Rule Messages' section shows a table with columns Ref, ID, Post, Alias, and Text. Row 1 has Ref '1', ID 'Info', Post 'Aircraft', and Text 'Aircraft max cargo weight must be 100,000 when aircraft type is NOT a 747'.

Conditions		0	1
a	Aircraft.aircraftType <> '747'		T
b			
-			
Actions		0	1
Post Message(s)			
A	Aircraft.maxCargoWeight = 100000		<input checked="" type="checkbox"/>
B			
-			
Overrides			

Ref	ID	Post	Alias	Text
1	Info	Aircraft		Aircraft max cargo weight must be 100,000 when aircraft type is NOT a 747

**Figure 67: Exclusionary Logic Using Boolean Condition, Pt. 2**

The screenshot shows the 'airCargo.ecore' rule editor. The 'Conditions' section has a table with two columns, 0 and 1. Row 'a' contains the condition 'Aircraft.aircraftType = '747'' with values 0 and 'F'. Row 'b' is empty. The 'Actions' section has a table with two columns, 0 and 1. Row 'A' contains the action 'Aircraft.maxCargoWeight = 100000' with values 0 and a checked checkbox. Row 'B' is empty. The 'Overrides' section is empty. The 'Rule Messages' section shows a table with columns Ref, ID, Post, Alias, and Text. Row 1 has Ref '1', ID 'Info', Post 'Aircraft', and Text 'Aircraft max cargo weight must be 100,000 when aircraft type is NOT a 747'.

Conditions		0	1
a	Aircraft.aircraftType = '747'		F
b			
-			
Actions		0	1
Post Message(s)			
A	Aircraft.maxCargoWeight = 100000		<input checked="" type="checkbox"/>
B			
-			
Overrides			

Ref	ID	Post	Alias	Text
1	Info	Aircraft		Aircraft max cargo weight must be 100,000 when aircraft type is NOT a 747

**Figure 68: Exclusionary Logic Using Negated Value**

The screenshot shows the 'airCargo.ecore' rule editor. The 'Conditions' section has a table with two columns, 0 and 1. Row 'a' contains the condition 'Aircraft.aircraftType' with values 0 and 'not '747''. Row 'b' is empty. The 'Actions' section has a table with two columns, 0 and 1. Row 'A' contains the action 'Aircraft.maxCargoWeight = 100000' with values 0 and a checked checkbox. Row 'B' is empty. The 'Overrides' section is empty. The 'Rule Messages' section shows a table with columns Ref, ID, Post, Alias, and Text. Row 1 has Ref '1', ID 'Info', Post 'Aircraft', and Text 'Aircraft max cargo weight must be 100,000 when aircraft type is NOT a 747'.

Conditions		0	1
a	Aircraft.aircraftType		not '747'
b			
-			
Actions		0	1
Post Message(s)			
A	Aircraft.maxCargoWeight = 100000		<input checked="" type="checkbox"/>
B			
-			
Overrides			

Ref	ID	Post	Alias	Text
1	Info	Aircraft		Aircraft max cargo weight must be 100,000 when aircraft type is NOT a 747

Notice that that the last example uses the unary function `not`, described in more detail in the *Rule Language Guide*, to negate the value `747` selected from the Values set.

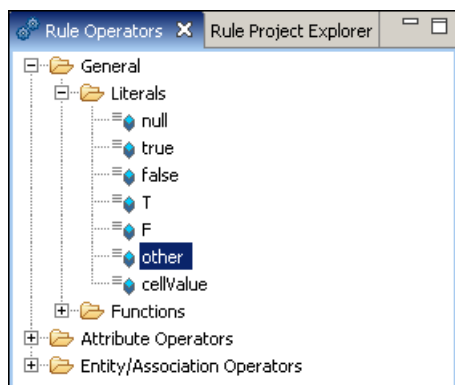

Once again we see that the same rule can be expressed in different ways on the Rulesheet, with identical results. It is left to the rule modeler to decide which way of expressing the rule is preferable in a given situation. We recommend, however, avoiding double negatives. Most people find it easier to understand `attribute=T` instead of `attribute<>F`, even though logically the two expressions are equivalent

**Note:** This assumes bi-value logic. If tri-value logic is assumed (such as, for a non-mandatory attribute), meaning the null value is available in addition to true and false, then these two expressions are not equivalent. If `attribute = null`, then the truth value of `attribute<>F` is true while that of `attribute=T` is false.

## Using "other" in condition cells

Sometimes it is easier to define values we don't want matched than it is to define those we do. In the example shown above in [Exclusionary Logic Using Negated Value](#), we specify a `maxCargoWeight` to assign when `aircraftType` is *not* a 747. But what would we write in the Conditions Cell if we wanted to specify any `aircraftType` *other than* those specified in *any of the other* Conditions Cells? For this, we use a special term in the Operator Vocabulary named `other`, shown in the following figure:

Figure 69: Literal Term `other` in the Operator Vocabulary

The term `other` provides a simple way of specifying any value *other than* any of those specified in other Cells of the same Conditions row. The following figure illustrates how we can use `other` in our example.

**Figure 70: Rulesheet Using `other` in a Condition Cell**

Conditions		0	1	2	3	4
a	Aircraft.aircraftType		'DC-10'	'A340'	'747'	other
b						
c						
Actions						
Post Message(s)						
A	Aircraft.maxCargoWeight		100000	150000	200000	50000
B						
Overrides						

Ref	ID	Post	Alias	Text
1				Aircraft max cargo weight equals 100,000 lbs when the aircraft is a DC-10
2				Aircraft max cargo weight equals 150,000 lbs when the aircraft is an A340
3				Aircraft max cargo weight equals 200,000 lbs when the aircraft is a 747
4				Aircraft max cargo weight equals 50,000 lbs for all other aircraft types

Here, we added a new rule (column 4) that assigns a `maxCargoWeight` of 50000 to any `aircraftType` *other than* the specific values identified in the cells in Condition row a (for example, a 727 ). Our Rulesheet is now complete because all possible Condition-Action combinations are explicitly defined by columns in the decision table.

## Use of ranges in condition cells

When using values in Condition Cells for attributes of any data type except Boolean, the values do not need to be discreet – they may be in the form of a range. A value range is typically expressed in the following format: `x..y`, where `x` and `y` are the starting and ending values for the range *inclusive* of the endpoints if there is no other notation to indicate otherwise. This is illustrated in the following figure:

**Figure 71: Rulesheet Using Value Ranges in the Column Cells of a Condition Row**

Conditions		0	1	2	3	4
a	FlightPlan.flightNumber		<=100	101..200	201..300	>300
b						
c						
Actions						
Post Message(s)						
A	FlightPlan.aircraft.maxCargoWeight		50000	100000	150000	200000
Overrides						

Ref	ID	Post	Alias	Text
1				Aircraft max cargo weight must be 50000 when flight number is less than or equal to 100
2				Aircraft max cargo weight must be 100000 when flight number is between 101 and 200, inclusive
3				Aircraft max cargo weight must be 150000 when flight number is between 201 and 300, inclusive
4				Aircraft max cargo weight must be 200000 when flight number is greater than 300

In this example, we are assigning a `maxCargoWeight` value to each `Aircraft` depending on the `flightNumber` value from the `FlightPlan` that the `Aircraft` is associated with. The value range `101..200` represents all values (Integers in this case) between 101 and 200, including the range "endpoints" 101 and 200. This is an inclusive range in that the starting and ending values are included in the range.

Corticon Studio also gives you the option of defining value ranges where one or both of the endpoints are "exclusive", meaning that they are **not** included in the range of values – this is the same idea as the difference between "greater than" and "greater than or equal to". The following figure, **Rulesheet Using Open-Ended Value Ranges in Condition Cells**, shows the same Rulesheet shown in the previous figure, but with one difference: we have changed the value range `201..300` to `(200..300]`. The starting parenthesis `(` indicates that the starting value for the range, 200, is exclusive – it is **not** included in the range. The ending bracket `]` indicates that the ending value is inclusive. Since `flightNumber` is an Integer value and there are therefore no fractional values allowed, `201..300` and `(200..300]` are equivalent.

**Figure 72: Rulesheet Using Open-Ended Value Ranges in Condition Cells**

Conditions		0	1	2	3	4
a	FlightPlan.flightNumber		<=100	101..200	(200..300]	>300
b						
c						
Actions						
Post Message(s)						
A	FlightPlan.aircraft.maxCargoWeight		50000	100000	150000	200000
Overrides						

Ref	ID	Post	Alias	Text
1				Aircraft max cargo weight must be 50000 when flight number is less than or equal to 100
2				Aircraft max cargo weight must be 100000 when flight number is between 101 and 200, inclusive
3				Aircraft max cargo weight must be 150000 when flight number is between 201 and 300, inclusive
4				Aircraft max cargo weight must be 200000 when flight number is greater than 300

Listed below are all of the possible combinations of parenthesis and bracket notation for value ranges and their meanings:

**Figure 73: Rulesheet Using Open-Ended Value Ranges in Condition Cells**

`(x..y)` - is the range between `x` & `y`, excluding both `x` & `y`  
`(x..y]` - is the range between `x` & `y`, excluding `x` and including `y`  
`[x..y)` - is the range between `x` & `y`, including `x` and excluding `y`  
`[x..y]` - is the range between `x` & `y`, including both `x` & `y`

As illustrated in columns 2-3 of **Rulesheet Using Value Ranges in the Column Cells of a Condition Row** and column 2 of **Rulesheet Using Open-Ended Value Ranges in Condition Cells**, if a value range has no enclosing parentheses or brackets, it is assumed to be inclusive. It is therefore not necessary to use the `[..]` notation for a closed range in Corticon Studio; in fact, if you try to create a value range with `[..]` in Corticon Studio, the square brackets will be automatically removed. However, should either end of a value range have a parenthesis or a bracket, then the other end must also have a parenthesis or a bracket. For example, `x..y)` is not allowed, and is properly expressed as `[x..y)`.

Value ranges can also be used in the Filters section of the Rulesheet. See the *Rule Language Guide's Special Syntax* chapter for full details on usage.

## Alternatives to value ranges

As you might expect, there is another way to express a rule which contains a range of values. One alternative is to use a series of Boolean Conditions that cover the ranges of concern. This is illustrated in the following figure:

**Figure 74: Rulesheet Using Boolean Conditions to Express Value Ranges**

The screenshot shows a rulesheet titled 'BooleansAsValueRanges.ers'. It features a table with columns for conditions (a, b, c) and five value ranges (0, 1, 2, 3, 4). Conditions a, b, and c are 'FlightPlan.flightNumber > 100', '> 200', and '> 300' respectively. The table shows that for range 0, all conditions are false (F). For range 1, condition a is false and b and c are true (T). For range 2, conditions a and b are false and c is true. For range 3, conditions a and b are true and c is false. For range 4, all conditions are true. Below the conditions table is an 'Actions' section with a single action 'A' that sets 'FlightPlan.aircraft.maxCargoWeight' to 50,000 lbs. At the bottom, the 'Rule Statements' section lists four rules (A1-A4) corresponding to the value ranges, each with a text description of the cargo weight constraint.

Conditions	0	1	2	3	4
a FlightPlan.flightNumber > 100		F	T	T	T
b FlightPlan.flightNumber > 200		F	F	T	T
c FlightPlan.flightNumber > 300		F	F	F	T

Ref	ID	Post	Alias	Text
A1				Aircraft max cargo weight must be 50,000 lbs when flight number is less than or equal to 100
A2				Aircraft max cargo weight must be 100,000 lbs when flight number is between 101 and 200, inclusive
A3				Aircraft max cargo weight must be 150,000 lbs when flight number is between 201 and 300, inclusive
A4				Aircraft max cargo weight must be 200,000 lbs when flight number is greater than 300

The rules here are identical to the rules in [Rulesheet Using Value Ranges in the Column Cells of a Condition Row](#) and [Rulesheet Using Open-Ended Value Ranges in Condition Cells](#), but are expressed using a series of three Boolean Conditions. Recall that in a decision table, values aligned vertically in the same column represent **AND** 'ed Conditions in the rule. So rule 1, as expressed in column 1, reads:

if `flightNumber` is not greater than 100 and `flightNumber` is not greater than 200 and `flightNumber` is not greater than 300, then its `maxCargoWeight` must equal 50,000 lbs.

Expressing this rule in friendlier, more natural English, we might say:

An Aircraft's max cargo weight must be 50,000 lbs when flight number is less than or equal to 100.

This is how the rule is expressed in the **Rule Statements** section in [Rulesheet Using Boolean Conditions to Express Value Ranges](#). The same rules may also be expressed using a series of Rulesheets with the applicable range of `flightNumber` values constrained by Filters. Corticon Studio gives you the flexibility to express and organize your rules any number of possible ways – as long as the rules are logically equivalent, they will produce identical results when executed.

In the case of rules involving numeric value ranges as opposed to discrete numeric values, the value range option allows you to express your rules in a very simple and elegant way. It is especially useful when dealing with Decimal type values.

## Standard boolean constructions

A decision table is a graphical method of organizing and formalizing logic. But if you have a background in computer science or formal logic, you may have seen alternative methods. One such method is called a truth table.

# Test yourself - questions – rule writing techniques – logical equivalents

**Note:** Try this test, and then go to **Answers:** [Rule writing techniques – logical equivalents](#) on page 283 to correct yourself.

- Filters act as master rules for all other rules in the same Rulesheet that share the same \_\_\_\_\_.
- An expression that evaluates to a True or False value is called a \_\_\_\_\_ expression.
- True or False. Condition row values sets must be complete.
- True or False. Action row values sets must be complete.
- The special term \_\_\_\_\_ can be used to complete any Condition row values set.
- What operator is used to negate a Boolean expression?
- If a Boolean expression is written in a Condition row, what values are automatically entered in the Values set when **Enter** is pressed?
- A Filter expression written as `Entity.boolean1=T` is equivalent to (circle all that apply)

<code>Entity.boolean1</code>	<code>Entity.boolean1&lt;&gt;F</code>	<code>Entity.boolean1=F</code>	<code>not (Entity.boolean1=F)</code>
------------------------------	---------------------------------------	--------------------------------	--------------------------------------

- Of all alternatives listed in Question 71, which is the best choice? Why?
- Describe the error (if any) in each of the following value ranges. Assume all are used in Conditions values sets.
  - `{1..10, other}`
  - `{1..a, other}`
  - `{'a'..other}`
  - `{1..10, 5..20, other}`
  - `{1..10, [10..20), other}`
  - `{'red', 'green', 'blue'}`
  - `{<0, 0..15, >3}`
- True or False. The special term `other` may be used in Action row values sets.
- Using best practices discussed in this chapter, model the following rules on a single Rulesheet:
  - If the part is in stock and it has a blue tag, then the part's discount is 10%
  - If the part is in stock and it has a red tag, then the part's discount is 15%
  - If the part is in stock and it has a yellow tag, then the part's discount is 20%
  - If the part is in stock and it has a green tag, then the part's discount is 25%
  - If the part is in stock and it has any other color tag, then the part's discount is 5%

- 13. True or False. A Nonconditional rule is equivalent to an Action expression with no Condition.
- 14. True or False. A Nonconditional rule is governed by any Preconditions on the same Rulesheet.

---

# Collections

---

Collections enable operations to be performed on a set of instances specified by an alias. For details, see the following topics:

- [Understanding how Corticon Studio handles collections](#)
- [Visualizing collections](#)
- [A basic collection operator](#)
- [Filtering collections](#)
- [Using aliases to represent collections](#)
- [Sorted aliases](#)
- [Singletons](#)
- [Special collection operators](#)
- [Aggregations that optimize database access](#)
- [Test yourself - questions – collections](#)

## Understanding how Corticon Studio handles collections

Support for using collections is extensive in Corticon Studio – in fact, the integration of collection support in the Rules Language is so seamless and complete, the rule modeler will often discover that rules are performing multiple evaluations on collections of data beyond what he/she anticipated! This is partly the point of a declarative environment – the rule modeler need only be concerned with *what* the rules do, rather than *how* they do it. How the system actually iterates or cycles through all the available data during rule execution should not be of concern.

As we saw in previous examples, a rule with term `FlightPlan.aircraft` was evaluated for every instance of `FlightPlan.aircraft` data delivered to the rule, either by an XML message or by a Ruletest (which are really the same thing, as the Ruletest simply serves as a quick and convenient way to create XML payloads and send them to the rules). A rule is expressed in Corticon Studio the same way regardless of how many instances of data are to be evaluated by it – contrast this to more traditional *procedural* programming techniques, where "for-do" or "while-next" type looping syntax is often required to ensure all relevant data is evaluated by the logic.

## Visualizing collections

Collections of data may be visualized as discrete portions, subsets, or "branches" of the Vocabulary tree – a "parent" entity associated with a set of "child" entities, which we call *elements* of the collection. Looking back at the [role example](#) from a previous chapter, the collection of pilots can be illustrated as:

**Figure 75: Visualizing a Collection of Pilots**

In this figure, the `aircraft` entity is the parent of the collection, while each `pilot` is a child element of the collection. As we saw in the role example, this collection is expressed as `aircraft.pilot` in the Corticon Rule Language. It is important to reiterate that this collection contains scope – we are seeing the collection of pilots as they relate to this aircraft. Or, put more simply, we are seeing a plane and its 2 pilots, arranged in a way that is consistent with our Vocabulary. Whenever a rule exists that contains or uses this same scope, it will also *automatically* evaluate this collection of data. And if there are multiple collections with the same scope (for example, several aircraft, each with its own collection of pilots), then the rule will automatically evaluate all those collections, as well. In our lexicon, "evaluate" has a different meaning than "fire". *Evaluate* means that a rule's scope and Conditions will be compared to the data to see if they are satisfied. If they are satisfied, then the rule *fires* and its Actions are executed.

Collections can be much more complex than this simple pilot example. For instance, a collection can comprise more than one type or "level" of association:

**Figure 76: 3-Level Collection**

This collection is expressed as `parent.child.grandchild` in the Corticon Rule Language. Now let's look at a simple collection operator and understand how it works given the collection in **Visualizing a Collection of Pilots**.

---

**Note:** The "parent" and "child" nomenclature is a bit arbitrary. Assuming bidirectional associations, a child from one perspective could also be a parent in another.

---

## A basic collection operator

As an example, let's use the `->size` operator (see the *Rule Language Guide* for more about this operator). This operator returns the number of elements in the collection that it follows in a rule expression. Using the collection from [Visualizing a Collection of Pilots](#):

```
aircraft.pilot -> size
```

returns the value of 2. In the expression:

```
aircraft.crewSize = aircraft.pilot -> size
```

`crewSize` (assumed to be an attribute of `Aircraft`) is assigned the value of 2.

Corticon Studio requires that all rules containing collection operators use unique aliases to represent the collections. [Using aliases to represent collections](#) is described in greater detail in this chapter. A more accurate expression of the rule above becomes:

```
plane.pilot -> size
```

or

```
plane.crewsize = plane.pilot -> size
```

where `plane` is an alias for the collection of `pilots` on `aircraft`.

## Filtering collections

The process of screening specific elements from a collection is known as "filtering", and the Corticon Studio supports filtering by a special use of Filter expressions. See the [Filters & Preconditions](#) topic for more details.

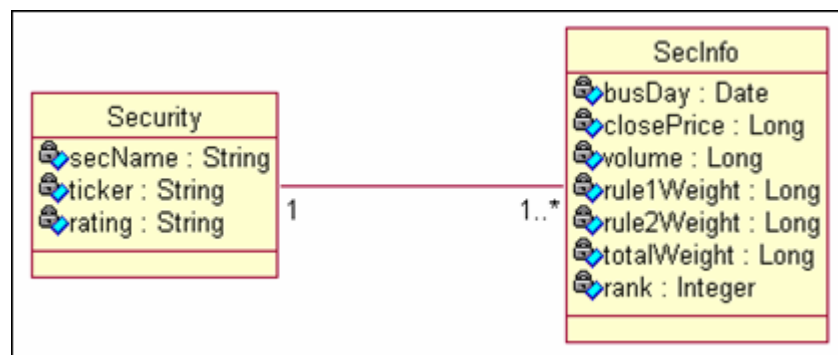

## Using aliases to represent collections

Aliases provide a means of using scope to specify elements of a collection; more specifically, we are using aliases (expressed or declared in the Scope section of the Rulesheet) to represent *copies* of collections. This concept is important because aliases give you the ability to operate on and compare multiple collections, or even copies of the same collection. There are situations where such operations and comparisons are required by business rules. Such rules are not easy (and sometimes not possible) to implement without using aliases.

**Note:** To ensure that the system knows precisely which collection (or copy) you are referring to in your rules, it is necessary to use a **unique alias** to refer to each collection.

For the purposes of illustration, we will introduce a new scenario and business Vocabulary. This new scenario involves a financial services company that compares and ranks stocks based on the values of attributes such as closing price and volume. A model for doing this kind of ranking can get very complex in real life; however, we will keep our example simple. Our new Vocabulary is illustrated in a UML class diagram in the following figure:

**Figure 77: Security Vocabulary UML Class Diagram**

This Vocabulary consists of only two entities:

**Security** – represents a security (stock) with attributes like security name (`secName`), ticker symbol, and `rating`.

**SecInfo** – is designed to record information for each stock for each business day (`busDay`); attributes include values recorded for each stock (`closePrice` and `volume`) and values determined by rules (`totalWeight` and `rank`) each business day.

The association between **Security** and **SecInfo** is `1..*` (one-to-many) since there are multiple instances of **SecInfo** data (multiple days of historical data) for each **Security**.

In our scenario, we will use three rules to determine a security's rank:

1. A security whose closing price today is higher than its closing price on the previous business day must have a value of 0.5 assigned to its rule 1 weight; otherwise, a value of 0 must be assigned to its rule 1 weight.
2. A security whose trading volume today is greater than its trading volume on the previous business day must have a value of 0.25 assigned to its rule 2 weight; otherwise, a value of 0 must be assigned to its rule 2 weight.
3. A security's total weight is equal to the sum of its rule 1 weight and its rule 2 weight.

Finally, rules will be used to assign a rank based on the total weight. It is interesting to note that although the rules refer to a security's closing price, volume, and rule weights, these attributes are actually properties of the `SecInfo` entity. Rulesheets that accomplish these tasks are shown in the next two figures.

**Figure 78: Rulesheet with Ranking Model Rules 1 and 2**

	0	1	2	3	4
a		T	F	-	-
b		-	-	T	F
c					
A		0.5	0		
B				0.25	0
Overrides					

Ref	ID	Post	Alias	Text
1		Info	sec	If today's closing price > last business day's closing price, then rule 1 weight = 0.5
2		Info	sec	If today's closing price <= last business day's closing price, then rule 1 weight = 0
3		Info	sec	If today's closing volume > last business day's closing volume then rule 2 weight = 0.25
4		Info	sec	If today's closing volume <= last business day's closing volume then rule 2 weight = 0

In the figure above, we see two business rules expressed in a total of four rule models (one for each possible outcome of the two business rules). The rules themselves are straightforward, but the shortcuts (alias values) used in these rules are different than any we have seen before. In the Scope section, we see the following:

**Figure 79: Close-up of the Scope Section from Rulesheet with Ranking Model Rules 1 and 2**

```

Scope
├── Security <sec>
│   ├── Filters
│   ├── secInfo <secinfo1>
│   └── secInfo <secinfo2>
  
```

`Security` is the scope for our Rulesheet, which is not a new concept. But then we see that there are two aliases for the `SecInfo` entities associated with `Security`: `secinfo1` and `secinfo2`. Each of these aliases represents a separate but identical collection of the `SecInfo` entities associated with `Security`. In this Rulesheet, we constrain each alias by using Filters; in a later example, we will see how more loosely constrained aliases can represent many different elements in a collection when the Corticon Server evaluates rules. In this specific example, though, one instance of `SecInfo` represents the current business day (`today`) and the other instance represents the previous business day (`today.addDays(-1)`).

**Note:** For details on the `.addDays` operator, refer to that topic in the *Rule Language Guide*.

Once the aliases are created and constrained, we can use them in our rules where needed. In the figure **Rulesheet with Ranking Model Rules 1 and 2**, we see that the use of aliases in the Conditions section allows comparison of `closePrice` and `volume` values from one specific `SecInfo` element (the one with today's date) of the collection with another (the one with yesterday's date).

The following figure shows a second Rulesheet which uses a Nonconditional rule to calculate the sum of the partial weights from our model rules as determined in the first Rulesheet, and Conditional rules to assign a rank value between 1 and 4 to each security based on the sum of the partial weights. Since we are only dealing with data from the current day in this Rulesheet (as specified in the Filters), only one instance of `SecInfo` per `Security` applies and we do not need to use aliases.

**Figure 80: Rulesheet with Total Weight Calculation and Rank Determination**

The screenshot shows the Corticon Rulesheet Editor for a rulesheet named `secInfo2.ers`. The **Scope** pane on the left shows a hierarchy: `Security [sec]` containing `Filters` and `secInfo [secInfo]`. The **Filters** section contains two filters: `1 secInfo.busDay = today` and `2` (empty). The **Conditions** section has two conditions: `a secInfo.totalWeight` and `b` (empty). The **Actions** section has two actions: `A secInfo.totalWeight = secInfo.rule1Weight + secInfo.rule2Weight` and `B secInfo.rank`. The **Rule Statements** table at the bottom lists the following statements:

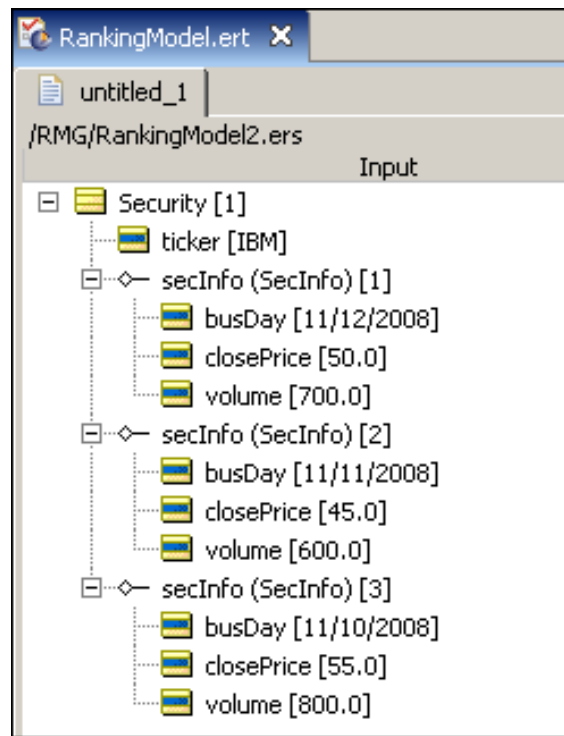

Ref	ID	Post	Alias	Text
0		Info	sec	Total weight = sum of rule 1 weight and rule 2 weight
1		Info	sec	If total weight = 0, then rank = 1
2		Info	sec	If total weight = 0.25, then rank = 2
3		Info	sec	If total weight = 0.5, then rank = 3
4		Info	sec	If total weight = 0.75, then rank = 4

We can test our new rules using a Ruleflow to combine the two Rulesheets. In a Ruletest which executes the Ruleflow, we would expect to see the following results:

1. The `Security.secInfo` collection that contains data for the current business day (we expect that this collection will reduce to just a single `secinfo` element, since only one `secinfo` element exists for each day) should be assigned to alias `secinfo1` for evaluating the model rules.
2. The `SecInfo` instance that contains data for the previous business day (again, the collection filters to a single `secinfo` element for each `Security`) should be assigned to alias `secinfo2` for evaluating the model rules.
3. The partial weights for each rule, sum of partial weights, and resulting rank value should be assigned to the appropriate attributes in the current business day's `SecInfo` element.

A Ruleflow constructed for testing the ranking model rules is as shown:

**Figure 81: Ruletest for Testing Security Ranking Model Rules**

In this figure, we have added one `Security` object and three associated `SecInfo` objects from the Vocabulary. The current day at the time of the Ruletest is 11/12/2008, so the three `SecInfo` objects represent the current business day and two previous business days. The third business day is included in this Ruletest to verify that the rules are using only the current and previous business days – none of the data from the third business day should be used if the rules are executing correctly. Based on the values of `closePrice` and `volume` in our two `SecInfo` objects being tested, we expect to see the highest rank of 4 assigned to our security in the current business day's `SecInfo` object.

Figure 82: Ruletest for Security Ranking Model Rules

The screenshot displays the Ruletest interface for the Security Ranking Model Rules. It is divided into two main sections: Input and Output, each showing a hierarchical tree of data. Below these is a tabbed interface with 'Rule Statements' and 'Rule Messages' (selected). The 'Rule Messages' tab shows a table of messages.

**Input Tree:**

- Security [1]
  - ticker [IBM]
  - secInfo (SecInfo) [1]
    - busDay [11/12/2008]
    - closePrice [50.0]
    - volume [700.0]
  - secInfo (SecInfo) [2]
    - busDay [11/11/2008]
    - closePrice [45.0]
    - volume [600.0]
  - secInfo (SecInfo) [3]
    - busDay [11/10/2008]
    - closePrice [55.0]
    - volume [800.0]

**Output Tree:**

- Security [1]
  - ticker [IBM]
  - secInfo (SecInfo) [1]
    - busDay [11/12/2008]
    - closePrice [50.000000]
    - rank [4]
    - rule1Weight [0.500000]
    - rule2Weight [0.250000]
    - totalWeight [0.750000]
    - volume [700.000000]
  - secInfo (SecInfo) [2]
    - busDay [11/11/2008]
    - closePrice [45.000000]
    - volume [600.000000]
  - secInfo (SecInfo) [3]
    - busDay [11/10/2008]
    - closePrice [55.000000]
    - volume [800.000000]

**Rule Messages Table:**

Sev...	Message	Entity
Info	If today's closing price > last business day's closing price, then rule 1 weight = 0.5	Security[1]
Info	If today's closing volume > last business day's closing volume then rule 2 weight = 0.25	Security[1]
Info	Total weight = sum of rule 1 weight and rule 2 weight	Security[1]
Info	If total weight = 0.75, then rank = 4	Security[1]

We see the expected results produced above. Both `closePrice` and `volume` for 11/12/2008 were higher than the values for those same attributes on 11/11/2008; therefore, both `rule1Weight` and `rule2Weight` attributes were assigned their "high" values by the rules. Accordingly, the `totalWeight` value calculated from the sum of the partial weights was the highest possible value and a `rank` of 4 was assigned to this security for the current day.

As previously mentioned, the example above was tightly constrained in that the aliases were assigned to two very specific elements of the referenced collections. What about the case where there are multiple instances of an entity that you would like to evaluate with your rules? We will discuss just such an example next.

Our second example is also based on our security ranking scenario but, in this example, the rank assignment that was accomplished will be done in a different way. Instead, we would like to rank a number of securities based on their relative performance to one another, rather than against a preset ranking scheme like the one in [Figure 78](#) on page 93. In the rules for our new example, we will compare the `totalWeight` value that is determined for each security for the current business day against the `totalWeight` of every other security, and determine a `rank` based on this comparison of `totalWeight` values. A Rulesheet for this alternate method of ranking securities is shown in the next figure.

**Figure 83: Rulesheet with Alternate Rank Determination Rules**

The screenshot shows the Corticon Rulesheet Editor for a rulesheet named 'AlternateRank.ers'. The interface is divided into several sections:

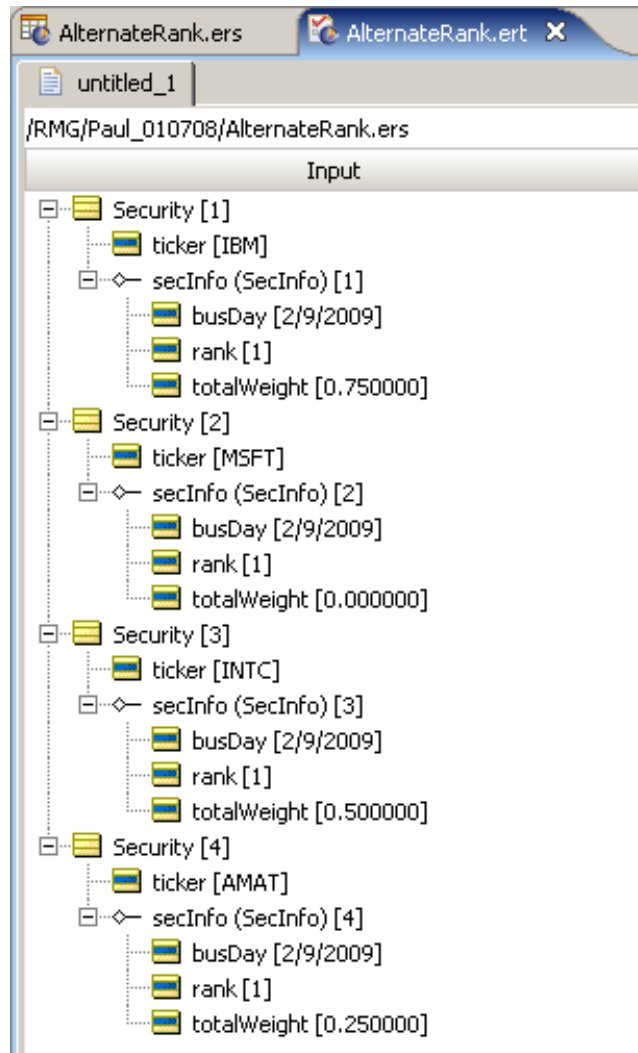

- Scope:** A tree view on the left showing the hierarchy of objects: Security [sec1], Filters, ticker, secInfo [secinfo1], Security [sec2], Filters, ticker, and secInfo [secinfo2].
- Conditions:** A table with columns 'Conditions', '0', '1', and '2'. Row 'a' contains the condition 'secinfo1.totalWeight > secinfo2.totalWeight' with values '-', 'T', and 'F' respectively. Rows 'b' through 'q' are empty.
- Actions:** A table with columns 'Actions' and 'Post Message(s)'. Row 'A' contains the action 'secinfo1.rank += 1' with a checked checkbox in the 'Post Message(s)' column. Rows 'B' through 'E' are empty.
- Filters:** A list of filters on the left:
  - 1 sec1 <> sec2
  - 2 secinfo1.busDay = today
  - 3 secinfo2.busDay = today
  - 4
  - 5
- Rule Statements:** A table at the bottom with columns 'Ref', 'ID', 'Post', 'Alias', and 'Text'.
 

Ref	ID	Post	Alias	Text
1		Info		If Security 1 [{sec1.ticker}] total weight > Security 2 [{sec2.ticker}] total weight, then increment [{sec1.ticker}] rank by 1
2		Info		If Security 1 [{sec1.ticker}] total weight <= Security 2 [{sec2.ticker}] total weight, then take no action

In these new ranking rules, we have created aliases to represent specific instances of `Security` and their associated collections of `SecInfo`. As in the previous example, Filters constrain the aliases, most notably in the case of the `SecInfo` instances, where we filter `secInfo1` and `secInfo2` for a specific value of `busDay` (today's date). However, we have only loosely constrained our `Security` instances – we merely have a Filter that prevents the same element of `Security` from being compared to itself (when `sec1 = sec2`). No other constraints are placed on the `Security` aliases.

Note that we are not assigning specific, single elements of `Security` to our aliases. Instead, we are instructing the Corticon Server to evaluate all *allowable* combinations (i.e., all those combinations that satisfy the 1<sup>st</sup> Filter) of `Security` elements in our collection in each of the aliases (`sec1` and `sec2`). For each allowable combination of `Security` elements, we will compare the `totalWeight` values from the associated `SecInfo` element for `busDay = today`, and increment the rank value for the first `SecInfo` element (`secinfo1`) by 1 if its `totalWeight` is greater than that of the second `SecInfo` object (`secinfo2`). The end result should be the relative performance ranking of each security that we want.

Figure 84: Rulesheet for Testing Alternate Security Ranking Model Rules

This figure shows a Ruletest constructed to test these ranking rules. In our data, we have added four `Security` elements and an associated `secInfo` element for each (note that each alias will represent ALL 4 `security` elements AND their associated `secInfo` elements). The current day at the time of the Ruletest is 2/9/2009, so each `Security.secInfo.busDay` attribute is given the value of 2/9/2009 (if we had included additional `secinfo` elements in each collection, they'd have earlier dates, and therefore would be filtered out by the Preconditions on each alias). We have initially set (or "initialized") each `Security.secInfo.rank` equal to 1, so that the lowest ranked security will still have a value of 1. The lowest ranked security will be the one that "loses" all comparisons with the other securities - in other words, its weight is less than the weights of all other securities. If a security's weight is less than all the other security weights, its rank will never be incremented by the rule, so its rank will remain 1. The values of `totalWeight` for the `SecInfo` objects are all different; therefore, we expect to see each security ranked between 1 and 4 with no identical `rank` values.

**Note:** If there were multiple `Security.secInfo` elements (multiple securities) with the same `totalWeight` value for the same day, then we would expect the final rank assigned to these objects to be the same as well. Further, if there were multiple `Security.secInfo` entities sharing the highest relative `totalWeight` value in a given Ruletest, then the highest rank value possible for that Ruletest would be lower than the number of securities being ranked, assuming we initialize all rank values at 1.

Figure 85: Rulesheet for Alternate Security Ranking Model Rules

The screenshot displays the 'AlternateRank.ers' rulesheet interface. The top section shows the 'Input' data, which is organized into four security entities (Security [1] through Security [4]). Each entity contains a 'ticker' field, a 'secInfo (SecInfo)' field, a 'busDay' field, a 'rank' field, and a 'totalWeight' field. The 'rank' field values are: Security [1] rank [4], Security [2] rank [1], Security [3] rank [3], and Security [4] rank [2]. The 'totalWeight' values are: Security [1] totalWeight [0.750000], Security [2] totalWeight [0.000000], Security [3] totalWeight [0.500000], and Security [4] totalWeight [0.250000].

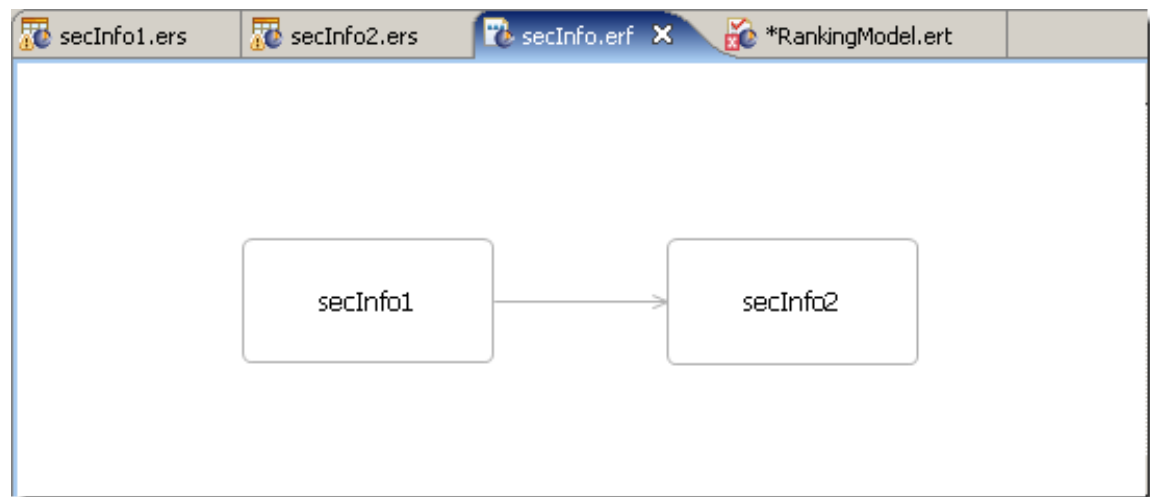

The bottom section shows the 'Rule Statements' and 'Rule Messages' tab. The 'Rule Messages' tab is active, displaying a table of rule firings. The table has three columns: 'Severity', 'Message', and 'Entity'. The messages are as follows:

Severity	Message	Entity
Info	If Security 1 [IBM] total weight > Security 2 [AMAT] total weight, then increment [IBM] rank by 1	Security[1]
Info	If Security 1 [AMAT] total weight > Security 2 [MSFT] total weight, then increment [AMAT] rank by 1	Security[4]
Info	If Security 1 [INTC] total weight > Security 2 [MSFT] total weight, then increment [INTC] rank by 1	Security[3]
Info	If Security 1 [IBM] total weight > Security 2 [INTC] total weight, then increment [IBM] rank by 1	Security[1]
Info	If Security 1 [INTC] total weight > Security 2 [AMAT] total weight, then increment [INTC] rank by 1	Security[3]
Info	If Security 1 [IBM] total weight > Security 2 [MSFT] total weight, then increment [IBM] rank by 1	Security[1]
Info	If Security 1 [AMAT] total weight <= Security 2 [INTC] total weight, then take no action	Security[4]
Info	If Security 1 [MSFT] total weight <= Security 2 [AMAT] total weight, then take no action	Security[2]
Info	If Security 1 [AMAT] total weight <= Security 2 [IBM] total weight, then take no action	Security[4]
Info	If Security 1 [INTC] total weight <= Security 2 [IBM] total weight, then take no action	Security[3]
Info	If Security 1 [MSFT] total weight <= Security 2 [IBM] total weight, then take no action	Security[2]
Info	If Security 1 [MSFT] total weight <= Security 2 [INTC] total weight, then take no action	Security[2]

In this figure, our Ruletest results are as expected. The security with the highest relative `totalWeight` value ends the Ruletest with the highest `rank` value after all rule evaluation is complete. The other securities are also assigned `rank` values based on the relative ranking of their `totalWeight` values. The individual rule firings that resulted in these outcomes are highlighted in the message section at the bottom of the results sheet.

It is interesting to note that nowhere in the rules is it stated how many security entities will be evaluated. This is another example of the ability of the declarative approach to produce the intended outcome without requiring explicit, procedural instructions.

**Figure 86: Ruleflow to test two Rulesheets in succession**

## Sorted aliases

You can create a special kind of alias in the Scope section of a Rulesheet. The technique uses the specialized Sequence operator `->next` against a Sorted Alias (a special cached Sequence) inside a filter expression. The Rulesheet is set into a Ruleflow that iterates to bind the alias in each successive invocation to the next element in the sequence.

The following example shows a Rulesheet based on the `Cargo` Vocabulary. We brought the `Cargo` entity and its `weight` attribute into the scope:

The operators `sortedBy` and `sortedByDesc` enable sorting ascending or descending order of the numeric or alphabetic values of the attribute in the set of data. Note that an attribute with a Boolean data type is not valid for this operation.

Dragging the `sortedBy` operator and dropping it (you cannot type it in) on the attribute `weight` places it in the scope yet shows an error:

The error message notes that a sorted alias node requires an alias name. When we enter an alias name, the scope is complete.

We add a filter expression to establish that, when we iterate through the list, each pass will present the next sequential item in the sorted set. We defined this by dragged `sortedBy` from the scope to filter line 1, and then appended the `->next` operator. We added a rule statement based on sorted load that echoes the weight so we can see the results in our tests.

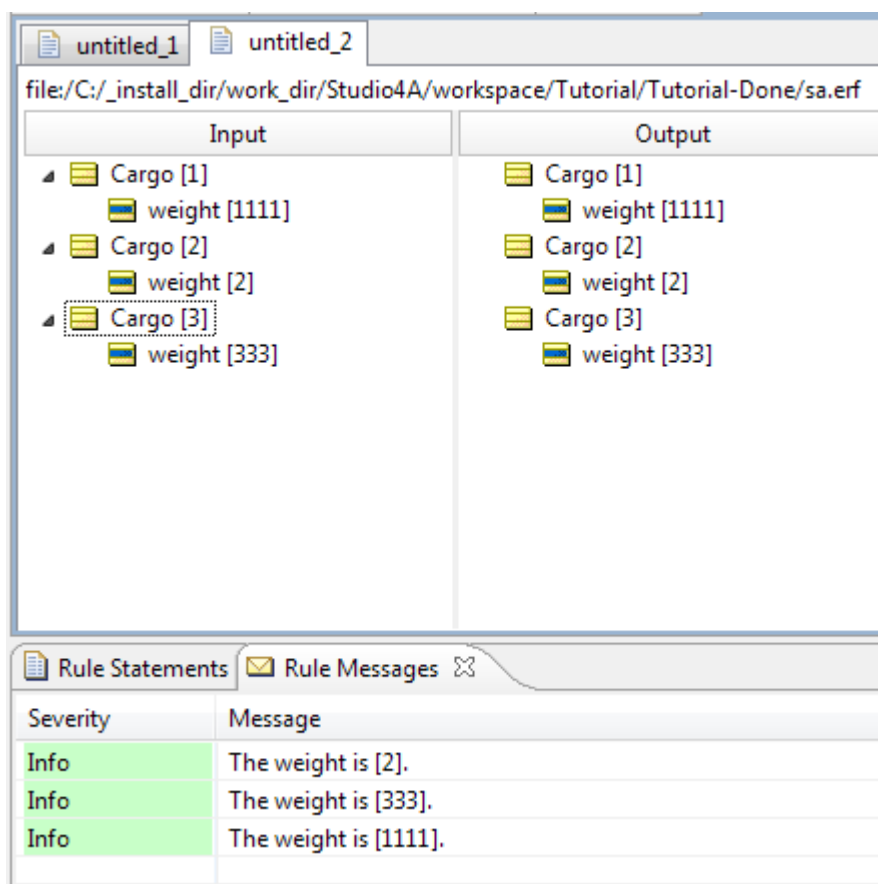

The screenshot displays the Corticon Rule Modeling interface with several tabs open: \*Cargo.ecore, \*SortedAliases.ers, \*SortedAliases.ert, \*sa.erf, and \*sa2.ers. The main workspace is divided into several panels:

- Scope:** A tree view showing the hierarchy: Cargo [load] > weight > sortedBy [sortedLoad] > Filters > sortedLoad->next > weight.
- Filters:** A list of filters, with 'sortedLoad->next' selected.
- Conditions:** A table with columns for conditions (a, b, c, d, e) and two columns for logical operators (0 and 1).
- Actions:** A table with columns for actions (A, B, C, D) and two columns for logical operators (0 and 1). The 'Post Message(s)' action is selected.
- Overrides:** A table for overrides.
- Rule Statements:** A table with columns for Ref, ID, Post, Alias, and Text. One statement is visible: Ref 1, ID, Post Info, Alias sortedLoad, Text 'The weight is [{sortedLoad.weight}].'
- Rule Messages:** A panel for rule messages.

We saved the Rulesheet and created a Ruleflow, adding in our Rulesheet. Then we dragged an **Iterative** operation to the Rulesheet in the Ruleflow and saved it.

We created a Ruletest with a few Cargo items, each with a weight that we expect to sequence numerically when we run the test. Each iteration posts a message, and that message (the corresponding Rule Statement) contains the embedded attribute load weight. Since each member of the load collection will “trigger” the nonconditional rule, and even though the elements will be processed in no particular order, we expect to see a set of resulting messages with load weight in order. Running the tests repeatedly outputs the weights in ascending order every time.

If we change the operator to `sortByDesc`, the results are shown in *descending* order by weight, as expected.

## Singletons

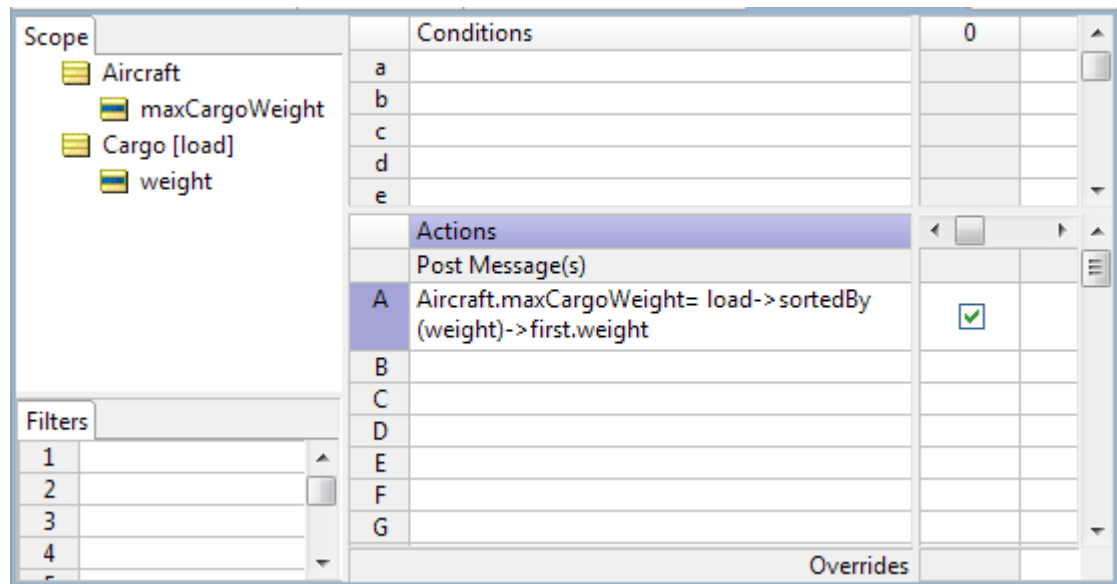

Singletons are collection operations that iterate over a set to extract one arithmetic value - the first, the last, the trend, the average, or the element at a specified position. We saw this behavior when the `sortedAlias` found the first and last element in an iterative list (as well as the elements in between) in the given order.

To examine this feature, we bring the `Aircraft` entity and its `maxCargoWeight` into the scope as well as `Cargo` (with the alias `load`) and its attribute `weight`. The nonconditional action we enter is, literally:

"Show me the maximum cargo weight by examining all the cargo in the load, sorting them by weight from small to large, and returning the smallest one first."

That is entered as:

```
Aircraft.maxCargoWeight=load->sortedBy(weight)->first.weight
```

When we extend the test we used for sorted aliases, we need to add an **Aircraft** with **maxCargoWeight** to show the result of the test. The result is as expected - the lightest item passed the test.

**Figure 87:**

The same result is output when we modify the rule to select last item when we sort the items by descending weight.

**Figure 88:**

Scope		Conditions		0	
└ Aircraft		a			
└ maxCargoWeight		b			
└ Cargo [load]		c			
└ weight					

Filters		Actions			
1			Post Message(s)		
2		A	Aircraft.maxCargoWeight=load->sortedByDesc(weight)->last.weight	<input checked="" type="checkbox"/>	
3		B			
		C			
		D			

Overrides

Now we reverse the test to select the first item when we sort the items by descending weight...

**Figure 89:**

Scope		Conditions		0	
└ Aircraft		a			
└ maxCargoWeight		b			
└ Cargo [load]		c			
└ weight		d			
		e			

Filters		Actions			
1			Post Message(s)		
2		A	Aircraft.maxCargoWeight=load->sortedByDesc(weight)->first.weight	<input checked="" type="checkbox"/>	
3		B			
4		C			
		D			
		E			
		F			
		G			

Overrides

...and the heaviest item is output.

**Figure 90:**

Input	Output	Expected
Cargo [1] weight [1111]	Cargo [1] weight [1111]	
Cargo [2] weight [2]	Cargo [2] weight [2]	
Cargo [3] weight [333]	Cargo [3] weight [333]	
Aircraft [1] aircraftType maxCargoVolume maxCargoWeight tailNumber	Aircraft [1] aircraftType maxCargoVolume <b>maxCargoWeight [1111.000000]</b> tailNumber	

**Note:** Singletons do not operate against an iterative Ruleflow as was required by Sorted Aliases. The tests apply directly to the Rulesheet.

## Special collection operators

There are two special collection operators available in Corticon Studio's Operator Vocabulary that allow us to evaluate collections for specific Conditions. These operators are based on two concepts from the predicate calculus: the *universal quantifier* and the *existential quantifier*. These operators return a result about the collection, rather than about any particular element within it. Although this is a simple idea, it is actually a very powerful capability – some decision logic cannot be expressed without these operators.

## Universal quantifier

The meaning of the universal quantifier is that a condition enclosed by parentheses is evaluated (i.e., its "truth value" is determined) *for all* instances of an entity or collection. This is implemented as the `->forAll` operator in the Operator Vocabulary. We will demonstrate this operator with an example created using the Vocabulary from our security ranking model. Note that these operators act on collections, so all the examples shown will declare aliases in the **Scope** section.

**Figure 91: Rulesheet with Universal Quantifier ("for all") Condition**

The screenshot shows the Rule Modeling Guide interface. On the left is a tree view of the Operator Vocabulary, with 'forAll (expression)' selected under 'Collection'. The main area is titled 'UniversalQuantifier.ers' and contains the following sections:

- Scope:** A tree showing 'Security [secty]' containing 'rating' and 'secInfo (SecInfo) [secinfo]'.
- Conditions:** A table with 3 columns (0, 1, 2) and 5 rows (a-e). Row 'a' contains the condition: `secinfo -> forAll(secinfo.rank >=3)`.
- Filters:** A list of 5 filters, all empty.
- Actions:** A table with 3 columns (0, 1, 2) and 3 rows (A-C). Row 'A' contains the action: `secty.rating`.
- Overrides:** A table with 3 columns (0, 1, 2) and 1 row, all empty.
- Rule Statements:** A table with 5 columns (Ref, ID, Post, Alias, Text) and 2 rows. Row 1: Ref 1, ID Info, Post secty, Text 'A security for which all rank values are greater than or equal to 3 should be assigned a rating of high'. Row 2: Ref 2, ID Info, Post secty, Text 'A security for which not all rank values are greater than or equal to 3 should be assigned a rating of low'.

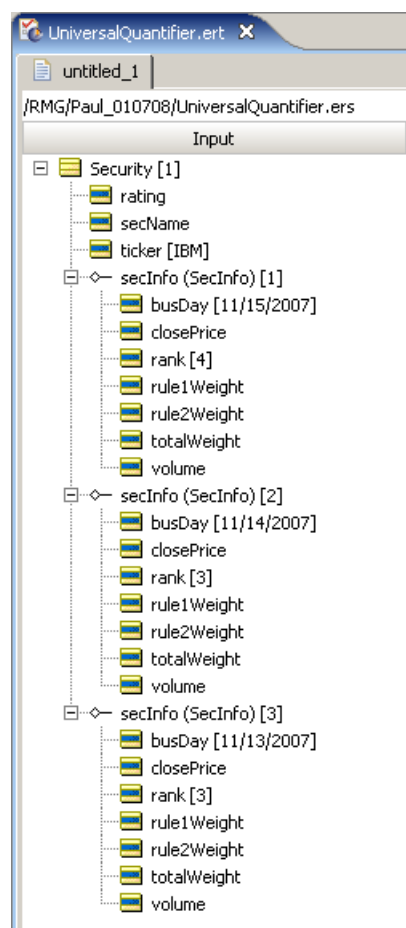

In this figure, we see the Condition

```
secinfo ->forAll(secinfo.rank >= 3)
```

The exact meaning of this Condition is that for the collection of `SecInfo` elements associated with a `Security` (represented and abbreviated by the alias `secInfo`), evaluate if the expression in parentheses (`secinfo.rank >= 3`) is true **for all** elements. The result of this Condition is Boolean because it can only return a value of true or false. Depending on the outcome of the evaluation, a value of either `High` or `Low` will be assigned to the `rating` attribute of our `Security` entity and the corresponding Rule Statement will be posted as a message to the user.

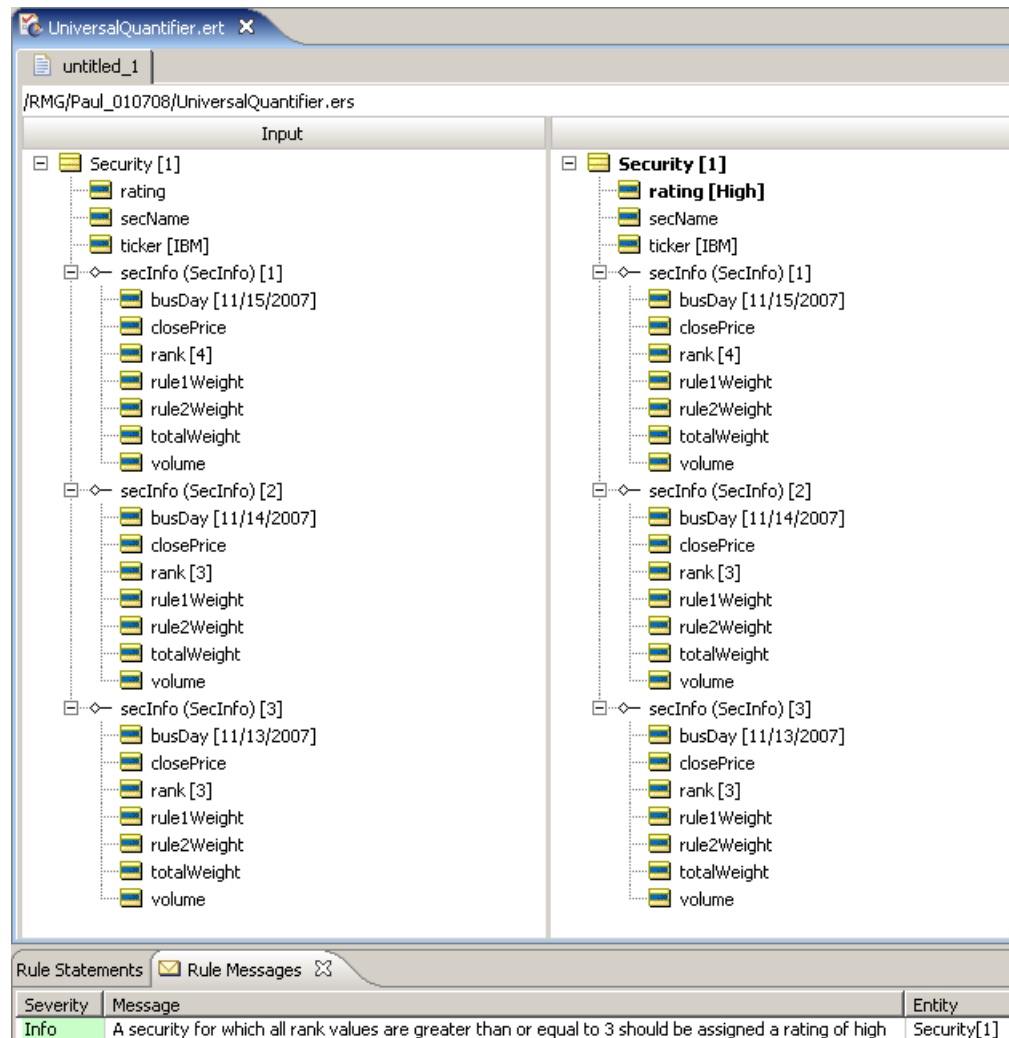

The following figure shows a Ruletest constructed to test our "for all" Condition rules.

**Figure 92: Ruletest for Testing "for all" Condition Rules**

In this Ruletest, we are evaluating a collection of three `SecInfo` elements associated with a `Security` entity. Since the `rank` value assigned in each `SecInfo` object is at least 3, we should expect that our "for all" Condition will evaluate to `true` and a rating value of `High` will be assigned to our `Security` object when the Ruletest is run through Corticon Server. This outcome is confirmed in the Ruletest results, as shown:

**Figure 93: Ruletest for "for all" Condition Rules**

## Existential quantifier

The other special operator available is the existential quantifier. The meaning of the existential quantifier is that *there exists at least one* element of a collection for which a given condition evaluates to true. This logic is implemented in the Rulesheet > using the `->exists` operator from our Operator Vocabulary.

As in our last example, we can construct a Rulesheet to determine the `rating` value for a `Security` entity by evaluating a collection of associated `SecInfo` elements with the existential quantifier. In this new example, we will use `volume` rather than `rank` to determine the `rating` value for the security. The Rulesheet for this example is shown in the following figure:

**Figure 94: Rulesheet with Existential Quantifier ("exists") Condition**

The screenshot shows the `ExistentialQuantifier.rules` editor. The left pane shows the rule structure with the `exists` operator selected under the `Collection` operators. The main editor displays the following configuration:

Scope	Conditions	0	1	2
a	secinfo ->exists(volume > 1000)	-	T	F
b				
c				
d				
e				

Filters	Actions	0	1	2
1				
2				
3				
4				
5				

Ref	ID	Post	Alias	Text
1		Info	secity	A security for which there exists a volume greater than 1000 must be classified 'High Volume'
2		Info	secity	A security for which there does not exist a volume greater than 1000 must be classified 'Normal Volume'

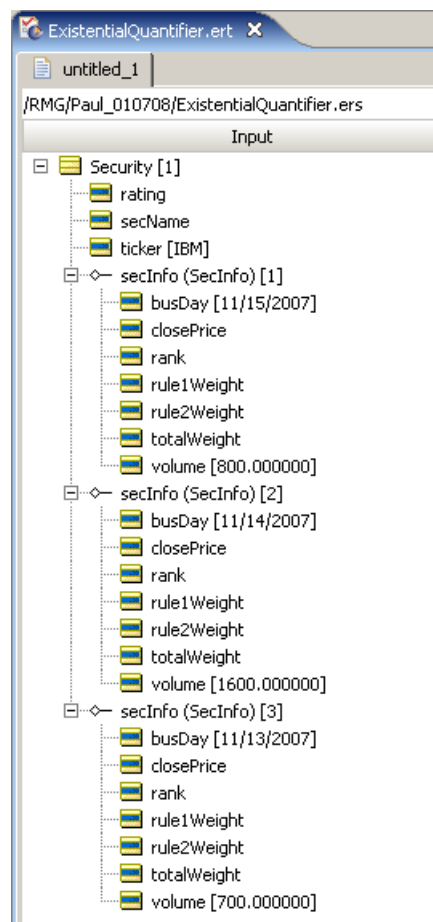

In this Rulesheet, we see the Condition

```
secinfo ->exists(secinfo.volume >1000)
```

Notice again the *required* use of an alias to represent the collection being examined. The exact meaning of the Condition in this example is that for the collection of `SecInfo` elements associated with a `Security` (again represented by the `secinfo` alias), determine if the expression in parentheses (`secinfo.volume > 1000`) holds **true** for *at least one* `Secinfo` element. Depending on the outcome of the `exists` evaluation, a value of either `High Volume` or `Normal Volume` will be assigned to the `rating` attribute of our `Security` object and the corresponding Rule Statement will be posted as a message to the user.

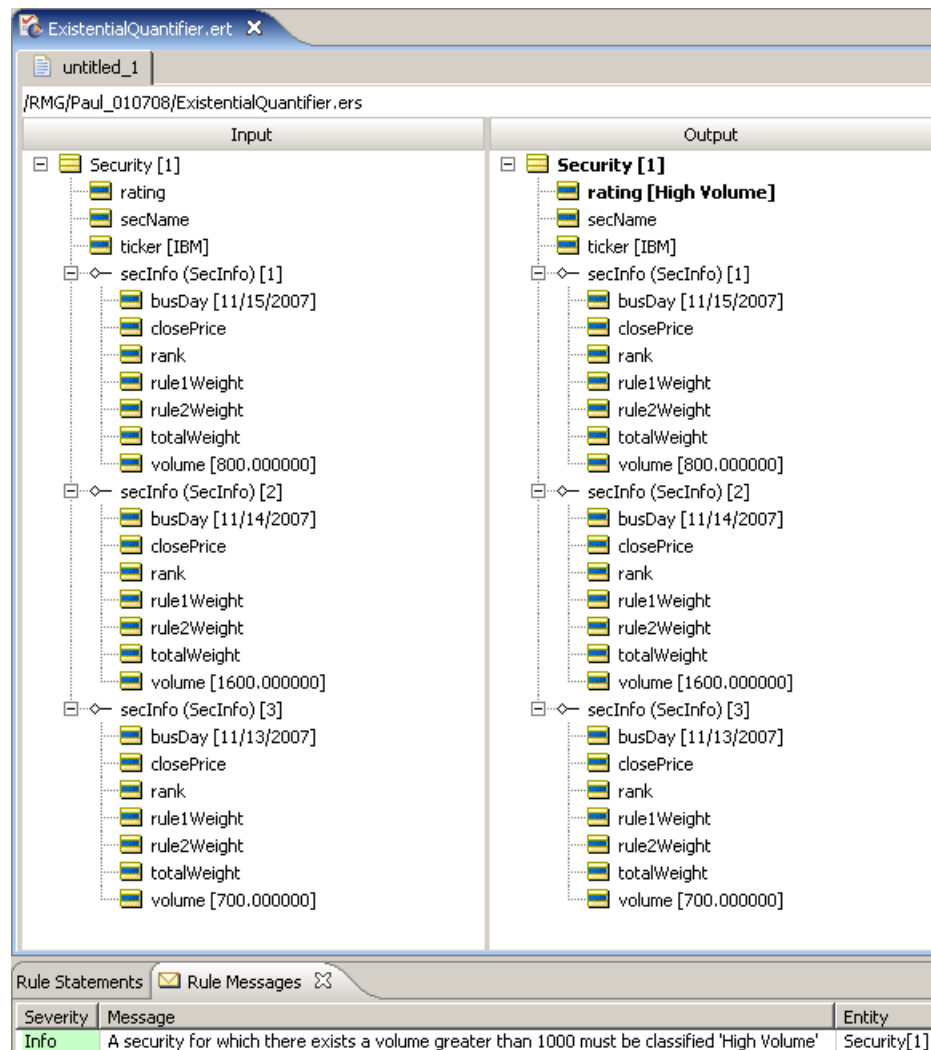

The following figure shows a Ruletest constructed to test our `exists` Condition rules.

**Figure 95: Ruletest for Testing `exists` Condition Rules**

Once again, we evaluate a collection of 3 `SecInfo` elements associated with a single `Security` entity. Since the `volume` attribute value assigned in at least one of the `SecInfo` objects (`secInfo[2]`) is greater than 1000, we should expect that our `exists` Condition will evaluate to **true** and a `rating` value of `High Volume` will be assigned to our `Security` object when the Ruletest is run through Corticon Server. This outcome is confirmed in the Ruletest shown in the following figure.

**Figure 96: Ruletest for `exists` Condition Rules**

## Another example using the existential quantifier

Collection operators are powerful parts of the Corticon Rule Language – in some cases they may be the only way to implement a particular business rule. For this reason, we provide another example.

**Business problem:** An auto insurance company has a business process for handling auto claims. Part of this process involves determining a claim's validity based on the information submitted on the claim form. For a claim to be classified as valid, both the driver and vehicle listed on the claim must be covered by the policy referenced by the claim. Claims that are classified as invalid will be rejected, and will not be processed for payment.

From this short description, we extract our primary business rule statement:

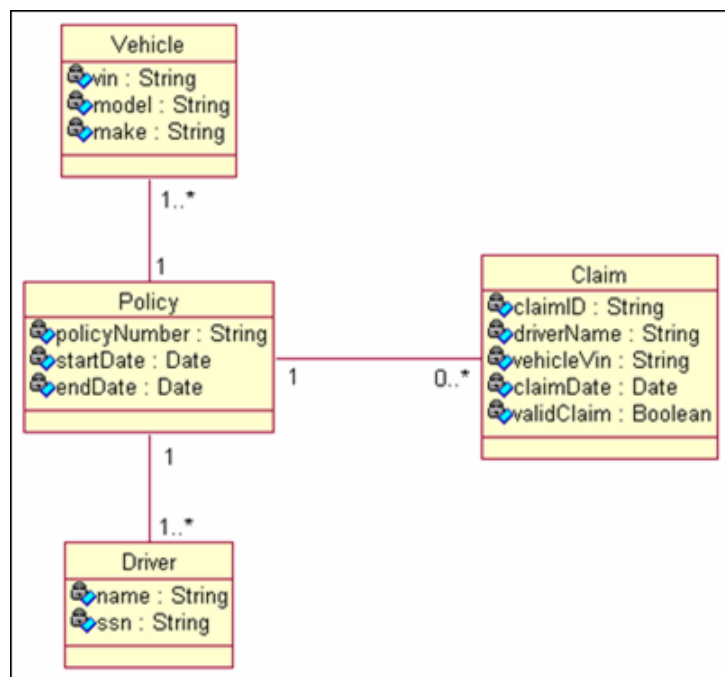

1. A claim is valid if the driver and vehicle involved in a claim are both listed on the policy against which the claim is submitted.

In order to implement our business rule, we propose the **UML Class Diagram** shown below. Note the following aspects of the diagram:

- A Policy may cover one or more Drivers
- A Policy may cover one or more Vehicles
- A Policy may have zero or more Claims submitted against it.
- The Claim entity has been denormalized to include `driverName` and `vehicleVin`.

**Note:** Alternatively, the Claim entity could have referenced `Driver.name` and `Vehicle.vin` (by adding associations between Claim and both Driver and Vehicle), respectively, but the denormalized structure is probably more representative of a real-world scenario.

**Figure 97: UML Class Diagram**

This model imports into Corticon Studio as the Vocabulary shown in [Figure 98](#) on page 115

**Figure 98: Vocabulary**

Model the following rules in Corticon Studio as shown in [Figure 99](#) on page 115

1. For a claim to be valid, the driver's name and vehicle ID listed on the claim must also be listed on the claim's policy.
2. If either the driver's name or vehicle ID on the claim is not listed on the policy, then the claim is not valid.

**Figure 99: Rules Modeled in Corticon Studio**

Conditions	0	1	2	3
a aClaim.driverName = aClaim.policy.driver.name	-	T	F	-
b aClaim.vehicleVin = aClaim.policy.vehicle.vin	-	T	-	F
c				
d				

Actions	0	1	2	3
Post Message(s)				
A aClaim.validClaim		T	F	F
B				

Ref	ID	Post	Alias	Text
1		Info	aClaim	A claim is valid if its driver [{aClaim.driverName}] AND Vehicle match the policy against it was submitted [{aClaim.policy.driver.name}] and [{aClaim.policy.vehicle.vin}]
2		Warning	aClaim	A claim is not valid if its driver [{aClaim.driverName}] is not on the policy against which it was submitted [{aClaim.policy.driver.name}]
3		Warning	aClaim	A claim is not valid if its vehicle [{aClaim.vehicleVin}] is not on the policy against which it was submitted [{aClaim.policy.vehicle.vin}]

This appears very straightforward. But a problem arises when there are multiple drivers and/or vehicles listed on the policy—in other words, when the policy contains a collection of drivers and/or vehicles. Our Vocabulary permits this scenario because of the cardinalities we assigned to the various associations. We demonstrate this problem with the Ruletest in [Figure 100](#) on page 116

**Figure 100: Ruletest**

Notice in [Figure 101](#) on page 117 that there are 3 drivers and 3 vehicles listed on (associated with) a single policy. When we run this Ruletest, we see the results:

**Figure 101: Ruletest**

The screenshot shows the Corticon Studio Ruletest interface. The top pane displays the rule model for 'Claim'. The 'Input' tree shows a claim with driverName [Joe], validClaim, and vehicleVin [123-ABC]. The 'Output' tree shows the same claim but with validClaim [false]. Below the trees is a table of Rule Messages showing 5 warnings about claim validity.

Severity	Message	Entity
Info	A claim is valid if its driver [Joe] AND Vehicle match the policy against it was submitted [Joe] and [123-ABC]	Claim[1]
Warning	A claim is not valid if its driver [Joe] is not on the policy against which it was submitted [Sue]	Claim[1]
Warning	A claim is not valid if its driver [Joe] is not on the policy against which it was submitted [Mary]	Claim[1]
Warning	A claim is not valid if its vehicle [123-ABC] is not on the policy against which it was submitted [987-XYZ]	Claim[1]
Warning	A claim is not valid if its vehicle [123-ABC] is not on the policy against which it was submitted [456-JKL]	Claim[1]

As we see from the Ruletest results, the way Corticon Studio evaluates rules involving comparisons of multiple collections means that the `validClaim` attribute may have inconsistent assignments – sometimes `true`, sometimes `false` (as in this Ruletest). It can be seen from the table below that, given the Ruletest data, 4 of 5 possible combinations evaluate to `false`, while only one evaluates to `true`. This conflict arises because of the nature of the data evaluated, not the rule logic, so Studio's Conflict Check feature does not detect it.

Claim. driverName	Claim.policy. driver.name	Claim. vehicleVin	Claim.policy. vehicle.vin	Rule 1 fires	Rule 2 fires	Rule 3 fires	validClaim
Joe	Joe	123-ABC	123-ABC	X			True
Joe	Sue				X		False
Joe	Mary				X		False
		123-ABC	987-XYZ			X	False
		123-ABC	456-JKL			X	False

Let's use the existential quantifier to rewrite these rules:

**Figure 102: Rules Rewritten Using Existential Quantifier.**

The screenshot shows the ExistentialAutoClaim.ers rule editor. The left pane displays a tree view of the rule structure: Claim [c] contains driverName, validClaim, and vehicleVin. The policy attribute contains two collections: driver [cpd] and vehicle [cpv]. The main pane is divided into Conditions, Actions, and Overrides sections. The Conditions section contains two rules: 'a' (cpd -> exists(name = c.driverName)) and 'b' (cpv -> exists(vin = c.vehicleVin)). The Actions section contains a 'Post Message(s)' table with columns A, B, C, D, E, and F. The Overrides section is empty. The bottom pane shows Rule Statements and Rule Messages. The Rule Messages table has columns Ref, ID, Post, Alias, and Text.

Ref	ID	Post	Alias	Text
A1		Warning	c	A claim is not valid if its driver [{c.driverName}] is not on the policy against which it is submitted
A2		Warning	c	A claim is not valid if its vehicle [{c.vehicleVin}] is not on the policy against which it is submitted
A3		Info	c	A claim is valid if its driver [{c.driverName}] AND vehicle [{c.vehicleVin}] match those on the policy against which it is submitted

This logic tests for the existence of matching drivers and vehicles within the two collections. If matches exist within both, then the `validClaim` attribute evaluates to true, otherwise `validClaim` is false.

Let's use the same Ruletest data as before to test these new rules. The results are shown below:

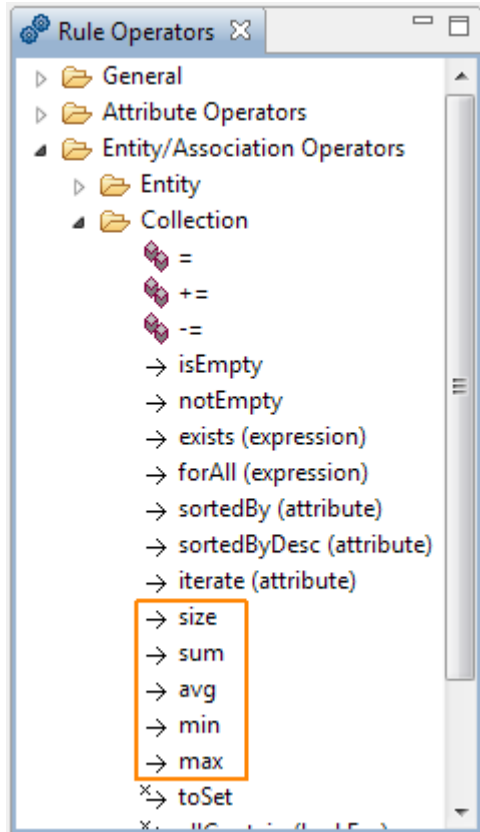

The screenshot shows the autoClaim.ert rule test results. The left pane displays the 'Input' tree view, and the right pane displays the 'Output' tree view. The 'Input' tree shows a Claim [1] with driverName [Joe], validClaim, and vehicleVin [123-ABC]. The policy (Policy) [1] contains three drivers (Driver) [1], [2], and [3], each with a name (Mary, Sue, Joe) and three vehicles (Vehicle) [1], [2], and [3], each with a vin (456-JKL, 987-XYZ, 123-ABC). The 'Output' tree shows the same structure, but with validClaim [true]. The bottom pane shows Rule Statements and Rule Messages. The Rule Messages table has columns Severity, Message, and Entity.

Severity	Message	Entity
Info	A claim is valid if its driver [Joe] AND vehicle [123-ABC] match those on the policy against which it is submitted	Claim[1]

Notice that only one rule has fired, and that `validClaim` has been assigned the value of true. This implementation achieves the intended result.

## Aggregations that optimize database access

A subset of collection operators are known as *aggregation operators* because they evaluate a collection to compute one value. These aggregation operators are as highlighted:

When these aggregations are applied through the Enterprise Data Connector in a Rulesheet set to **Extend to Database**, the performance impact against large tables can be minimized by performing non-conditional actions that force the calculations onto the database. For an example of this, see [Optimizing Aggregations that Extend to Database](#) on page 205

## Test yourself - questions – collections

**Note:** Try this test, and then go to **Answers:** [Collections](#) on page 284 to correct yourself.

1. Children of a Parent entity are also known as \_\_\_\_\_ of a collection.
2. True or False. All collections must have a parent entity
3. True or False. Root-level entities may form a collection
4. True or False. A collection operator must operate on a collection alias.
5. List three Collection operators and describe what they do.
6. Which reference contains usage details and examples for every collection operator?

7. Write a Rule Statement that is equivalent to the syntax `Order.total = items.price->sum`
8. In the syntax in question 7, which term is the collection alias?
9. If `items` is an alias representing the `LineItem` entities associated with an `Order` entity, then what would you expect the cardinality of this association to be?
10. Is `Order.lineItem.price->sum` an acceptable replacement for the syntax in Question 7? Why or why not?
11. If you are a Vocabulary designer and want to prevent rule authors from building rules with `LineItem.order` terms, what can you do to prevent it?
12. When collection operators are NOT used in a Rulesheet, aliases are (circle all that apply)

Optional	Mandatory	Colorful	Convenient
----------	-----------	----------	------------

13. If a Nonconditional rule states `LineItem.price = 100`, and my Input Testsheet contains 7 `LineItem` entities, then a collection of data is processed by this rule. Is a collection alias required? Why or why not?
14. Which collection operator is known as the Universal Quantifier?
15. Which collection operator is known as the Existential Quantifier?

For questions 16-18, refer to the following Vocabulary

16. Write expressions for each of the following phrases:

- If an actor has had more than 3 roles...
- If a movie has not been released on DVD...
- If a movie has at least one DVD with deleted scenes...
- If a movie won at least one Golden Globe
- If the movie had more than 15 actors...
- If there's at least 100 copies available of a movie...
- If there's less than 2 copies available of a movie...
- If the DVD can be obtained from more than 1 supplier...

17. Which entities could be grandchildren of Movie?

18. Which entities could be children of Role?

19. Describe the difference between `->forAll` and `->exists` operators.

20. Describe the difference between `->notEmpty` and `->isEmpty` operators.
21. Why are aliases required to represent collections?

---

## Rules containing calculations & equations

---

Rules that contain equations and calculations are really no different than any other type of rule. Calculation-containing rules may be expressed in any of the sections of the Rulesheet.

For details, see the following topics:

- [Terminology](#)
- [Operator precedence](#)
- [Datatype compatibility and casting](#)
- [Supported uses of calculation expressions](#)

### Terminology

First we will introduce some terminology that will be used throughout this chapter. In the simple expression  $A = B$ , we define  $A$  to be the *Left-hand Side* (LHS) of the expression, and  $B$  to be the *Right-hand Side* (RHS). The equals sign is an *Operator*, and is included in the Operator Vocabulary in Corticon Studio. But even such a simple expression has its complications. For example, does this expression compare the value of  $A$  to  $B$  in order to take some action, or does it instead assign the value of  $B$  to  $A$ ? In other words, is the equals operator performing a *comparison* or an *assignment*? This is a common problem in programming languages, where a common solution is to use two different operators to distinguish between the two meanings -- the symbol `==` might signify a comparison operation, whereas `:=` might signify an assignment.

In Corticon Studio, special syntax is unnecessary because the Rulesheet itself helps to clarify the logical intent of the rules. For example, typing `A=B` into a Rulesheet's Condition row (and pressing **Enter**) automatically causes the Values set `{T, F}` to appear in the rule column cell drop-down lists. This indicates that the rule modeler has written a comparison expression, and Studio expects a value of `true` or `false` to result from the comparison. `A=B`, in other words, is treated as a test – is `A` equal to `B` or isn't it?

On the other hand, when `A=B` is entered into an Action or Nonconditional row (Actions rows in Column 0), it becomes an assignment. In an assignment, the RHS of the equation is evaluated and its value is assigned to the LHS of the equation. In this case, the value of `B` is simply assigned to `A`. As with other Actions, we have the ability to activate or deactivate this Action for any column in the decision table (numbered columns in the Rulesheet) simply by "checking the box" that automatically appears when the Action's cell is clicked.

In the *Rule Language Guide*, the equals operator (`=`) is described separately in both its assignment and comparison contexts.

## Operator precedence

Operator precedence, or the order in which Corticon Studio evaluates multiple operators in an equation, is defined by the table in "Arithmetic operator precedence" of the *Rule Language Guide*. This table specifies for example, that `2*3+4` evaluates to 10 and not 14 because the multiplication operator `*` has a higher precedence than the addition operator `+`. It is a good practice, however, to include clarifying parentheses even when Corticon Studio does not require it. This equation would be better expressed as `(2*3)+4`. Note the addition of parentheses here does not change the result. When expressed as `2*(3+4)`, however, the result becomes 14.

## Datatype compatibility and casting

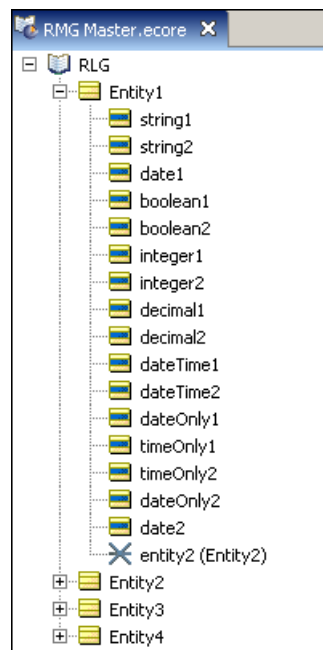

An important prerequisite of any comparison or assignment operation is data type compatibility. In other words, the data type of the equation's LHS (the data type of `A`) must be compatible with whatever data type results from the evaluation of the equation's RHS (the data type of `B`). For example, if both attributes `A` and `B` are Decimal types, then there will be no problem assigning the Decimal value of attribute `B` to attribute `A`.

Similarly, a comparison between the LHS and RHS makes no real sense unless both refer to the same kinds of data. How does one compare `orange` (a String) to `July 4, 2014` (a Date)? Or `false` (a Boolean) to `247.82` (a Decimal)?

In general, the data type of the LHS must match the data type of the RHS before a comparison or assignment can be made. (The exception to this rule is the comparison or assignment of an Integer to a Decimal. A Decimal can safely contain the value of an Integer without using any special casting operations.) Expressions that result in inappropriate data type comparison or assignment should turn red in Studio.

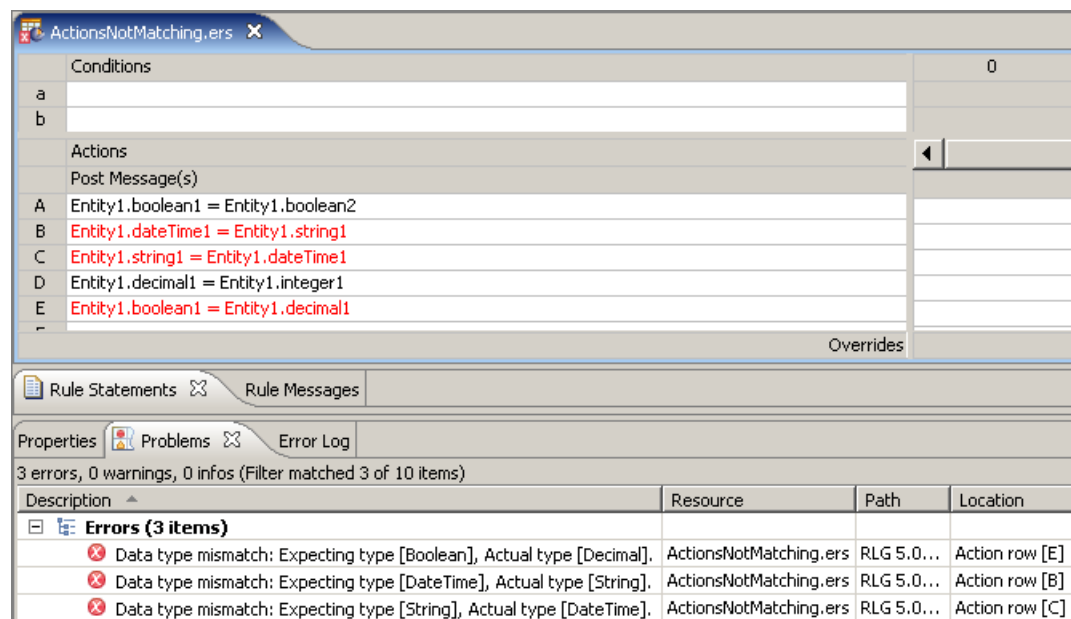

In the examples that follow, we will use the generic Vocabulary from the *Rule Language Guide*, since the generic attribute names indicate their data types:

**Figure 103: Generic Vocabulary used in the Rule Language Guide**

The following figure shows a set of Action rows that illustrate the importance of data type compatibility in assignment expressions:

**Figure 104: Datatype Mismatches in Assignment Expressions**

Let's examine each of the Action rows to understand why each is valid or invalid.

**A** – this expression is valid because the data types of the LHS and RHS sides of the equation are compatible (they're both Boolean).

**B** – this expression is invalid and turns red because the data types of the LHS and RHS sides of the equation are incompatible (the LHS resolves to a DateTime and the RHS resolves to a String).

**C** – this expression is invalid and turns red because the data types of the LHS and RHS sides of the equation are incompatible (the LHS resolves to a String and the RHS resolves to a DateTime).

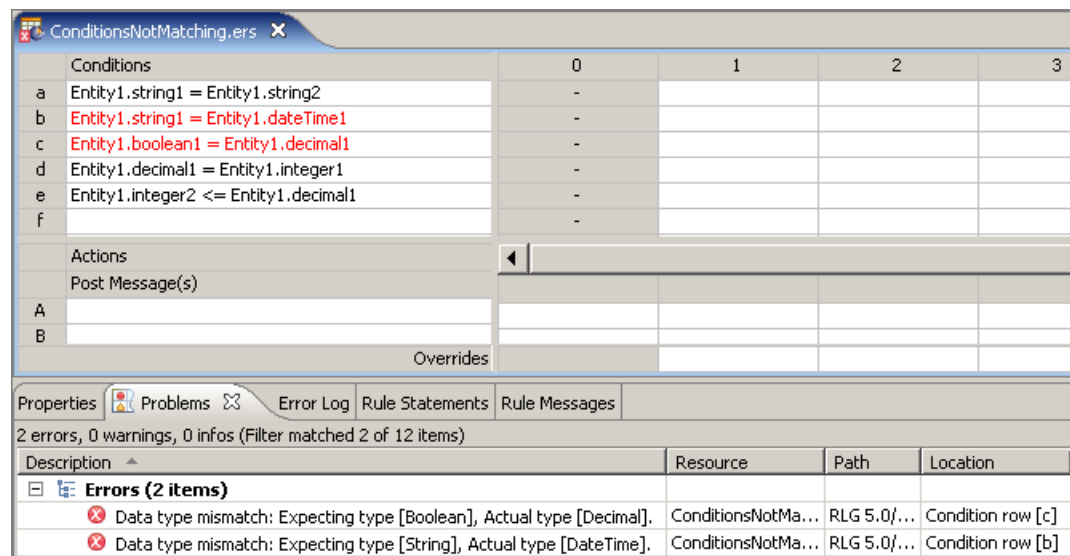

**D** – this expression is valid because the data types of the LHS and RHS sides of the equation are compatible *even though they are different!* This is an example of the one exception to our general rule regarding data type compatibility: Decimals can safely hold Integer values.

**E** – this expression is invalid and turns red because the data types of the LHS and RHS sides of the equation are incompatible (the LHS resolves to a Boolean and the RHS resolves to a Decimal). Here, the tool tip provides essentially the same information.

Note that the **Problems** window contains explanations for the red text shown in the *Rulesheet*.

The following figure shows a set of Conditional expressions that illustrate the importance of data type compatibility in comparisons:

**Figure 105: Datatype Mismatches in Comparison Expressions**

Let's examine each of these Conditional expressions to understand why each is valid or invalid:

**a** – This comparison expression is valid because the data types of the LHS and RHS sides of the equation are compatible (they're both Strings). Note that Corticon Studio confirms the validity of the expression by recognizing it as a comparison and automatically entering the Values set { T, F } in the Values column.

**b** – This comparison expression is invalid because the data types of the LHS and RHS sides of the equation are incompatible (the LHS resolves to a String and the RHS resolves to a DateTime). Note that, in addition to the red text, Corticon Studio emphasizes the problem by not entering the Values set { T, F } in the Values column.

**c** – This comparison expression is invalid because the data types of the LHS and RHS sides of the equation are incompatible (the LHS resolves to a Boolean and the RHS resolves to a Decimal).

**d** – This comparison expression is valid because the data types of the LHS and RHS sides of the equation are compatible. This is another example of the one exception to our general rule regarding data type compatibility: Decimals may be safely compared to Integer values.

**e** – This comparison expression is valid because the data types of the LHS and RHS sides of the equation are compatible. Like example 4, this illustrates the one exception to our general rule regarding data type compatibility: Decimals may be safely compared to Integer values. Unlike an assignment, however, whether the Integer and Decimal types occupy the LHS or RHS of a comparison is unimportant.

## Datatype of an expression

It is important to emphasize that the idea of a data type applies not only to specific attributes in the Vocabulary, but to entire expressions. Our examples above have been simple, and the data types of the LHS or the RHS of an equation simply correspond to the data types of those single attributes. But the data type to which an expression resolves may be a good deal more complicated.

**Figure 106: Examples of Expression Datatypes**

Again, we will examine each assignment to understand what is happening:

**A** – The RHS of this equation resolves to an Integer data type because the `.dayOfWeek` operator "extracts" the day of the week from a DateTime value (in this case, the value held by attribute `dateTime1`) and returns it as an Integer between 1 and 7. Since the LHS also has an Integer data type, the assignment operation is valid.

**B** – The RHS of this equation resolves to an Integer because the `.size` operator counts the number of characters in a String (in this case the String held by attribute `string1`) and returns this value as an Integer. Since the LHS also has an Integer data type, the assignment operation is valid.

**C** – The RHS of this equation resolves to a Boolean because the `->isEmpty` collection operator examines a collection (in this case the collection of `Entity2` children associated with parent `Entity1`, represented by collection alias `e2`) and returns `true` if the collection is empty (has no elements) or `false` if it isn't. Since the LHS also has a Boolean data type, the assignment operation is valid.

**D** – The RHS of this equation resolves to a Boolean because the `->exists` collection operator examines a collection (in this case, `e2` again) and returns `true` if the expression in parentheses is satisfied at least once, and `false` if it isn't. Since the LHS also has a Boolean data type, the assignment operation is valid.

**E** – the RHS of this equation resolves to an Integer because the `->sum` collection operator adds up the values of all occurrences of an attribute (in this case, `integer2`) in a collection (in this case, `e2` again). Since the LHS has a Decimal data type, the assignment operation is valid. This is the lone case where type casting occurs automatically.

---

**Note:** The `.dayOfWeek` operator and others used in these examples are described fully in the *Rule Language Guide*

---

## Defeating the parser

The part of Corticon Studio that checks for data type mismatches (along with all other syntactical problems) is the Parser. The Parser exists to ensure that whatever is expressed in a Rulesheet can be correctly translated and compiled into code executable by Corticon Studio's Ruletest as well as by the Corticon Server. Because this is a critical function, much effort has been put into the Parser's accuracy and efficiency. But rule modelers should understand that the Parser is not perfect, and can't anticipate all possible combinations of the rule language. It is still possible to "slip one past" the Parser. Here is an example:

**Figure 107: LHS and RHS Resolve to Integers**

In the figure above, we see an assignment expression where both LHS and RHS return Integers under all circumstances. But making a minor change to the RHS throws this result into confusion:

**Figure 108: Will the RHS Still Resolve to an Integer?**

The minor change of adding a division step to the RHS expression has a major effect on the data type of the RHS. Prior to modification, the RHS always returns an Integer, but an *odd* Integer! When we divide an odd Integer by 2, a Decimal always results. The Parser is smart, but not smart enough to catch this problem.

When the rule is executed, what happens? How does the Corticon Server react when the rule instructs it to force a Decimal value into an attribute of type Integer? The server responds by truncating the Decimal value. For example if `integer2` has the value of 2, then the RHS returns the Decimal value of 2.5. This value is truncated to 2 and then assigned to `integer1` in the LHS.

When we focus on this rule here, alone and isolated, it's relatively easy to see the problem. But in a complex Rulesheet, it may be difficult to uncover this sort of problem. Your only clue to its existence may be numerical test results that do not match the expected values. To be safe, it's usually a good idea to ensure the LHS of numeric calculations has a Decimal data type so no data is inadvertently lost through truncation.

## Manipulating datatypes with casting operators

A special set of operators is provided in the Corticon Studio's Operator Vocabulary that allows the rule modeler to control the data types of attributes and expressions. These casting operators are described below:

Table 2: Table: Special Casting Operators

Casting Operator	Applies to data of type...	Produces data of type...
.toInteger	Decimal, String	Integer
.toDecimal	Integer, String	Decimal
.toString	Integer, Decimal, DateTime, Date, Time	String
.toDateTime	String, Date, Time	DateTime
.toDate	DateTime	Date
.toTime	DateTime	Time

Returning to [Datatype Mismatches in Comparison Expressions](#), we use these casting operators to correct some of the previous problems:

Figure 109: Using Casting Operators

Casting operators have been used in Nonconditional rules N.2 and N.3 to make the data types of the LHS and RHS match. Notice however, that no casting operator exists to cast a Decimal into a Boolean data type.

## Supported uses of calculation expressions

To make our examples more interesting and allow for a bit more complexity in our rules, we have extended the basic Tutorial Vocabulary (`Cargo.ecore`) to include a few more attributes. The extended Vocabulary is shown below:

**Figure 110: Basic Tutorial Vocabulary Extended**

The new attributes are described in the table below:

**Table 3: Table: Table of New Attributes Added to the Basic Tutorial Vocabulary**

Attribute	Data type	Description
<code>Aircraft.emptyWeight</code>	Decimal	The weight of an Aircraft with no fuel or cargo onboard.
<code>Aircraft.grossWeight</code>	Decimal	The maximum amount of weight an Aircraft can safely lift, equal to the sum of cargo and fuel weights.
<code>Aircraft.maxfuel</code>	Decimal	The maximum amount of fuel an Aircraft can carry.
<code>Cargo.footprint</code>	Decimal	The floor space, measured in square feet, taken up by this Cargo.
<code>FlightPlan.approved</code>	Boolean	Indicates whether the FlightPlan has been approved or "cleared" for operation.
<code>FlightPlan.planWeight</code>	Decimal	The total amount of all Aircraft and Cargo weights for this FlightPlan.
<code>FlightPlan.flightRange</code>	Decimal	The distance the Aircraft is expected to fly.
<code>FlightPlan.fuel</code>	Decimal	The amount of fuel actually loaded on the Aircraft assigned to this FlightPlan.

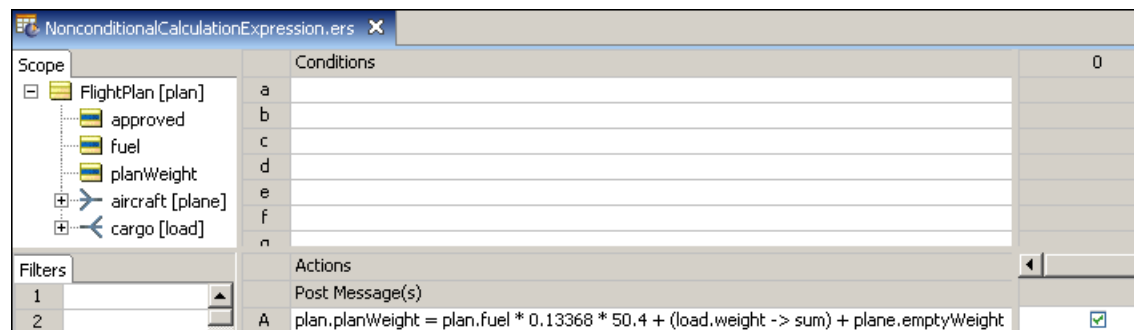

## Calculation as a comparison in a precondition

**Figure 111: A Calculation in a Preconditional Expression**

In this figure, a numeric calculation is used as a comparison in the Filters section of the Rulesheet. The LHS of the expression essentially calculates the average pressure exerted by the total cargo load on the floor of the aircraft (sum of the cargo weights divided by the sum of the cargo containers' footprints). This result is compared to the RHS, which is simply the literal value 5. We might expect to see this type of calculation in a set of rules that deals with special cargos where a lot of weight is concentrated in a small area. This might, for example, require the use of special aircraft with sturdy, reinforced cargo bay floors. Such a Filter expression might be the first step in handling cargos that satisfy this special criterion.

## Calculation as an assignment in a noncondition

Figure 112: A Calculation in a Nonconditional Expression

The example shown in this figure uses a calculation in the RHS of the assignment to derive the total weight carried by an Aircraft on the FlightPlan, where the total weight equals the weight of the fuel plus the weight of all Cargos onboard plus the empty weight of the Aircraft itself. The portion

```
plan.fuel * 0.13368 * 50.4
```

converts a fuel load measured in gallons into a weight measured in pounds – conversion factors of 0.13368 cubic feet per gallon and 50.4 pounds per cubic foot of jet fuel have been used here. This portion is then added to:

```
load.weight -> sum
```

which, of course, is equal to the sum of all Cargo weights loaded onto the Aircraft associated with this FlightPlan. The final sum of the fuel, cargo, and Aircraft weights is assigned to the FlightPlan's `planWeight`. Note the parentheses used here are not required – the calculation will produce the same result without them – they have been added for improved clarity.

## Calculation as a comparison in a condition

Once `planWeight` has been derived by the Nonconditional calculation in the figure below, it may be used immediately elsewhere in this or subsequent Rulesheets.

**Note:** "Subsequent Rulesheets" means Rulesheets executed later in a Ruleflow. The concept of a Ruleflow is discussed in the *Quick Reference Guide*.

An example of such usage appears in the following figure:

**Figure 113: planWeight Derived and Used in Same Rulesheet**

The screenshot shows a Rulesheet editor window titled 'PlanWeightDerived.ers'. The 'Scope' pane on the left shows a hierarchy: FlightPlan [plan] (yellow icon), approved (blue icon), fuel (blue icon), planWeight (blue icon), aircraft [plane] (blue icon), and cargo [load] (blue icon). The 'Conditions' table has 7 rows (a-g) and 2 columns (0, 1). Row 'a' contains the condition 'plan.planWeight > plane.grossWeight' with '0' empty and '1' containing 'T'. The 'Actions' table has 2 rows (A-B) and 2 columns (0, 1). Row 'A' contains the action 'plan.planWeight = plan.fuel \* 0.13368 \* 50.4 + (load.weight -> sum) + plane.emptyWeight' with '0' empty and '1' containing a checked checkbox. Row 'B' contains the action 'plan.approved' with '0' empty and '1' containing 'F'. The 'Filters' pane on the left shows 3 filters.

Scope		Conditions		0	1
FlightPlan [plan]		a	plan.planWeight > plane.grossWeight		T
approved		b			
fuel		c			
planWeight		d			
aircraft [plane]		e			
cargo [load]		f			
		g			
Filters		Actions		0	1
1			Post Message(s)		
2		A	plan.planWeight = plan.fuel * 0.13368 * 50.4 + (load.weight -> sum) + plane.emptyWeight	<input checked="" type="checkbox"/>	
3		B	plan.approved		F

In Condition row a, `planWeight` is compared to the aircraft's `grossWeight` to make sure the aircraft is not overloaded. An overloaded aircraft must not be allowed to fly, so the `approved` attribute is assigned a value of `false`.

This has the advantage of being both clear and easy to reuse – the term `planWeight`, once derived, may be used anywhere to represent the data produced by the calculation. It is also much simpler and cleaner to use a single attribute in a rule expression than it is a long, complicated equation.

But this does not mean that the equation cannot be modeled in a Conditional expression, if preferred. The example shown in the figure below places the calculation in the LHS of the Conditional comparison to derive `planWeight` and compare it to `grossWeight` all in the same expression.

**Figure 114: A Calculation in a Conditional Expression**

The screenshot shows a Rulesheet editor window titled 'CalculationAsAConditionalExpression.ers'. The 'Scope' pane on the left is identical to Figure 113. The 'Conditions' table has 7 rows (a-g) and 2 columns (0, 1). Row 'a' contains the condition 'plan.planWeight = plan.fuel \* 0.13368 \* 50.4 + (load.weight -> sum) + plane.emptyWeight' with '0' empty and '1' containing 'T'. The 'Actions' table has 2 rows (A-B) and 2 columns (0, 1). Row 'A' contains the action 'plan.approved' with '0' empty and '1' containing 'F'. The 'Filters' pane on the left shows 2 filters.

Scope		Conditions		0	1
FlightPlan [plan]		a	plan.planWeight = plan.fuel * 0.13368 * 50.4 + (load.weight -> sum) + plane.emptyWeight		T
approved		b			
fuel		c			
planWeight		d			
aircraft [plane]		e			
cargo [load]		f			
		g			
Filters		Actions		0	1
1			Post Message(s)		
2		A	plan.approved		F

This approach might be preferable if the results of the calculation were not expected to be reused, or if adding an attribute like `planWeight` to the Vocabulary were not possible. Often, attributes like `planWeight` are very convenient "intermediaries" or "holders" to carry calculated values that will be used in other rules in a Rulesheet. In cases where such attributes are conveniences only, and are not used by external applications consuming a Rulesheet, they may be designated as "extended transient" attributes in the Vocabulary, which causes their icons to change from blue/yellow to orange/yellow. More details on extended transient attributes are included in [Extended transients in the vocabulary](#) of this manual.

## Calculation as an assignment in an action

Figure 115: A Calculation in an Action Expression

This figure shows two rules that each make an assignment to `maxFuel`, depending on the type of aircraft. In rule 1, the `maxFuel` load for 747s is derived by subtracting `maxCargoWeight` and `emptyWeight` from `grossWeight`. In rule 2, `maxFuel` for DC-10s is simply assigned the literal value 100,000.

## Unsupported uses of calculation expressions

### Calculations in value sets and column cells

The Conditional expression shown below is not supported by Studio, even though it does not turn red. Some simpler equations may actually work correctly when inserted in the Values cell or a rule column cell, but it's a dangerous habit to get into because more complex equations generally do not work. It's best to express equations as shown in the previous sections.

Figure 116: Calculation in a Values Cell and Column

## Calculations in rule statements

While it is possible to embed *attributes* from the Vocabulary inside Rule Statements, it is not possible to embed equations or calculations in them. Operators and equation syntax not enclosed in curly brackets { . . } are treated like all other characters in the Rule Statement – nothing will be calculated. If the Rule Statement shown in the following figure is posted by an Action in rule 1, the message will be displayed exactly as shown; it will not calculate a result of any kind.

**Figure 117: Calculation in a Rule Statement**

Rule Statements				
Rule Messages				
Ref	ID	Post	Alias	Text
1				2 * 3 + 4

Likewise, including equation syntax *within* curly brackets along with other Vocabulary terms is also not permitted. Doing so may cause your text to turn red, as shown:

**Figure 118: Embedding a Calculation in a Rule Statement**

Rule Statements				
Rule Messages				
Ref	ID	Post	Alias	Text
1				The value of maxFuel squared is {plane.maxFuel ** 2}
				problem parsing:The value of maxFuel squared is {plane.maxFuel ** 2}:Invalid Token: **

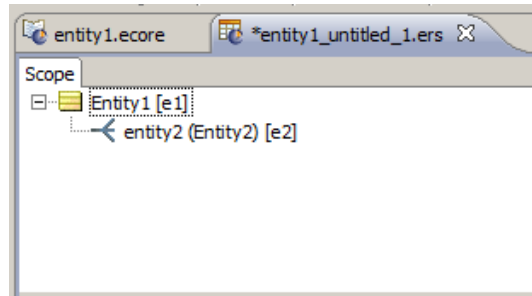

However, even if the syntax does not turn red, you should still not attempt to perform calculations in Rule Statements – it may cause unexpected behavior. When red, the tool tip should give you some guidance as to why the text is invalid. In this case, the exponent operator (\*\*) is not allowed in an embedded expression.

## Test yourself - questions – rules containing calculations and equations

**Note:** Try this test, and then go to **Answers:** [Rules containing calculations & equations](#) on page 285 to correct yourself.

- What are the two possible meanings of the equals operator =? In which sections of the Rulesheet is each of these meanings applicable?
- What is the result of each of the following equations?
  - $10 + 20 / 5 - 4$  \_\_\_\_
  - $2 * 4 + 5$  \_\_\_\_
  - $10 / 2 * 6 - 8$  \_\_\_\_
  - $2 ** 3 * (1 + 2)$  \_\_\_\_
  - $-5 * 2 + 5 * 2$  \_\_\_\_
- Is the following assignments expression valid? Why or why not? Entity1.integer1 = Entity1.decimal1

4. What is the data type of each of the following expressions based on the scope shown below?

- e1.dateTime1.year \_\_\_\_
  - e1.string1.toUpperCase \_\_\_\_
  - e2 -> forAll (integer1 = 10) \_\_\_\_
  - e2.decimal1 -> avg \_\_\_\_
  - e1.boolean1 \_\_\_\_
  - e1.decimal1 > e1.decimal2 \_\_\_\_
  - e2.string2.contains('abc') \_\_\_\_
5. Write "valid" or "invalid" for each of the following assignments
- e1.decimal1 = e2.integer1 \_\_\_\_
  - e2.decimal2 = e2.string2 \_\_\_\_
  - e1.integer1 = e2.dateTime1.day \_\_\_\_
  - e2.integer1 = e2 -> size \_\_\_\_
  - e1.boolean2 = e2 -> exists (string1 = 'abc') \_\_\_\_
  - e2.boolean2 = e1.string1.toBoolean \_\_\_\_
  - e1.boolean2 = e2 -> isEmpty \_\_\_\_
6. The part of Corticon Studio that checks for syntactical problems is called the \_\_\_\_.
7. True or False. If an expression typed in Corticon Studio does not turn red, then the expression is guaranteed to work as expected.
- Referring to the following illustration, answer questions 8 through 10:

The screenshot shows the Corticon Rulesheet interface. On the left, the 'Scope' pane shows a tree structure: 'Movie [film]' containing 'Filters', 'yearReleased', 'dvd (DVD) [aDVD]', and 'quantityAvailable'. Below it, the 'Filters' pane shows a list of filters, with the first one being 'today.year - film.yearReleased > 10'. The main area is divided into 'Conditions' and 'Actions' sections. The 'Conditions' section has a table with columns 0, 1, and 2. Row 'a' contains the condition 'aDVD.quantityAvailable -> sum / aDVD->size' in column 0, and '<= 50000' in column 1, and '> 50000' in column 2. The 'Actions' section has a table with columns A, B, C, D, and E. Row 'A' contains 'Post Message(s)' in column A, and a yellow envelope icon in column B and column E. The 'Overrides' section is at the bottom.

		0	1	2
a	aDVD.quantityAvailable -> sum / aDVD->size	-	<= 50000	> 50000
b				
c				
d

Overrides

8. What does Filters row 1 test?
9. What does Conditions row "a" test? Is there a simpler way to accomplish this same thing using a different operator available in the *Corticon* Rule Language?
10. Write a Rule Statement for rule column 1. (Assume that the only action required for this rule is to post a Warning message as shown.)
11. True or False. The following sections of the Rulesheet accept equations and calculations:
  - Scope \_\_\_\_
  - Rule Statements \_\_\_\_
  - Condition rows \_\_\_\_
  - Action rows \_\_\_\_
  - Column 0 \_\_\_\_
  - Condition cells \_\_\_\_
  - Action cells \_\_\_\_
  - Filters \_\_\_\_

## Rule dependency: Chaining and looping

---

For details, see the following topics:

- [What is rule dependency?](#)
- [Forward chaining](#)
- [Rulesheet processing: modes of looping](#)
- [Looping controls in Corticon Studio](#)
- [Looping example](#)
- [Using conditions as a processing threshold](#)
- [Test yourself - questions – Rule dependency: chaining and looping](#)

### What is rule dependency?

Dependencies between rules exist when a Conditional expression of one rule evaluates data produced by the Action of another rule. The second rule is said to be "dependent" upon the first.

## Forward chaining

The first step in learning to use looping is to understand how it differs from normal inferencing behavior of executing rules, whether executed by Corticon Studio or Corticon Server. When a Rulesheet is compiled (either by Corticon Studio during a Ruletest execution, or by Corticon Server during deployment), a *dependency network* for the rules is automatically generated. Corticon Studio and Corticon Server use this network to determine the order in which rules fire in runtime. For example, in the simple rules below, the proper dependency network is 1 > 2 > 3 > 4.

1. If value = A, then set value = B
2. If value = B, then set value = C
3. If value = C, then set value = D
4. If value = D, then set value = B

This is not to say that all three rules will always *fire* for a given test – clearly a test with B as the initial value will only cause rules 2, 3, and 4 to fire. But the dependency network ensures that rule 1 is always *evaluated* before rule 2, and rule 2 is always *evaluated* before rule 3, and so on. This mode of Rulesheet execution is called **Optimized Inferencing**, meaning the rules execute in the optimal sequence determined by the dependency network generated by the compiler. **Optimized Inferencing** is the default mode of rule processing for all Rulesheets.

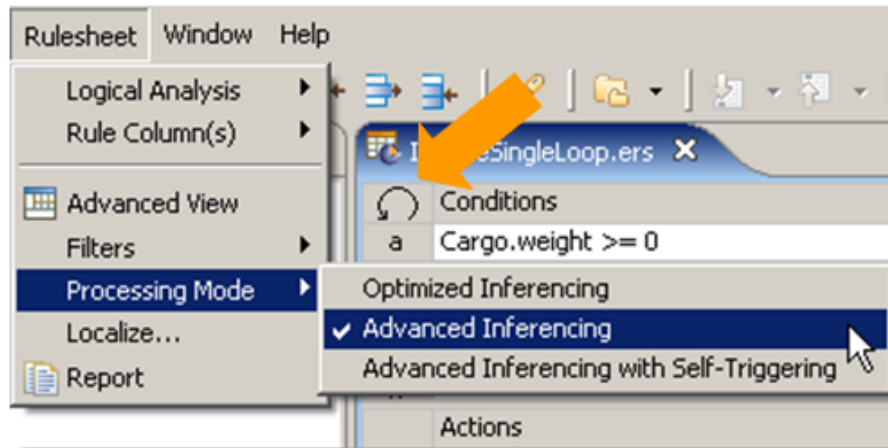

Optimized Inferencing processing is a powerful capability that enables the rule modeler to "break up" complex logic into a series of smaller, less complex rules. Once broken up into smaller or simpler rules, the logic will be executed in the proper sequence automatically, based on the dependencies determined by the compiler.

An important characteristic of Optimized Inferencing processing: the flow of rule execution is single-pass, meaning a rule in the sequence is evaluated once and never revisited, even if the data values (or data "state") evaluated by its Conditions change over the course of rule execution. In our example above, this effectively means that rule execution ceases after rule 4. Even if rule 4 fires (with resulting value = B ), the second rule **will not** be revisited, re-evaluated, or re-fired even though its Condition (If value = B) would be satisfied by the current value (state). We can *force* rule 2 to be re-evaluated only if a one of Corticon Studio's looping processing modes is enabled for the Rulesheet. Remember, just because sequential processing occurs automatically does not mean looping will occur too. Looping and its enablement are discussed next.

## Rulesheet processing: modes of looping

Occasionally, we *want* rules to be re-evaluated and re-fired (if satisfied). This scenario requires the Corticon rule engine to make multiple passes through the same Rulesheet. We call this behavior *advanced inferencing*, and to enable it in Rulesheet execution, we must set Rulesheet processing mode to **Advanced Inferencing** by selecting **Rulesheet > Processing Mode > Advanced Inferencing** from the Studio menubar, as shown:

**Figure 119: Selecting Advanced Inferencing Processing Mode for a Rulesheet**

Also note the circular icon to the immediate left of the Conditions header (see **orange arrow**).

If the rule engine is permitted to loop through the rules above, the following events occur:

Given a value of A as the initial data, the Condition in rule 1 will be satisfied and the rule will fire, setting the value to B. The 2<sup>nd</sup> rule's Condition is then satisfied, so the value will advance (or be reset) to C, and so on, until the value is once again B after the 4<sup>th</sup> rule fires. Up to this point, the rule engine is exhibiting standard, Optimized Inferencing behavior.

Now here's the new part: the value (state) has changed since the 2<sup>nd</sup> rule last fired, so the rule engine will re-evaluate the Condition, and, finding it satisfied, will fire the 2<sup>nd</sup> rule again, advancing the value to C. The 3<sup>rd</sup> rule will also be re-evaluated and re-fired, advancing the value to D, and so on. This sequence is illustrated in the following figure.

**Figure 120: Loop Iterations**

step #	Input value	Rule fired	Output value	Loop Iteration
1	A	1	B	
2	B	2	C	
3	C	3	D	
4	D	4	B	
5	B	2	C	1
6	C	3	D	
7	D	4	B	
8	B	2	C	2
9	C	3	D	
10	D	4	B	
...	...	...	...	...

Here's the key to understanding looping: when a looping processing mode is enabled, rules will be continually re-evaluated and re-fired in a sequence determined by their dependency network as long as data state has changed since their last firing. Once data state no longer changes, looping will cease.

Notice that the last column of the table indicates the number of loop iterations – the first loop does not begin until rule 2 fires for the *second* time. The first time through the rules (steps 1-4) does not count as the first loop iteration because the loop does not actually start until step 5.

## Types of loops

### Infinite Loops

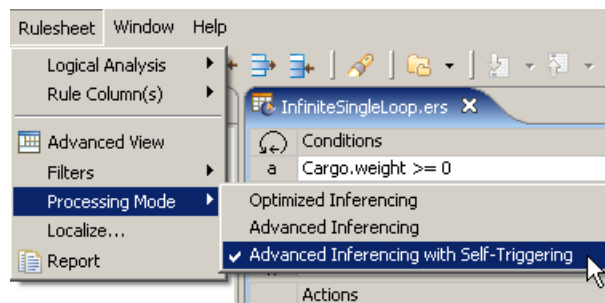

In the example above, looping between rules 2, 3 and 4 continues indefinitely because there is nothing to stop the cycle. Some loops, especially those inadvertently introduced, are not self-terminating. Because these loops will not end by themselves, they are called infinite loops. Infinite loops can be especially vexing to a rule modeler because it isn't always apparent when a Rulesheet has entered one. A good indication, however, is that rule execution takes longer than expected to complete! A special control is provided to prevent infinite loops. This control is described in the [Terminating Infinite Loops](#) section, below.

### Trivial Loops

Single-rule loops, or loops caused by rules that depend logically on themselves, are also known as "trivial loops". We consider single-rule loops to be a special kind of loop because they consist of just a single rule that successively revisits, or "triggers", itself.

To enable the self-triggering mode of looping, we must select **Rulesheet > Processing Modes > Advanced Inferencing with Self-Triggering** from the Corticon Studio menubar, as shown in

**Figure 121: Selecting Advanced Inferencing with Self-Triggering Processing Mode for a Rulesheet**

Notice the icon to the left of the Conditions header - it contains the additional tiny arrow, which indicates self-triggering is active.

Here's an example of a loop created by a self-triggering rule:

**Figure 122: Example of an Infinite Single-Rule Loop**

Let's trace this rule to make sure we understand how it works.

When `Cargo.weight` has a value equal to or greater than 0, then rule 1 fires and the value of `Cargo.weight` is incremented by 1. Data state has now *changed*, in other words, the value of at least one of the attributes has changed. In this case, it's the value of `Cargo.weight` which has changed.

Because it was rule 1 execution that *caused* the data state change, and since self-triggering is enabled, the same rule 1 will be re-evaluated. Now, if the value of `Cargo.weight` satisfied the rule initially, it certainly will do so again, so the rule fires again, and self-triggers again. And so on, and so on. This is also an example of an infinite loop, because no logic exists in this rule to prevent it from continuing to loop and fire.

## An Exception to Self-Triggering

Self-triggering logic can also be modeled in Column 0 of the Rulesheet, as shown:

**Figure 123: Example of an Infinite Loop created by a Self-Triggering Rule**

But this figure is also a good example of why it might be appropriate to disable self-triggering processing: we only want the `weight` to increment once, not enter into an infinite loop, which it would otherwise do, unconditionally! This is a special case where we have intentionally prevented this rule from iterating, even though self-triggering is enabled. This rule will execute only once, regardless of looping processing mode.

Another example of a loop caused by self-triggering rule, but one which is not infinite, is shown below. The behavior described only occurs when Rulesheet processing mode is set to **Advanced Inferencing with Self-Triggers** :

**Figure 124: Example of a Finite Single-Rule Loop**

		0	1
<b>Conditions</b>			
a	Cargo.weight	-	0..20
b			
c			
<b>Actions</b>			
Post Message(s)			
A	Cargo.weight += 1		<input checked="" type="checkbox"/>
B			

In the figure above, the rule continues to fire until `Cargo.weight` reaches a value of 21, whereupon it fails to satisfy the Condition, and firing ceases. The loop terminates with `Cargo.weight` containing a final value of 21.

It's important to note that in all three examples, an initial `Cargo.weight` value of 0 or higher was necessary to "activate" the loop. A negative (or null) value, for example, would not have satisfied the rule's Condition and the loop would not have begun at all.

## Multi-rule Loops

As the name suggests, multi-rule loops exist when 2 or more rules are mutually dependent. As with single-rule loops, the Rulesheet containing the looping rules must be configured to process them. This is accomplished as before. Choose **Rulesheet > Processing Mode > Advanced Inferencing** from the Studio menubar, as shown previously in [Selecting Advanced Inferencing Processing Mode for a Rulesheet](#).

Here's an example of a multi-rule logical loop:

**Figure 125: Example of a Finite Multi-Rule Loop**

		0	1	2	3
<b>Conditions</b>					
a	Cargo.weight	-	1..10	-	> 10
b	Cargo.volume > 0	-	-	T	-
-					
<b>Actions</b>					
Post Message(s)					
A	Cargo.volume = Cargo.weight * 2		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
B	Cargo.weight += 1			<input checked="" type="checkbox"/>	
C					
Overrides					

Ref	ID	Post	Alias	Text
1		Info	Cargo	If weight is between 0 and 10 [{Cargo.weight}] then volume is twice weight [{Cargo.volume}]
2		Warning	Cargo	As long as volume is greater than 0, increment weight by 1 [now{Cargo.weight}]
3		Violation	Cargo	weight has exceeded the threshold, so the loop terminates

In the figure above, rule 2 is dependent upon rule 1, and rule 1 is dependent upon rule 2. We've also added a rule 3, which does not participate in the 1—2 loop, but will generate a nice `Violation` message when the 1—2 loop finally terminates. Note, rule 3 does not *cause* the 1—2 loop to terminate, it just *announces* that the loop has terminated. Let's test these rules and see how they behave. In **Ruletest for the Multi-rule Rulesheet**, we see a simple Ruletest.

**Figure 126: Ruletest for the Multi-rule Rulesheet**

We're providing a starting value of `Cargo.weight` just to get the loop going. According to the Condition in rule 1, this value needs to be between 1 and 10 (inclusive).

**Figure 127: Ruletest for the Multi-rule Rulesheet**

Severity	Message	Entity
Info	If weight is between 0 and 10 [1] then volume is twice weight [=2.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=2.000000]	Cargo[1]
Info	If weight is between 0 and 10 [2.000000] then volume is twice weight [=4.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=3.000000]	Cargo[1]
Info	If weight is between 0 and 10 [3.000000] then volume is twice weight [=6.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=4.000000]	Cargo[1]
Info	If weight is between 0 and 10 [4.000000] then volume is twice weight [=8.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=5.000000]	Cargo[1]
Info	If weight is between 0 and 10 [5.000000] then volume is twice weight [=10.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=6.000000]	Cargo[1]
Info	If weight is between 0 and 10 [6.000000] then volume is twice weight [=12.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=7.000000]	Cargo[1]
Info	If weight is between 0 and 10 [7.000000] then volume is twice weight [=14.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=8.000000]	Cargo[1]
Info	If weight is between 0 and 10 [8.000000] then volume is twice weight [=16.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=9.000000]	Cargo[1]
Info	If weight is between 0 and 10 [9.000000] then volume is twice weight [=18.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=10.000000]	Cargo[1]
Info	If weight is between 0 and 10 [10.000000] then volume is twice weight [=20.000000]	Cargo[1]
Warning	As long is volume is greater than 0, increment weight by 1 [now=11.000000]	Cargo[1]
Violation	weight has exceeded the threshold, so the loop terminates	Cargo[1]

When intentionally building looping rules, it is often helpful to post messages with embedded attribute values (as shown in the Rule Statements section of [Figure 125](#) on page 144) so we can trace the loop's operation and verify it is behaving as expected. It should be clear to the reader that the Ruletest shown in **Ruletest for the Multi-rule Rulesheet** contains the expected results.

## Looping controls in Corticon Studio

To handle the various aspects of rule looping, Corticon Studio provides several mechanisms for identifying and controlling looping behavior.

Although we've only shown simple examples so far, looping rules can get much more complicated. Sometimes, rules have mutual dependencies by accident – we didn't intend to include loops when we built the Rulesheet. It is for this reason that all loop processing is disabled by default (in other words, the default Rulesheet processing mode is Optimized Inferencing, which does not permit revisiting rules that have already been evaluated once). We must manually enable the loop processing mode of our choice to cause the loops to execute. This is the strongest, most fool-proof mechanism for preventing unexpected looping behavior – simply keep loop processing disabled.

### Identifying loops

Assuming we haven't intentionally incorporated looping logic in our Rulesheet, then we need a way to discover if unintentional loops occur in our rules.

### The loop detection tool

To help identify inadvertent loops, Corticon Studio provides a **Check for Logical Loops** tool in the Corticon Studio toolbar. The tool contains a powerful algorithm that analyzes dependencies between rules on the same Rulesheet, and reports discovered loops to the rule modeler. For the Loop Detector to notice mutual dependencies, a Rulesheet must have looping enabled using one of the choices described earlier.

Clicking the **Check for Logical Loops** icon displays a window that describes the mutual dependencies found on the Rulesheet. To illustrate loop detection, we will use a few of the same examples from before.

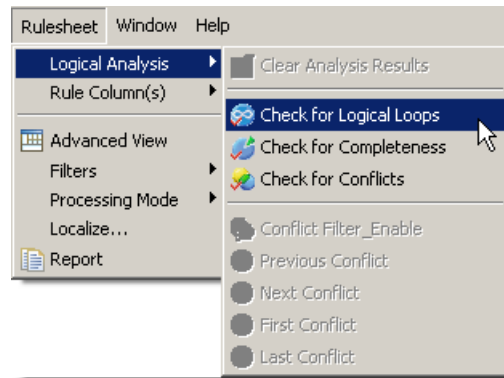

**Figure 128: Example of an Infinite Single-Rule Loop**

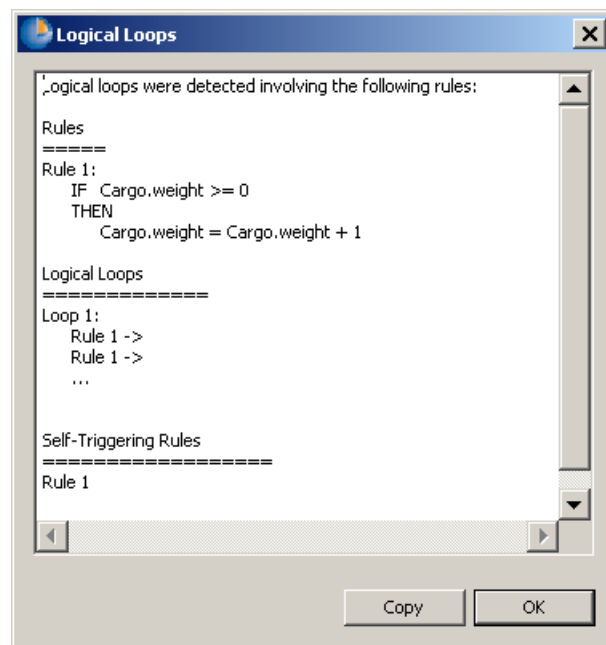

Conditions		0	1
a	Cargo.weight >= 0	-	T
b			
c			
Actions			
Post Message(s)			
A	Cargo.weight += 1		<input checked="" type="checkbox"/>

When applied to a Rulesheet containing just the single-rule loop shown in this figure, the **Check for Logical Loops** tool displays the following window:

**Figure 129: Checking for Logical Loops in a Rulesheet**

**Figure 130: A Single-Rule Loop Detected by the Check for Logical Loops Tool**

The Check for Logical Loops tool first lists rules where mutual dependencies exist. Then, it lists the distinct, independent loops in which those rules participate, and finally it lists where self-triggering rules exist (if any). In this simple single-rule loop example, only one rule contains a mutual dependency, and only one loop exists in the Rulesheet.

Note that the Check for Logical Loops tool does not automatically fix anything, it simply points out to us that our rules have loops, and gives us an opportunity to remove or modify the offending logic.

## Removing loops

If the Check for Logical Loops tool detects loops, we can take one of several corrective actions:

- If no loops are what you want, then click **Rulesheet > Processing Mode** and de-select whichever of the two looping options is currently selected. Once done, the **Check for Logical Loops** tool will no longer detect loops and the software will no longer process them.
- If loops are what you want, then take measures to ensure that none of the loops can be infinite. Normally, this means adding conditional logic to one of the looping rules to make sure that the rule can't be satisfied indefinitely. This is similar to the bounding of Condition 1 in [Example of a Finite Multi-Rule Loop](#) using a Values set of 0..20. Once `Cargo.weight` reaches 21, the rule's Condition will no longer be satisfied and the loop will terminate.
- If some loops are good and some are not, then remove the inter-dependencies in the unwanted loops and ensure the selected loops are not infinite.

## Terminating infinite loops

By definition, infinite loops won't terminate by themselves. Therefore, Corticon provides a "safety valve" setting described in the *Server Integration & Deployment Guide*.

`com.corticon.reactor.rulebuilder.maxloop` is a property that caps the number of iterations allowed before the system automatically terminates a loop. The default setting is 100, meaning that a loop is allowed to iterate up to 100 times normally. Once the number of loops exceeds the `maxloop` setting, then the system automatically terminates the loop and generates a `Violation` error message. This means that the final number of loop iterations will be 101: 100 normal iterations plus the final iteration that causes the `Violation` message to appear and the loop to terminate. The `Violation` message is shown below:

**Figure 131: Maxloop Exceeded Violation Message**

If you are comfortable writing looping rules, and want the software to be able to loop more than 100 times, be sure to reset this property to a higher value. Keep in mind that the more iterations the system performs, the longer rule execution may take. If the Rulesheets you intend to deploy require high iteration counts, be sure to inform your deployment manager so he/she can configure the target Corticon Server with a higher `maxloop` cap.

## Looping example

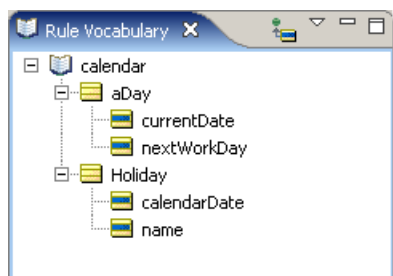

### Problem

For any given day of the week, determine the next working day. Take into consideration weekends and holidays.

## Solution

Implemented correctly in Corticon Studio, these rules should start with a given input date, and increment as necessary until the next workday is identified (workday defined here as any day *not* Saturday, Sunday, or a national holiday). A simple Vocabulary that supports these rules is shown in [Example of a Finite Single-Rule Loop](#).

**Figure 132: Sample Vocabulary for Holiday Rules**

Next, the rules are implemented in the Rulesheet shown in the following figure:

**Figure 133: Sample Rulesheet for Determining Next Workday**

nextDay2.ers							
Conditions		0	1	2	3	4	5
a	aDay.nextWorkDay = Holiday.calendarDate	-	T	F	-	-	-
b	aDay.nextWorkDay.dayOfWeek	-	-	-	1	7	other
c							
Actions							
Post Message(s)							
A	aDay.nextWorkDay = aDay.currentDate.addDays(1)						
B	aDay.nextWorkDay = aDay.nextWorkDay.addDays(1)	<input checked="" type="checkbox"/>			<input checked="" type="checkbox"/>		
C	aDay.nextWorkDay = aDay.nextWorkDay.addDays(2)		<input checked="" type="checkbox"/>			<input checked="" type="checkbox"/>	
D							<input checked="" type="checkbox"/>
Overrides							

Rule Statements		Rule Messages	
Ref	Post	Alias	Text
0	Info	aDay	Today is [{aDay.currentDate}] and the next day is [{aDay.nextWorkDay}]
1	Warning	aDay	The next day falls on a holiday, so increment to the next day [{aDay.nextWorkDay}]
2	Info	aDay	The next day does not fall on a holiday, so do not increment
3	Warning	aDay	The next day falls on a Sunday, so increment to the next day to [{aDay.nextWorkDay}]
4	Warning	aDay	The next day falls on a Saturday, so increment two days to [{aDay.nextWorkDay}]
5	Info	aDay	The next day does not fall on a Saturday or Sunday, so do not increment

Let's step through this Rulesheet.

1. First, notice that the Scope section wasn't used. We're using a very simple Vocabulary with short entity names and no associations, so aliases aren't necessary. Furthermore, none of our rules use collection operations, so aliases representing collections aren't required either.
2. The first rule executed is the Nonconditional equation (in Condition/Action column 0) setting `nextWorkDay` equal to `currentDate` plus one day.
3. Rule 1 (in column 1) checks to see if the `DateTime` of the `nextWorkDay` matches any of the holidays defined in one or more `Holiday` entities. If it does, then the Action row B increments `nextWorkDay` by one day and posts a warning message.
4. Rule 3 checks to see if the `nextWorkDay` falls on a Sunday. Notice that this rule uses the `.dayOfWeek` operator, which is described in full detail in the *Rule Language Guide*. If the day of the week is Sunday (in other words, `.dayOfWeek` returns a value of 1), then the Action increments `nextWorkDay` by one day and posts a Warning message.
5. Rule 4 checks to see if the `nextWorkDay` falls on a Saturday. If the day of the week is Saturday (in other words, `.dayOfWeek` returns a value of 7), then the Action row C increments `nextWorkDay` by two days and posts a Warning message. By incrementing 2 days, we skip an extra iteration because we know Sunday is also a non-workday!

Do not forget to check for conflicts – they do exist in this Rulesheet. However, we will make the assumption that a holiday never falls on a weekend.

**Note:** Resolution of the conflicts is straightforward, so we won't address that in detail here. One conflict – that between rules 1 and 4 - is left unresolved because we have assumed that a holiday never falls on a weekend. See [Logical Analysis](#) chapter more a complete discussion of conflict and other logical problems.

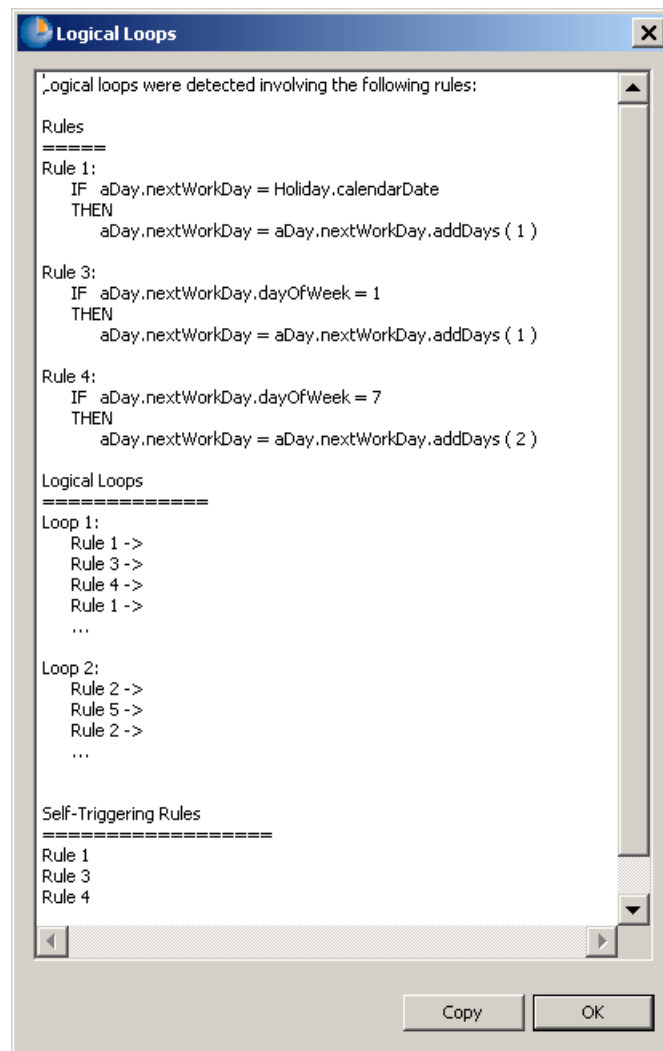

A modified Rulesheet displays the overrides added to resolve the conflicts in the following figure:

**Figure 134: Holiday Rules with Ambiguities Resolved by Overrides**

nextDay2.ers		0	1	2	3	4	5
Conditions							
a	aDay.nextWorkDay = Holiday.calendarDate	-	T	F	-	-	-
b	aDay.nextWorkDay.dayOfWeek	-	-	-	1	7	other
c							
Actions							
Post Message(s)							
A	aDay.nextWorkDay = aDay.currentDate.addDays(1)	<input checked="" type="checkbox"/>					
B	aDay.nextWorkDay = aDay.nextWorkDay.addDays(1)		<input checked="" type="checkbox"/>		<input checked="" type="checkbox"/>		
C	aDay.nextWorkDay = aDay.nextWorkDay.addDays(2)					<input checked="" type="checkbox"/>	
D							
Overrides			5		2	2	
Rule Statements		Rule Messages					
Ref	Post	Alias	Text				
0	Info	aDay	Today is [{aDay.currentDate}] and the next day is [{aDay.nextWorkDay}]				
1	Warning	aDay	The next day falls on a holiday, so increment to the next day [{aDay.nextWorkDay}]				
2	Info	aDay	The next day does not fall on a holiday, so do not increment				
3	Warning	aDay	The next day falls on a Sunday, so increment to the next day to [{aDay.nextWorkDay}]				
4	Warning	aDay	The next day falls on a Saturday, so increment two days to [{aDay.nextWorkDay}]				
5	Info	aDay	The next day does not fall on a Saturday or Sunday, so do not increment				

Using the same rules as before, let's click the **Logical Loop Checker**  icon in the Corticon Studio toolbar. The following window opens:

**Figure 135: Results of Logical Loop Check**

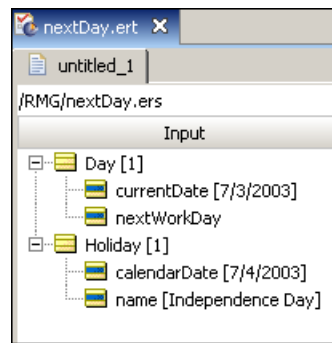

This window first identifies exactly which rules are involved in loops. Secondly, the window outlines the specific attribute interactions that create the loops.

Now that we fully understand the looping logic present in our Rulesheet, let's create a Ruletest to verify that the loops operate as intended and produce the correct business results.

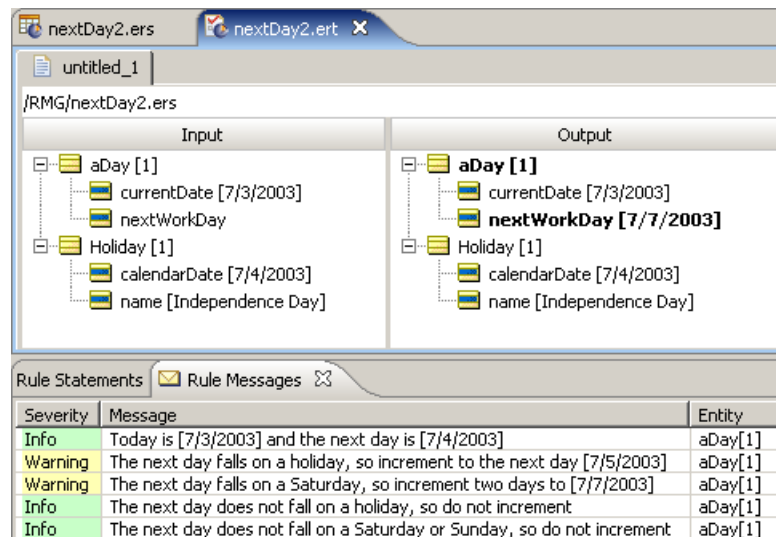

Ruletest for Holiday Rules

**Figure 136: Ruletest for Holiday Rules**

Given the fact that July 4<sup>th</sup>, 2003 falls on a Friday, we expect `nextWorkDay` to contain a final value of July 7<sup>th</sup>, 2003 – a Monday – when the loops terminate. Running the Ruletest:

**Figure 137: Ruletest for Holiday Rules**

As you can see in this figure, the expected result is obtained.

## Using conditions as a processing threshold

We want to distinguish looping, which involves revisiting, re-evaluating, and possible re-firing rules, and which requires you to enable one of the looping modes discussed above, from another behavior that may appear similar on the surface.

You have almost certainly noticed Corticon's inherent ability to process multiple test scenarios at once. For example, a rule written using the Vocabulary term `Cargo.weight` will be evaluated (and potentially fired) for every instance of `Cargo` encountered during execution. If a Ruletest contains 4 `Cargo` entities, then the rule engine will test the rule's conditions with each of them. If any of the `Cargo` entities satisfy the rule's conditions, then the rule will fire. This could mean that the rule fires once, twice, or up to four times, depending on the actual data values of each `Cargo`. We know from our prior discussion of Scope that a rule will evaluate *all* data that shares the same scope as the rule itself.

This iterative behavior is a natural part of the Corticon rule engine design – there's nothing special we need to do to enable it or "turn it on". Note, that this behavior is different from the modes of looping discussed above because the `Cargo.weight` rule is not re-evaluated for a given piece of data. Rule execution is still single-pass. It is just that it makes a single pass through *each* of the 4 `Cargo` entities.

The advantage of this natural iteration is that we don't need to force it – the rule engine will automatically process all data that shares the same scope as the rule. If the Ruletest contains 4 Cargos, the rule will be evaluated 4 times. If the Ruletest contains 4000 Cargos, the rule will be evaluated 4000 times. We don't write the rule any differently in Corticon Studio.

But this advantage can also be a disadvantage. What if we *want* rule execution to stop part-way through its evaluation of a given set of entity data (which we call a "binding"). What if, after finding a `Cargo` that satisfies the rule among the set (binding) of `Cargo` entities, we want to *stop* evaluation mid-stream? In normal operation, this is not possible.

Here's a simple example.

**Figure 138: Rulesheet and Ruletest, no threshold condition, CaPT disabled**

Conditions	0	1
a Thing.aSize	-	'small'
b		
c		
d		
e		
f		
Actions		
Post Message(s)		
A Thing.selected		T

Input	Output
Thing [1] aSize [huge]	Thing [1] aSize [huge]
Thing [2] aSize [small]	Thing [2] aSize [small] selected [true]
Thing [3] aSize [small]	Thing [3] aSize [small] selected [true]

In the example above, no threshold condition, CaPT disabled, we see a simple rule that sets `thing.selected = true` for all `thing.aSize = 'small'`. Notice in the adjacent Ruletest, that each small `Thing` is selected. `Thing[2]` and `Thing[3]` are both small, so they are both selected by the rule. The rule has evaluated all three `Things`, but finding only two that satisfy the rule's condition, only fires twice. This iteration happened automatically.

What if we wanted rule execution to stop after finding the first `Thing` that satisfies the rule? In other words, allow the rule engine to fire for `Thing[2]` but stop processing *before* firing for `Thing[3]`. Is that possible? You might think the following Rulesheet would accomplish this goal.

**Figure 139: Rulesheet and Ruletest, threshold condition added, CaPT disabled**

Conditions	0	1
a Thing.selected	-	F
b Thing.aSize	-	'small'
c		
d		
e		
f		
Actions		
Post Message(s)		
A Thing.selected = false		
B Thing.selected		T

Input	Output
Thing [1] aSize [huge]	Thing [1] aSize [huge] selected [false]
Thing [2] aSize [small]	Thing [2] aSize [small] selected [true]
Thing [3] aSize [small]	Thing [3] aSize [small] selected [true]

The example in this figure includes two changes: 1) `Thing.selected` is defaulted to false in the Nonconditional rule (Action row A0). And 2) a second Condition row checks for `Thing.selected = false` as part of rule 1. This is called a "threshold" condition.

You might be tempted to think that when `Thing[2]` fires the rule, its value of `selected` (re-set to `true`) would be sufficient to stop further evaluation and execution of `Thing[3]`. But as we see in the adjacent Ruletest, that this isn't the case. The reason is that `Thing[3]` is an entirely separate entity within the binding, and is entitled to its own evaluation of rule 1 regardless of what happened with `Thing[2]`. The addition of the threshold condition accomplished nothing.

A special feature in Corticon Studio, called **Use Condition as Processing Threshold** (abbreviated as CaPT), allows us to interrupt processing of the binding. You activate this option by selecting the rule column involved, then from the Corticon Studio menu bar, choose **Rulesheet > Rule Columns(s) > Use Condition as Processing Threshold**.

Once selected, CaPT causes the rule column header to display in bold type, as shown below, circled in orange:

**Figure 140: Rulesheet and Ruletest, threshold condition added, CaPT enabled**

	Conditions	0	<b>1</b>	Input	Output
a	Thing.selected	-	F	Thing [1]	Thing [1]
b	Thing.aSize	-	'small'	aSize [huge]	aSize [huge]
c				Thing [2]	selected [false]
d				aSize [small]	Thing [2]
e				Thing [3]	aSize [small]
f				aSize [small]	selected [true]
Actions					
Post Message(s)					
A	Thing.selected = false	<input checked="" type="checkbox"/>	<input type="checkbox"/>		
B	Thing.selected		T		

When CaPT is activated, it breaks out of the automatic binding iteration whenever an instance in the binding fails to satisfy the threshold condition. In this case, Thing[2], having just fired rule 1, no longer satisfies the threshold condition, and causes rule execution to stop before evaluating Thing[3]. If we re-run this Ruletest, we might see Thing[3] evaluated first, in which case rule execution would stop before evaluating Thing[2].

Within a binding, sequence of evaluation of elements is *random* and may change from execution to execution. There is nothing about the binding that enforces an order or sequence among the bound elements.

## Test yourself - questions – Rule dependency: chaining and looping

**Note:** Try this test, and then go to **Answers:** [Rule dependency: dependency & inferencing](#) on page 286 to correct yourself.

1. What is the main difference between inferencing and looping?
2. A loop that does not end by itself is known as an \_\_\_\_\_ loop.
3. A loop that depends logically on itself is known as a single-rule or \_\_\_\_\_ loop.
4. True or False. The **Check for Logical Loops** tool in Corticon Studio will always find mutual dependencies in a Rulesheet if they are present.
5. True or False. The **Check for Logical Loops** tool in Corticon Studio can fix inadvertent loops.

Referring to the following illustration, answer questions 6 through 8

DVD_Inventory.ers				
Conditions				
	0	1	2	
a	DVD.priceTier	'High'	'Medium'	
b	DVD.quantityAvailable	> 100000	-	
c	DVD.releaseDate > today.addMonths(-6)	-	T	
d				
Actions				
Post Message(s)				
A	DVD.priceTier	'Medium'		
B	DVD.quantityAvailable += 25000			
Overrides				
Rule Statements				
Ref	ID	Post	Alias	Text
1		Warning	DVD	If DVD price tier is High and > 100,000 copies are available, change price tier to medium to decrease inventory
2		Info	DVD	If DVD price tier is Medium and DVD < 6 months old, then increase inventory by 25,000 copies to meet expected demand

6. Given these two rules, is it necessary for the Rulesheet to use the Inferencing mode shown? Why or why not?
7. Is there any potential harm in having this Rulesheet configured to Advanced Inferencing with Self-Triggering? Why or why not?
8. If the Rulesheet as shown above were tested with a DVD having a price tier of *High*, quantity available of 150,000, and release date within the past 6 months, what would be the outcome of the test?
9. This icon indicates which type of inferencing is enabled for this Rulesheet?

10. This icon indicates which type of inferencing is enabled for this Rulesheet?

11. A \_\_\_\_\_ determines the sequence of rule execution and is generated when a Rulesheet is \_\_\_\_\_.

---

# Filters & preconditions

---

Conditional expressions modeled in the **Filters** section of a Rulesheet can behave in two different ways: as filters alone or as filters *plus* preconditions. Both behaviors are explained and illustrated in this chapter.

Henceforth, we will refer to any conditional expression entered in the **Filters** window of a Rulesheet generically as a Filter, regardless of its strict mode of behavior. This will help us to differentiate the expression itself from its specific behaviors.

This chapter uses the automotive insurance Vocabulary example first introduced in the [Collections](#) chapter.

---

**Note:** This topic is directly related to the Rulesheet's **Database Filter** functionality. When you are set to Integration and Deployment mode, the Enterprise Data Connector (EDC) enables this toggle. When cleared, it is a filter that is applied to the data currently in working memory. When checked, the filter is a database query that can retrieve data from the database which is then added to working memory.

---

For details, see the following topics:

- [What is a filter?](#)
- [What is a precondition?](#)
- [Using collection operators in a filter](#)
- [Multiple filters on collections](#)
- [Filters that use OR](#)
- [Test yourself - questions – filters & preconditions](#)

## What is a filter?

A Filter expression acts to limit or reduce the data in working memory to only that subset whose members satisfy the expression. A Filter *does not* permanently remove or delete any data; it simply *excludes* data from evaluation by other rules in the same Rulesheet.

We often say that data satisfying a Filter expression "survives" the Filter. Data that does not survive the Filter is said to be "filtered out". Data that has been filtered out is *ignored* by other rules in the same Rulesheet.

A Filter expression, no matter what its full behavior, Rulesheets are unaffected by Filter expressions in other Rulesheets.

As an example, look at the Rulesheet sections shown in the following two figures:

**Figure 141: Aliases Declared**

The **Scope** window in this figure defines aliases for a root-level `Policy` entity, a collection of `Driver` entities related to that `Policy`, and a collection of `Vehicle` entities related to that `Policy`, named `thePolicy`, `drivers`, and `cars`, in that order.

To start with, we will write a simple Filter and observe its default behavior. In the simple scenario below, the Filter expression reduces the set of data acted upon by the Nonconditional rule (column 0), which in this case merely posts the Rule Statement as a message.

**Figure 142: Rulesheet to Illustrate Basic Filter Behavior**

The screenshot shows the Corticon Rulesheet editor with three tabs: 'autoClaim.ecore', 'BasicFilters.ers', and '\*BasicFilters.ert'. The 'BasicFilters.ers' tab is active, displaying a rule configuration for 'Policy [thePolicy]'. The 'Scope' pane on the left shows a tree structure: 'Policy [thePolicy]' contains 'Filters' (with a filter 'drivers.age > 16') and 'startDate'. 'driver (Driver) [drivers]' contains 'Filters' (with a filter 'drivers.age > 16') and 'age' and 'name'. 'vehicle (Vehicle) [cars]' is also listed. The 'Filters' pane shows a list of filters, with '1 drivers.age > 16' selected. The 'Conditions' pane shows a list of conditions (a through l). The 'Actions' pane shows 'Post Message(s)' with a checkmark. The 'Overrides' pane is empty. The 'Rule Statements' pane shows a table with one row: '0 Age Info drivers Driver name {drivers.name} is older than 16'.

Ref	ID	Post	Alias	Text
0	Age	Info	drivers	Driver name {drivers.name} is older than 16

Our result is not unexpected: for every element in the collection (every `Driver`) whose `age` attribute is greater than 16, we see a posted message in the Ruletest, as shown below:

**Figure 143: Ruletest to test Filter Behavior**

The screenshot shows the Ruletest interface with the following components:

- Input Panel:**
  - Policy [1]
    - startDate
    - driver (Driver) [1]
      - age [18]
      - name [Jacob]
    - driver (Driver) [2]
      - age [14]
      - name [John]
    - driver (Driver) [3]
      - age [21]
      - name [Lisa]
- Output Panel:**
  - Policy [1]
    - startDate [03/25/13]
    - driver (Driver) [1]
      - age [18]
      - name [Jacob]
    - driver (Driver) [2]
      - age [14]
      - name [John]
    - driver (Driver) [3]
      - age [21]
      - name [Lisa]
- Rule Messages Table:**

Severity	Message
Info	Driver name Lisa is older than 16
Info	Driver name Jacob is older than 16

The policy is issued because there are drivers over 16. But because only `Jacob` and `Lisa` are older than 16, Rule Messages are posted only for them.

## Full filters

By default, each Filter you write acts as a *full* filter. This means not only will the data not satisfying the Filter be filtered out of subsequent evaluations, but in cases where this data comprises a collection where no elements survive the Filter, *the parent entity will also be filtered out!*

Here is the Testsheet with three juvenile drivers:

**Figure 144: Ruletest for Full Filter**

Input	Output
<ul style="list-style-type: none"> <li>Policy [1] <ul style="list-style-type: none"> <li>startDate</li> <li>driver (Driver) [1] <ul style="list-style-type: none"> <li>age [13]</li> <li>name [Jacob]</li> </ul> </li> <li>driver (Driver) [2] <ul style="list-style-type: none"> <li>age [14]</li> <li>name [John]</li> </ul> </li> <li>driver (Driver) [3] <ul style="list-style-type: none"> <li>age [10]</li> <li>name [Lisa]</li> </ul> </li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>Policy [1] <ul style="list-style-type: none"> <li>startDate</li> <li>driver (Driver) [1] <ul style="list-style-type: none"> <li>age [13]</li> <li>name [Jacob]</li> </ul> </li> <li>driver (Driver) [2] <ul style="list-style-type: none"> <li>age [14]</li> <li>name [John]</li> </ul> </li> <li>driver (Driver) [3] <ul style="list-style-type: none"> <li>age [10]</li> <li>name [Lisa]</li> </ul> </li> </ul> </li> </ul>

Notice two important things about this Ruletest's results: first, none of the `Driver` entities in the Input are older than 16, which means none of them survives the Filter. Second, because the parent `Policy` entity does not contain at least one `Driver` which satisfies the Filter, then the parent `Policy` itself also fails to survive the Filter. If no `Policy` entity survives the Filter, then rule Column 0 has no data upon which to act, so no `Policy` is assigned a `startDate` equal to `today`. The Testsheet's Output, shown in the figure above, confirms the behavior.

Why would we want a Filter to behave this way? Perhaps because, if these are the only drivers seeking a policy, there must be at least one driver of legal age to warrant issuing a policy. While you will probably find that the full filter behavior is generally what you want when filtering your data, it might be too strict in other situations. If other rules on the Rulesheet act or operate on `Policy`, then a maximum filter gives you a very easy way to specify and control *which* `Policy` entities are affected.

---

**Note:** Full filtering, or *maximum* filtering, is also the original behavior of Filters (and of their Precondition/Filter counterparts in prior releases of Corticon Studio), so for backward compatibility purposes with older models written with these expectations, we have kept it this way as new versions of Corticon have been released over the years. We wouldn't want to change an important behavior like this and have older Rule Sets begin acting completely differently from their authors' intentions.

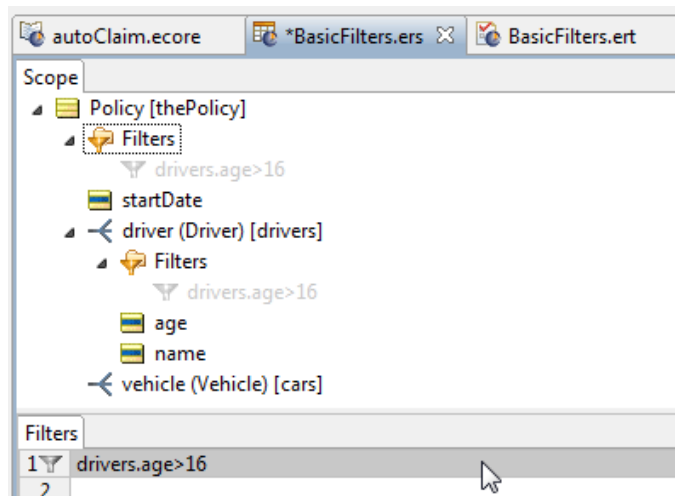

---

## Disabling a Full Filter

In testing you will find times when you might want to remove one filter. Instead of deleting the filter, you can simply *disable* it by right-clicking the rule and then choosing **Disable**, as shown:

Once disabled all applications of the filter are rendered in gray, as shown:

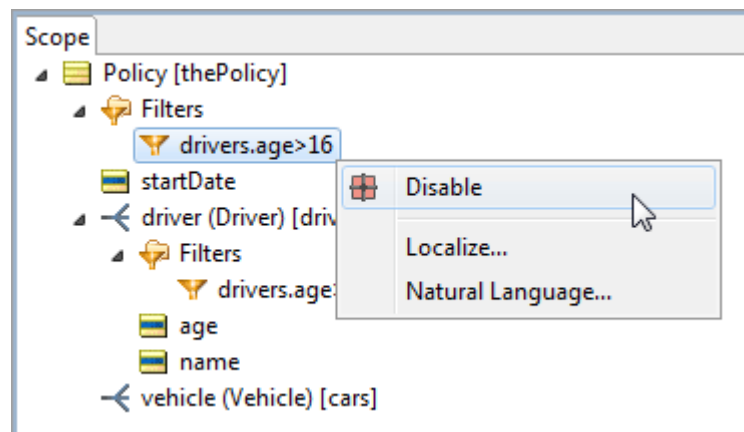

A disabled full filter is really no filter at all. You can perform the corresponding action to again **Enable** the filter.

## Limiting filters

There are occasions, however, when the all-or-nothing behavior of a full Filter is unwanted because it is too strong. In these cases, we want to apply a Filter to specified elements of a collection but still keep the selected entities even if none of the children survive the Filter.

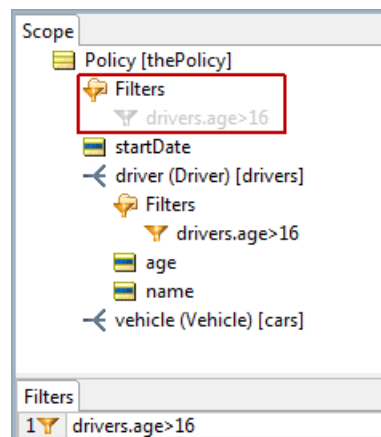

To turn a Filter expression into a limiting Filter, right-click on a Filter in the scope section and select **Disable** from the menu, as shown:

**Figure 145: Selecting to limit a filter**

This causes that specific filter position to no longer apply, indicated in gray:

**Figure 146:**

Notice that the filter is still enabled, and that it will still be applied at the `Driver` level. We have **limited** the filter.

### Use case for limiting filters

The preceding example was basic. Let's explore a some more complex example of limited filters. Consider the case where there is a rule component designed to process customers and orders. A Customer has a 1 to many relationship with an Order.

The rule component has 2 objectives, one to process customers and the second to process orders.

If we define a filter that tests for a GOLD status on an order we can have four logical iterations of how the filter could be applied to the ruleset.

- Case 1: filter is not applied at all.
- Case 2: filter is applied to all customers and all orders.
- Case 3: filter is only applied to customers.
- Case 4: filter is only applied to orders.

A business statement for these cases could be as follows:

```
Case 1: Process all customers and all orders.
Case 2: Process only GOLD status orders and only customers that have a GOLD
status order.
Case 3: Process only customers that have a GOLD status order and all orders
of a processed customer.
Case 4: Process all customers and only GOLD status orders.
```

For filter modeling, the filter expression could be written as `Customer.order.status = 'GOLD'`  
The modeling consideration for the cases are:

```
Case 1: Filter is not entered (or filter disabled, or filter disabled at
both Customer and Customer.order levels in the scope).
Case 2: Filter is entered with no scope modifications (enabled at both
Customer and Customer.order levels in the scope).
Case 3: Filter is entered and then disabled at the Customer.order level in
the scope.
Case 4: Filter is entered and then disabled at the Customer level in the
scope.
```

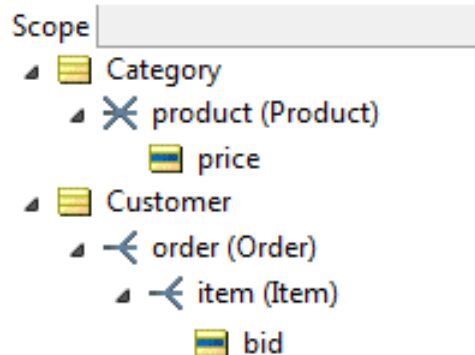

You see how one filter can apply limits to the full filter to achieve the preferred profile of what survives the filter and what gets filtered out.

Next, let's look at more complex set of limiting filters.

### Example of limiting filters

Consider the following Rulesheet Scope of a Vocabulary:

**Figure 147: Scope in a Rulesheet that will be filtered**

Consider the filter to be applied to data:

```
Customer.order.item.bid >= Category.product.price
```

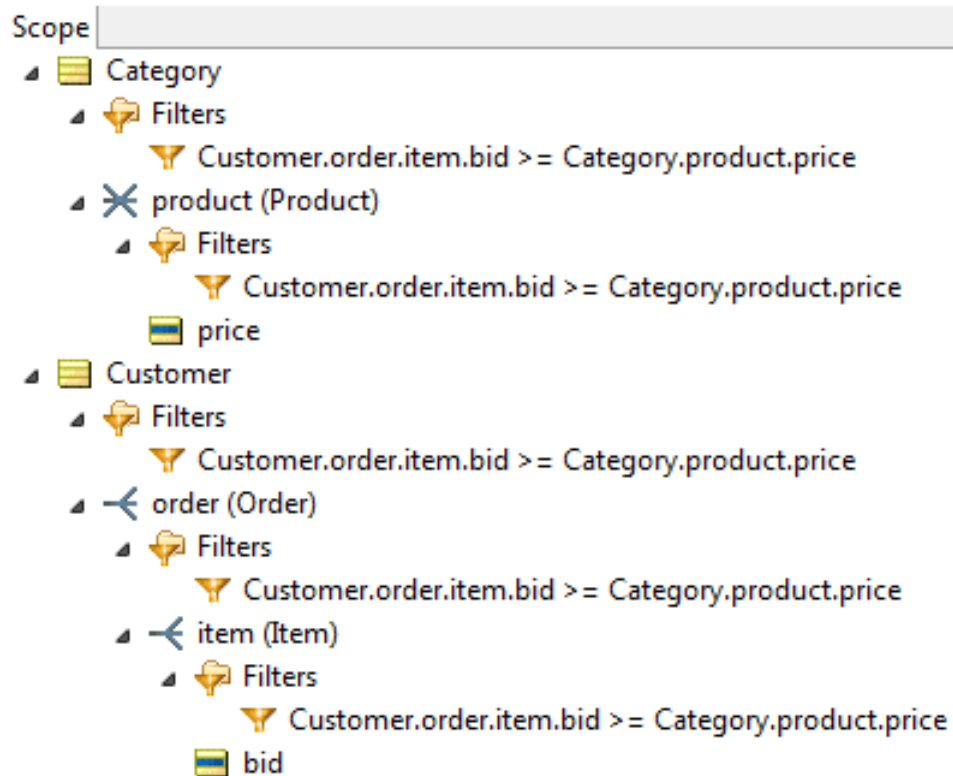

This is shown in the Rulesheet's **Filters** section as:

**Figure 148: Definition of a filter**

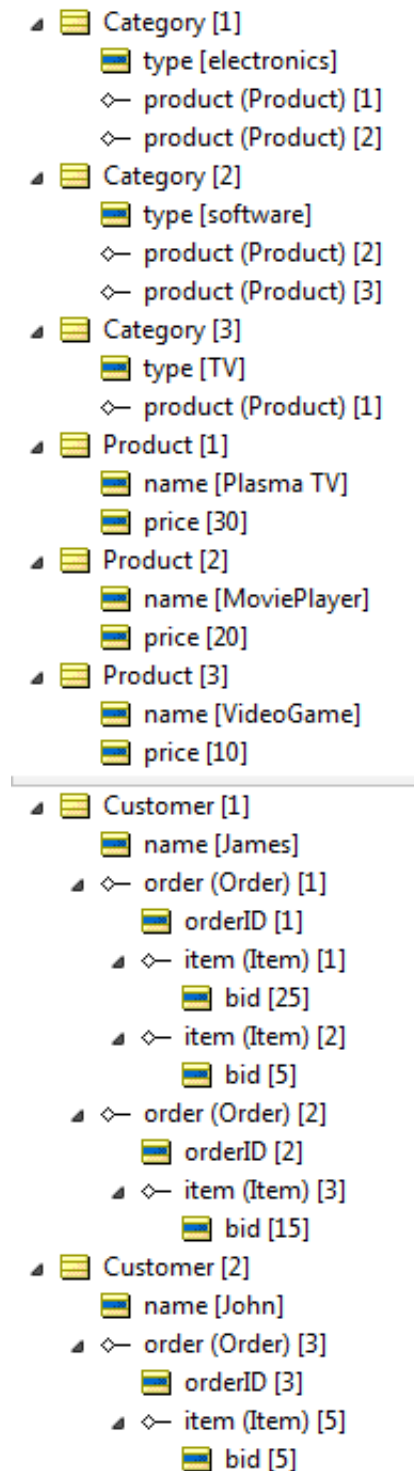

The resulting filter application applies at several levels, as shown:

**Figure 149: Application of the filter to the Scope's tree structure**

A Ruletest Testsheet might be created as follows:

**Figure 150:**

This data tree contains five entity types (Customer, Order, Item, Category, Product).

This filter is evaluated as follows:

```

Customer[1],Order[1],Item[1],Category[1],Product[1] false
Customer[1],Order[1],Item[1],Category[1],Product[2] true

```

```
Customer[1],Order[1],Item[1],Category[2],Product[2] true
Customer[1],Order[1],Item[1],Category[2],Product[3] true
Customer[1],Order[1],Item[1],Category[3],Product[1] false
Customer[1],Order[1],Item[2],Category[1],Product[1] false
Customer[1],Order[1],Item[2],Category[1],Product[2] false
Customer[1],Order[1],Item[2],Category[2],Product[2] false
Customer[1],Order[1],Item[2],Category[2],Product[3] false
Customer[1],Order[1],Item[2],Category[3],Product[1] false
Customer[1],Order[2],Item[3],Category[1],Product[1] false
Customer[1],Order[2],Item[3],Category[1],Product[2] false
Customer[1],Order[2],Item[3],Category[2],Product[2] false
Customer[1],Order[2],Item[3],Category[2],Product[3] true
Customer[1],Order[2],Item[3],Category[3],Product[1] false
Customer[2],Order[3],Item[5],Category[1],Product[1] false
Customer[2],Order[3],Item[5],Category[1],Product[2] false
Customer[2],Order[3],Item[5],Category[2],Product[2] false
Customer[2],Order[3],Item[5],Category[2],Product[3] false
Customer[2],Order[3],Item[5],Category[3],Product[1] false
```

The tuples that evaluate to true are:

```
Customer[1],Order[1],Item[1],Category[1],Product[2]
Customer[1],Order[1],Item[1],Category[2],Product[2]
Customer[1],Order[1],Item[1],Category[2],Product[3]
Customer[1],Order[2],Item[3],Category[2],Product[3]
```

The entities that survive the filter are:

```
Customer[1]
Customer[1],Order[1]
Customer[1],Order[2]
Customer[1],Order[1],Item[1]
Customer[1],Order[2],Item[3]
Category[1]
Category[2]
Category[1],Product[2]
Category[2],Product[2]
Category[2],Product[3]
```

The Scope section of the Rulesheet expands as follows:

Notice how the filter is applied towards each discrete entity referenced in the expression:

- When the filter is applied to `Customer`, then the survivor of the filter is `Customer[1]`, if not applied then `{Customer[1], Customer[2]}` survive the filter.
- When the filter is applied to `Customer.order` then the surviving tuples are `{Customer[1], Order[1]}` and `{Customer[1], Order[2]}`. When **not** applied then it is the same (because there was no `Order` child of `Customer[1]` that did not survive the filter).
- When the filter is **not** applied at the `Customer` level as well as the `Customer.order` level, then all `Customer.order` tuples survive the filter with result `{Customer[1],Order[1]}`, `{ Customer[1],Order[2]}`, `{Customer[2],Order[3]}`
- When the filter is applied to `Customer.order.item` then the surviving tuples are `{Customer[1],Order[1],Item[1]}` and `{Customer[1],Order[2],Item[3]}`. When **not** applied (at this level but at higher levels) then the surviving tuples will be `{Customer[1],Order[1],Item[1]}`, `{Customer[1],Order[1],Item[2]}`, `{Customer[1],Order[2],Item[3]}`
- When the filter is applied to `Category` then the surviving entities are `Category[1]`, `Category[2]`. When **not** applied then `Category[1]`, `Category[2]`, `Category[3]`.

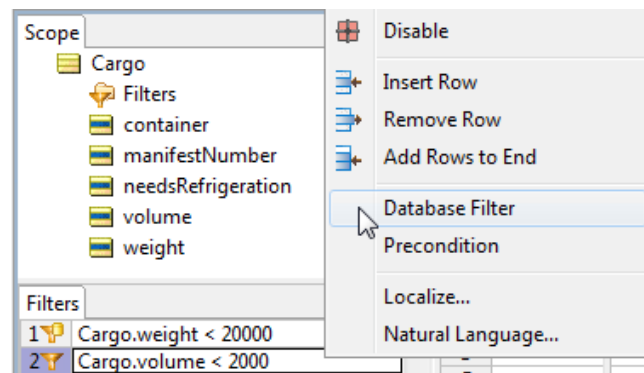

- When the filter is applied to the `Category.product` level then the surviving tuples will be `{Category[1], Product[2]}`, `{Category[2], Product[2]}`, `{Category[2], Product[3]}`

You see how a filter applied (at each level) determines which entities are processed when a rule references a subset of the filter's entities. With the *limiting filters* feature, the filter may or may not be applied to each entity referenced by the filter.

## Database filters

When set to Integration and Deployment mode, a filter provides a toggle for **Database Filter**, as shown:

**Figure 151: Setting a database filter**

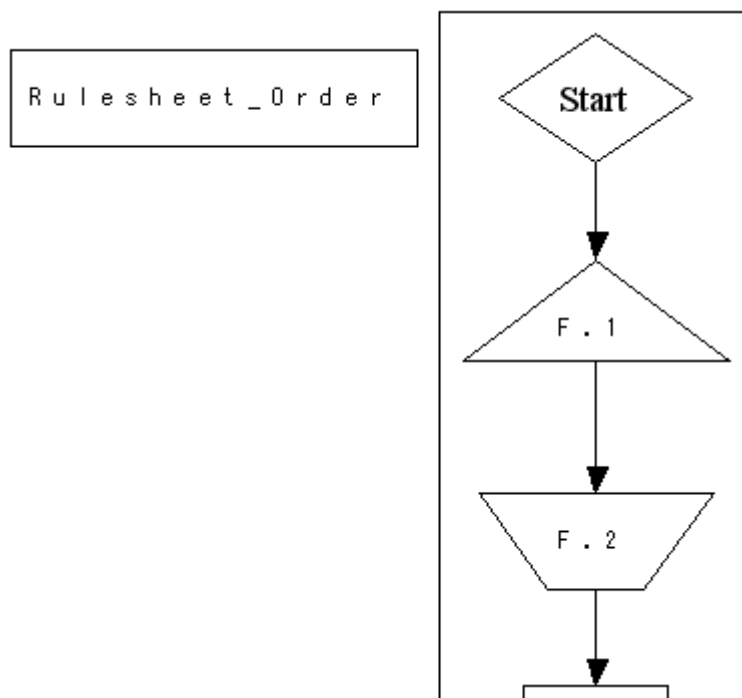

When the option is cleared, the filter is applied only to data currently in working memory.

When checked, the filter becomes a *database query* that will retrieve data from the database, and then add the retrieved data to working memory.

A database filter is distinguished by a database cylinder decoration as shown, where filter 1 is a database filter and filter 2 is a local filter:

When you choose **Rulesheet > Logical Analysis > Execution Sequence Diagram**, the graphic that is generated distinguishes a database filter from local filter by its shape:

In this example, **F.1**, the database query, is displayed within a triangle while **F.2**, the local filter, is displayed within an inverted trapezoid (a quadrilateral with parallel horizontal bases and legs that converge downward.)

## What is a precondition?

If you're comfortable with the limiting and full behaviors of a Filter expression, then its precondition behavior is even easier to understand. While reading this section, keep in mind that *Filters always act as either limiting or full filters, but they can **also** act as preconditions* if you enable that behavior as described in this section. If you think of filtering as a *mandatory* behavior but a precondition as an extra, *optional* behavior, then you will be in good shape later. Also, it may be helpful to think of the precondition behavior, if enabled, taking effect *after* the filtering step is complete.

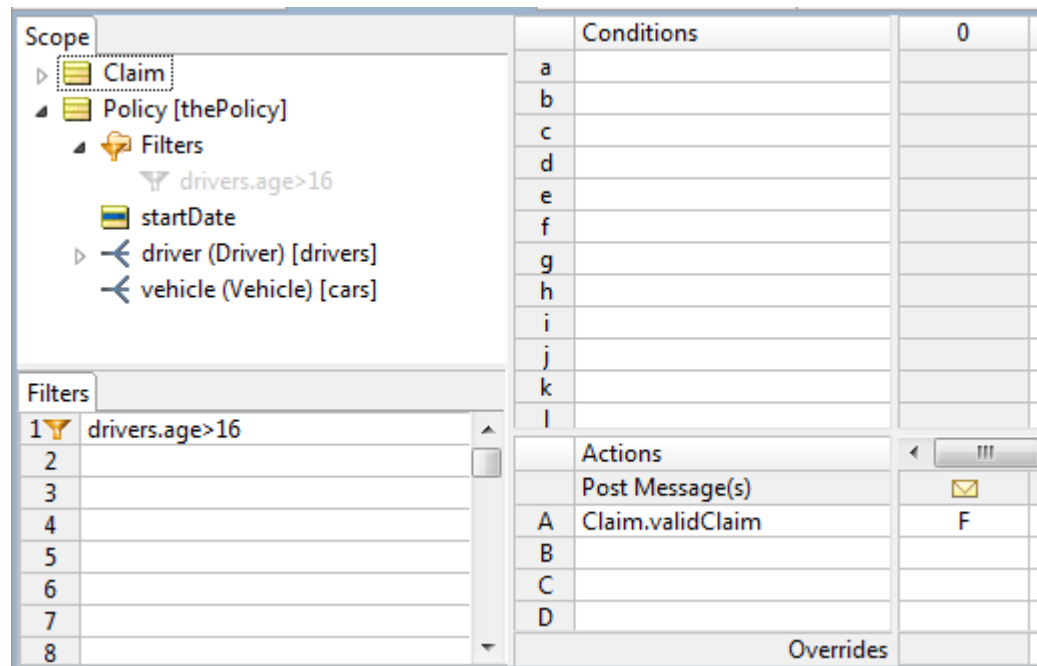

Precondition behavior of a Filter ensures that execution of a Rulesheet **stops** unless *at least one* piece of data survives the Filter. If execution of a Rulesheet stops because no data survived the Filter, then execution moves on to the next Rulesheet (in the case where the Rulesheet is part of a Ruleflow). If no more Rulesheets exist in the Ruleflow, then execution of the entire Ruleflow is complete.

In effect, a Filter with precondition behavior enabled acts as a "gatekeeper" for the entire Rulesheet - if no data survived the Filter, then the Rulesheet's "gate stays closed" and no additional rules on that Rulesheet will be evaluated or executed *no matter what*.

If however, data survived the Filter, then the "gate opens" and the surviving data can be used in the evaluation and execution of other rules on the same Rulesheet.

The precondition behavior of a Filter is significant because it allows us to control Rulesheet execution regardless of the scope used in the rules. Take for example the Rulesheet shown in the following figure. The Filter in row 1 is acting in its standard default mode of full filter. This means that `Driver` entities in the collection named `drivers` and the collection's parent entity `Policy` are both affected by this Filter. Only those elements of `drivers` older than 16 will survive, and at least one must survive for the parent `Policy` also to survive.

**Figure 152: Input Rulesheet for Precondition**

But how does this affect the `Claim` in Nonconditional row A (of rule column 0)? `Claim`, as a root-level entity, is safely *outside of the scope* of our Filter, and therefore unaffected by it. Nothing the Filter does (or doesn't do) has any effect on what happens in Action row A – the two logical expressions are completely independent and unrelated. As a result, `Claim.validClaim` will always be `false`, even when none of the elements in `drivers` are older than 16. A quick Ruletest verifies this prediction:

**Figure 153: Rulesheet for an Action Unaffected by a Filter**

Input	Output
<ul style="list-style-type: none"> <li>Policy [1] <ul style="list-style-type: none"> <li>driver (Driver) [1] <ul style="list-style-type: none"> <li>age [13]</li> <li>name [Jacob]</li> </ul> </li> <li>driver (Driver) [2] <ul style="list-style-type: none"> <li>age [14]</li> <li>name [John]</li> </ul> </li> <li>driver (Driver) [3] <ul style="list-style-type: none"> <li>age [10]</li> <li>name [Lisa]</li> </ul> </li> </ul> </li> <li>Claim [1] <ul style="list-style-type: none"> <li>validClaim</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>Policy [1] <ul style="list-style-type: none"> <li>driver (Driver) [1] <ul style="list-style-type: none"> <li>age [13]</li> <li>name [Jacob]</li> </ul> </li> <li>driver (Driver) [2] <ul style="list-style-type: none"> <li>age [14]</li> <li>name [John]</li> </ul> </li> <li>driver (Driver) [3] <ul style="list-style-type: none"> <li>age [10]</li> <li>name [Lisa]</li> </ul> </li> </ul> </li> <li>Claim [1] <ul style="list-style-type: none"> <li>validClaim [false]</li> </ul> </li> </ul>

But what if the business intent of our rule is to update `Claim` based on the evaluation of `Policy` and its collection of `Drivers`? What if the business intent *requires* that the `Policy` and `Claim` really be related in some way? How do we model this?

Before "true" precondition behavior was introduced in Studio 4.0, our only practical option was to mandate an actual physical association between `Policy` and `Claim`, then incorporate that association into the scope of our Filter and rules. For example:

Figure 154: Rulesheet for Precondition

Scope		Conditions	0
Claim		a	
Policy [thePolicy]		b	
Filters		c	
drivers.age>16		d	
startDate		e	
driver (Driver) [drivers]		f	
vehicle (Vehicle) [cars]		g	
		h	
		i	
		j	
		k	
		l	
Filters		Actions	
1	drivers.age>16	Post Message(s)	
2		A Claim.validClaim	F
3		B	
4		C	
5		D	
6		Overrides	
7			
8			

Notice that `Claim` is no longer a root-level entity – we have associated it with `Policy` and given the *associated* `Claim` an alias `aClaim`. It is the alias, not the root-level entity, that's used in Nonconditional row A. So, when no elements of `drivers` are older than 16, the full filter ensures the parent `Policy` entity does not survive. And since the `Policy` does not survive the filter, its associated `Claim` does not survive, either. Here's an example of this:

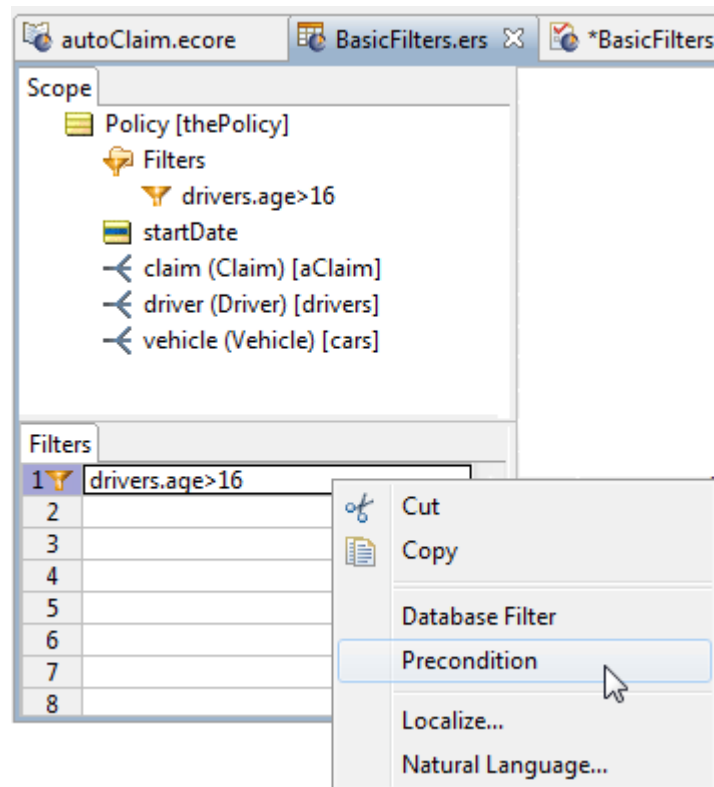

Figure 155: Ruletest for Precondition

Input	Output
Policy [1]	Policy [1]
driver (Driver) [1]	driver (Driver) [1]
age [13]	age [13]
name [Jacob]	name [Jacob]
driver (Driver) [2]	driver (Driver) [2]
age [14]	age [14]
name [John]	name [John]
driver (Driver) [3]	driver (Driver) [3]
age [10]	age [10]
name [Lisa]	name [Lisa]
Claim [1]	Claim [1]
validClaim	validClaim [false]

The net effect is that `validClaim` can only be `false` when one or more drivers is older than 16, which is what we want. But obtaining this result required us to "monkey around" with our data -- and, possibly our Vocabulary, data model, and database schema as well -- to associate `Claim` with `Policy`. Sometimes we as rule modelers have this freedom and flexibility. Often, we do not. If we don't, then we need an alternative method for controlling the execution of subsequent rules without relying on "unnatural" or artificial data and/or data model manipulations. Here's where the precondition behavior is useful.

Using the same example as in above, right-click on Filter row 1 and select **Precondition**.

**Figure 156: Selecting Precondition Behavior from the Filter Right-Click Popup Menu**

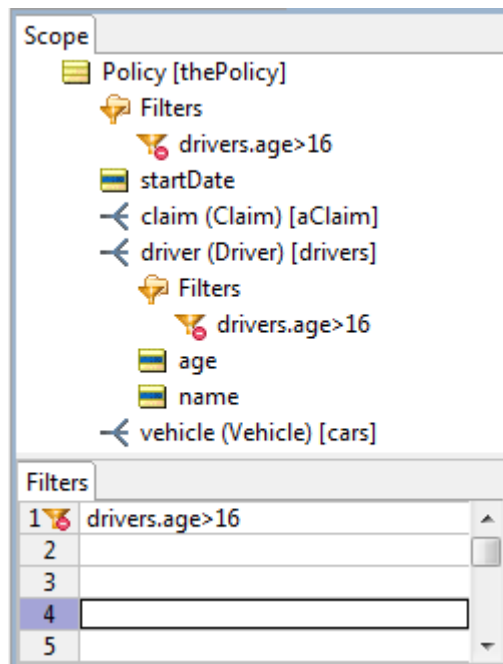

Note that the two options **Precondition** and **Limiting Filter** are mutually exclusive: turning one on turns the other off. A Filter cannot be both a Precondition AND a limiting Filter because at least one piece of data ALWAYS survives a limiting filter, so a Precondition would never stop execution.

Selecting **Precondition** causes the following:

- The yellow funnel icon in the **Filter** window receives a small red circle symbol
- The yellow funnel icons in the **Scope** window receive small red circle symbols

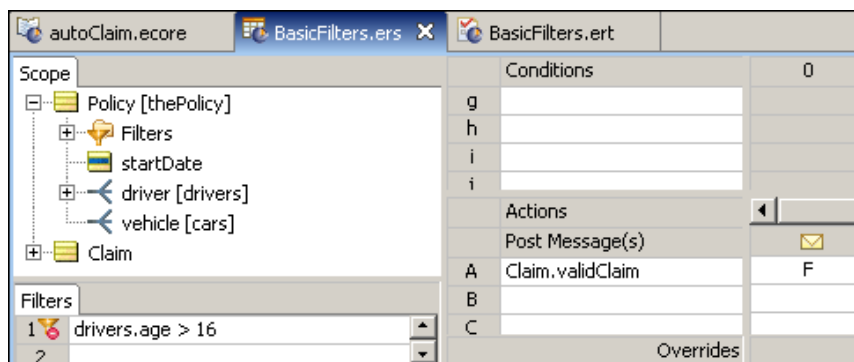

The following figure shows a Filter in **Precondition** mode.

**Figure 157: A Filter in Precondition Mode**

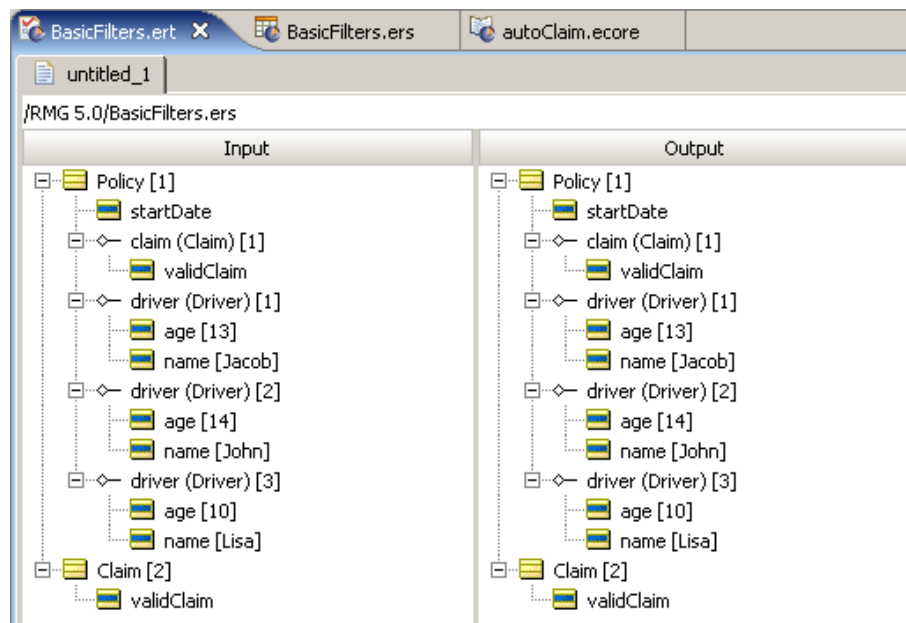

As described before, the precondition behavior of the Filter will cause Rulesheet execution to stop whenever no data survives the Filter. So in the original case where `Policy` and `Claim` were unassociated, a Filter in precondition mode, as shown:

**Figure 158: Rulesheet with a Filter in Precondition Mode**

accomplishes our business intent without artificially changing our Vocabulary or underlying data model. A final proof is provided in the following figure:

**Figure 159: Testsheet for a Filter in Precondition Mode**

## Summary of filter and preconditions behaviors

- A Filter just reduces the available data for other rules in the Rulesheet to use. Filters produce shades of gray - all data, some data, or no data may result from a filter.
- A Filter in **Precondition** mode stops Rulesheet execution if no data survives the filter. Preconditions produce black and white results: either data survives the filter and the precondition allows Rulesheet execution to continue, or no data survives and the precondition forces Rulesheet execution to stop.
- Filter expressions always acts as a filter. By default, they act as filters *only*. If you also need true precondition behavior, then setting the Filter to **Precondition** mode will enable precondition behavior while keeping filter behavior.

## Performance implications of the precondition behavior

A rule fires whenever data sharing the rule's scope exists that satisfies the rule's conditions. In other words, to fire any rule, the rule engine must first collect the data that shares the rule's scope, and then check if any of it satisfies the rule's conditions. So even in a Rulesheet where no rules actually fire, the rule engine may have still needed to work hard to come to that conclusion. And hard work requires time, even for a high-performance rule engine like Corticon has.

A Filter expression acting only as a filter never stops Rulesheet execution; it simply limits the amount of data used in rule evaluations and firings. In other words, it *reduces the set of data that is evaluated* by the rule engine, but it does not actually stop the rule engine's *evaluation* of remaining rules. Even if a filter successfully filters out all data from a given data set, the rule engine will still evaluate this empty set of data against the available remaining rules. Of course, no rules will fire, but the evaluation process still occurs and still takes time.

Filter expressions also acting as preconditions change this. Now, if no data survives the filter (remember, Filter expressions always act as filters even when also acting as preconditions) then Rulesheet execution stops in its tracks. No additional evaluations are performed by the rule engine. That Rulesheet is done and the rule engine begins working on the next Rulesheet. This can save time and improve engine performance when the Rulesheet contains many additional rules that would have been at least evaluated were the expression in filter-only mode (the default mode).

## Using collection operators in a filter

In the following examples, all Filter expressions use their default Filter-only behavior. As we discussed in the [Rule Writing Techniques](#) chapter, the logic expressed by the following three Rulesheets provides the same result:

**Figure 160: A Condition/Action rule column with 2 Conditional rows**

The screenshot shows a Rulesheet editor window titled "CollectionOperatorsInAFilter.ers". The interface is divided into several sections:

- Scope:** A tree view showing a folder "Person [p]".
- Conditions:** A table with columns "Conditions", "0", and "1".
 

Conditions	0	1
a p.skydiver		T
b p.age > 40		T
c		
- Filters:** A table with columns "Filters", "A", "B", and "Overrides".
 

Filters	A	B	Overrides
1			
2			
3			
4			
- Actions:** A table with columns "Post Message(s)", "A", "B", and "Overrides".
 

Post Message(s)	A	B	Overrides
1			
2			
3			
4			
- Rule Statements:** A table with columns "Ref", "ID", "Post", "Alias", and "Text".
 

Ref	ID	Post	Alias	Text
1				A person over 40 who skydives is high risk

**Figure 161: Rulesheet with one Condition row moved to Filters row**

The screenshot shows a Rulesheet editor window titled "ConditionalMovedToPrecondition.ers". The interface is similar to Figure 160, but with one change:

- Conditions:** The table now only has one row:
 

Conditions	0	1
a p.age > 40		T
b		
c		
- Filters:** The table now has one row:
 

Filters	A	B	Overrides
1 p.skydiver = T			
2			
3			
4			

**Figure 162: Rulesheet with Filter and Condition rows swapped**

The screenshot shows a Rulesheet editor window titled "ConditionAndPreconditionSwapped.ers". The interface is similar to Figure 161, but with one change:

- Conditions:** The table now has one row:
 

Conditions	0	1
a p.skydiver		T
b		
c		
- Filters:** The table now has one row:
 

Filters	A	B	Overrides
1 p.age > 40			
2			
3			
4			

Even though expressions in the Filters section of the Rulesheet are evaluated before Conditions, the results are the same. This holds true for all rule expressions that do not involve collection operations (and therefore do not need to use aliases – we have used aliases in this example purely for convenience and brevity of expression): conditional statements, whether they are located in the Filters or Conditions sections, are **AND**'ed together. Order does not matter.

In other words, to use the logic from the preceding example:

```
If person.age > 40 AND person.skydiver = true, then person.riskRating = 'high'
```

Because it does not matter which conditional statement is executed first, we could have written the same logic as:

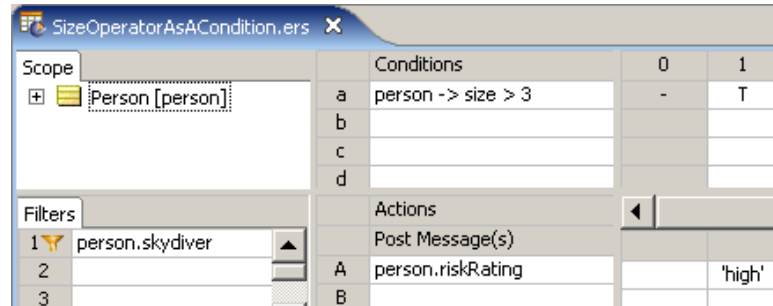

```
If person.skydiver = true AND person.age > 40, then person.riskRating = 'high'
```

This independence of order is similar to the commutative property of multiplication:  $4 \times 5 = 20$  and  $5 \times 4 = 20$ . Aliases work perfectly well in a declarative language (like Corticon's) because regardless of the order of processing, the outcome is always the same.

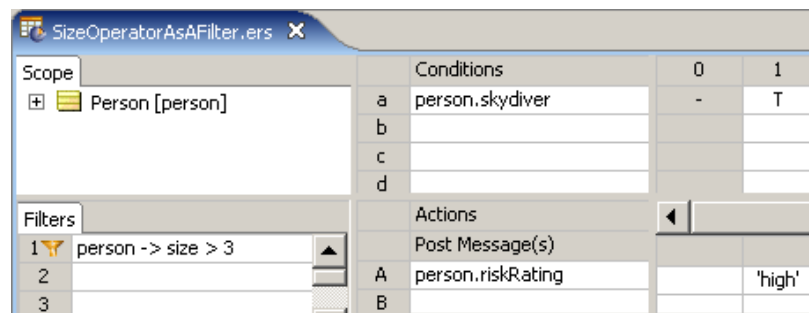

## Location matters

Unfortunately, order independence does **not** apply to conditional expressions that include collection operations. In the following Rulesheets, notice that one of the conditional expressions uses the collection operator `->size`, and therefore must use an alias to represent the collection `Person`.

**Figure 163: Collection Operator in Condition row**

**Figure 164: Collection Operator in Filter row**

The Rulesheets appear identical with the exception of the location of the two conditional statements. But do they produce identical results? Let's test the Rulesheets to see, testing **Collection Operator in Condition row** first:

**Figure 165: Ruletest with 3 Skydivers**

Input	Output
Person [1] skydiver [true]	Person [1] skydiver [true]
Person [2] skydiver [true]	Person [2] skydiver [true]
Person [3] skydiver [false]	Person [3] skydiver [false]
Person [4] skydiver [true]	Person [4] skydiver [true]

What happened here? Because Filters are always applied first, our Rulesheet initially "screened" or "filtered out" the elements of collection `person` whose `skydiver` value was `false`. Think of the Filter as allowing only skydivers to "pass through" to the rest of the Rulesheet. The Conditional rule then checks to see if the number of elements in collection `person` is more than 3. If it is, then ALL `person` elements in the collection *that pass through the filter* (in other words, all skydivers) receive a `riskRating` value of 'high'. Because our first Ruletest included only 3 skydivers, the collection fails the Conditional rule, and no value is assigned to `riskRating` for any of the elements, skydiver or not.

Let's modify the Ruletest and rerun the rules:

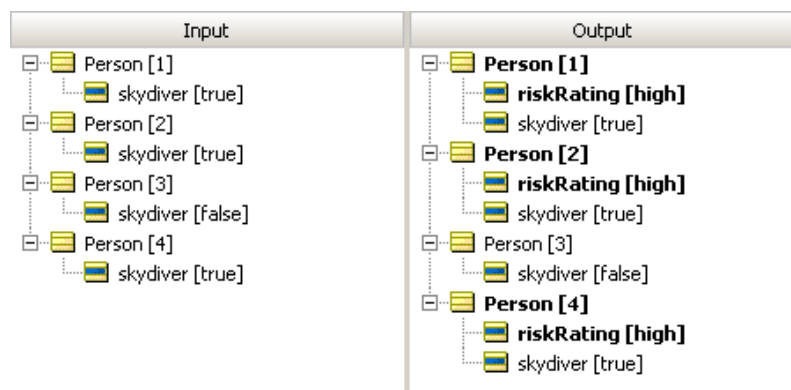

**Figure 166: Ruletest with 4 Skydivers**

Input	Output
Person [1] skydiver [true]	Person [1] riskRating [high] skydiver [true]
Person [2] skydiver [true]	Person [2] riskRating [high] skydiver [true]
Person [3] skydiver [false]	Person [3] skydiver [false]
Person [4] skydiver [true]	Person [4] riskRating [high] skydiver [true]
Person [5] skydiver [true]	Person [5] riskRating [high] skydiver [true]

It's clear from this run that our rules fired correctly, and assigned a `riskRating` of 'high' to all skydivers for a collection containing more than 3 skydivers.

Now let's test the Rulesheet in [Collection Operator in Filter row](#), where the rule containing the collection operation is in the Filters section.

**Figure 167: Ruletest with 3 Skydivers**

What happened this time? Because Filters apply first, the `->size` operator counted the number of elements in our `person` collection, regardless of who skydives and who does not. Here, the Filter allows any collection – *and the whole collection* – of more than 3 persons to "pass through" to the Conditions section of the Rulesheet. Then, the Conditional rule checks to see if any of the elements in collection `person` skydive. Each `person` who skydives receives a `riskRating` value of `high`. Even though our Ruletest included only 3 skydivers, the collection contains 4 persons and therefore passes the Preconditional filter. Any `skydiver` in the collection then has its `riskRating` assigned a value of `high`.

It's important to point out that the Rulesheets in [Collection Operator in Condition row](#) and [Collection Operator in Filter row](#) really implement two different business rules. When we built our Rulesheets, we neglected to write the plain-language business rule statements (violating our methodology!). The rule statements for these two Rulesheets would look like this:

1. All skydivers in groups of more than 3 **skydivers** must be assigned a `riskRating` of 'high'
2. All skydivers in groups of more than 3 **persons** must be assigned a `riskRating` of 'high'

The difference here is subtle but important. In the first rule statement, we are testing for skydivers within groups that contain more than 3 *skydivers*. In the second, we are testing for skydivers within groups of more than 3 *people*.

## Multiple filters on collections

Let's construct a slightly more complicated example by adding a third conditional expression to our rule.

**Figure 168: Rulesheet with 2 Conditions**

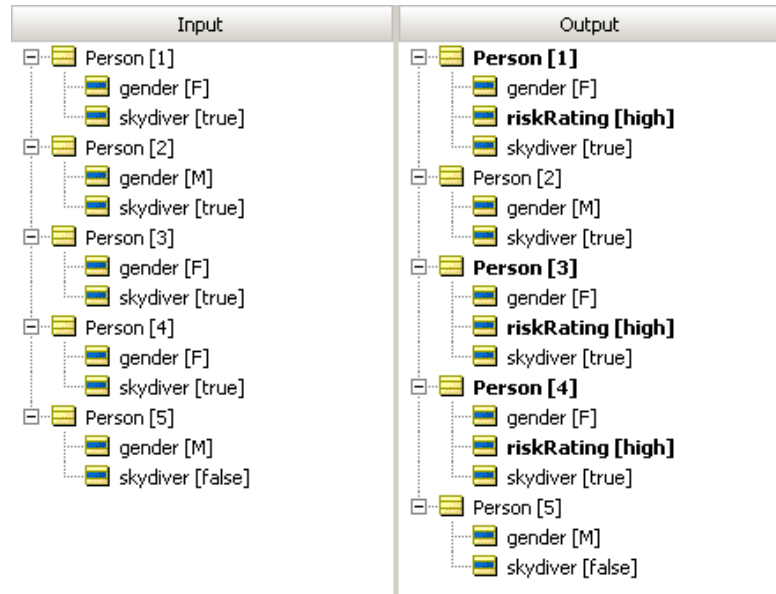

Scope		Conditions	0	1
+	Person [person]	a	person -> size > 3	T
		b	person.gender = 'F'	T
		c		
		.		
Filters		Actions		
1	person.skydiver = true	Post Message(s)		
2		A	person.riskRating	'high'
3		-	Overrides	

**Figure 169: Rulesheet with 2 Filters**

Scope		Conditions	0	1
+	Person [person]	a	person -> size > 3	T
		b		
		c		
		.		
Filters		Actions		
1	person.skydiver = true	Post Message(s)		
2	person.gender = 'F'	A	person.riskRating	'high'
3		-	Overrides	

Once again, our Rulesheets differ only in the location of a Conditional expression. In the first rulesheet above, the gender test is modeled in the second Conditional row, whereas in the other rulesheet (Rulesheet with 2 Filters), it's implemented in the second Filter row. Does this difference have an impact on rule execution? Let's build a Ruletest and use it to test the Rulesheet in **Rulesheet with 2 Conditions** first.

**Figure 170: Ruletest**

As we see in this figure, the combination of a Condition that uses a collection operator (the size test) with another Condition that does not (the gender test) produces an interesting result. What appears to have happened is that, for a collection of more than 3 skydivers, all females in that group have been assigned a `riskRating` of 'high'. Step-by-step, here is what the Corticon Server did:

1. The Filter screened the collection of Persons (represented by the alias `person`) for skydivers.
2. If there are more than 3 "surviving" elements in `person` (i.e., skydivers), then all females in the filtered collection are assigned a `riskRating` value of `high`. It may be helpful to think of the Corticon Server checking to make sure there are more than three surviving elements, then "cycling through" those whose gender is female, and assigning `riskRating` one element at a time.

Expressed as a plain-language rule statement, our Rulesheet implements the following rule statement:

1. All female skydivers in a group of more than 3 skydivers must be assigned a `riskRating` value of `high`

It's important to note that Conditions **do not** have the same filtering effect on collections that Filter expressions do, and the order of Conditions in a rule has *no effect whatsoever* on rule execution.

Now that we understand the results in [Ruletest](#), let's see what our second Rulesheet produces.

**Figure 171: Ruletest**

Input	Output
<div>Person [1]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [1]</div> <div>gender [F]</div> <div>skydiver [true]</div>
<div>Person [2]</div> <div>gender [M]</div> <div>skydiver [true]</div>	<div>Person [2]</div> <div>gender [M]</div> <div>skydiver [true]</div>
<div>Person [3]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [3]</div> <div>gender [F]</div> <div>skydiver [true]</div>
<div>Person [4]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [4]</div> <div>gender [F]</div> <div>skydiver [true]</div>
<div>Person [5]</div> <div>gender [M]</div> <div>skydiver [false]</div>	<div>Person [5]</div> <div>gender [M]</div> <div>skydiver [false]</div>

This time, no `riskRating` assignments were made to any element of collection `person`. Why? Because multiple Filters are logically **AND**'ed together, forming a compound filter. In order to survive the compound filter, elements of collection `person` must be both skydivers **AND** female. Elements that survive this compound filter pass through to the "size test" in the Condition/Action rule, where they are counted. If there are more than 3 remaining, then all surviving elements are assigned a `riskRating` value of `high`. Rephrased, our Rulesheet implements the following rule statement:

1. All female skydivers in a group of more than 3 female skydivers must be assigned a `riskRating` of `high`

Just to confirm we understand how the Corticon Server is executing this Rulesheet, let's modify our Ruletest and rerun:

**Figure 172: Ruletest**

Input	Output
<div>Person [1]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [1]</div> <div>gender [F]</div> <div><b>riskRating [high]</b></div> <div>skydiver [true]</div>
<div>Person [2]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [2]</div> <div>gender [F]</div> <div><b>riskRating [high]</b></div> <div>skydiver [true]</div>
<div>Person [3]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [3]</div> <div>gender [F]</div> <div><b>riskRating [high]</b></div> <div>skydiver [true]</div>
<div>Person [4]</div> <div>gender [F]</div> <div>skydiver [true]</div>	<div>Person [4]</div> <div>gender [F]</div> <div><b>riskRating [high]</b></div> <div>skydiver [true]</div>
<div>Person [5]</div> <div>gender [M]</div> <div>skydiver [false]</div>	<div>Person [5]</div> <div>gender [M]</div> <div>skydiver [false]</div>

[Ruletest](#) now includes 4 female skydivers, so, if we understand our rules correctly, we expect all 4 to pass through the compound filter and then satisfy the size test in the Conditions. This should result in all 4 surviving elements receiving a `riskRating` of `high`. [Ruletest](#) confirms our understanding is correct.

## Filters that use OR

Just as compound filters can be created by writing multiple Preconditions, filters can also be constructed using the special word `or` directly in the Rulesheet. See the *Rule Language Guide* for an example.

## Test yourself - questions – filters & preconditions

---

**Note:** Try this test, and then go to **Answers:** [Preconditions & filters](#) on page 287 to correct yourself.

---

1. True or False. All expressions modeled in the Filters section of the Rulesheet behave as filters.
2. True or False. All expressions modeled in the Filters section of the Rulesheet behave as preconditions.
3. True or False. Some rules may be unaffected by Filters expressions on the same Rulesheet.
4. When 2 conditional expressions are expressed as 2 Filter rows, they are logically \_\_\_\_\_ together.

or'ed	and'ed	replaced	duplicated
-------	--------	----------	------------

5. True or False. A Filter row is a stand-alone rule that can be assigned its own Rule Statement
6. A null collection is a collection that:
  - a. has a parent but no children
  - b. has children but no parent
  - c. has no parent and no children
  - d. has a parent and children
7. An empty collection is a collection that:
  - a. has a parent but no children
  - b. has children but no parent
  - c. has no parent and no children
  - d. has a parent and children

8. A Filter expression is equivalent to a Conditional expression as long as it includes \_\_\_\_\_ collection operators in the expression.

some	all	no	at least one
------	-----	----	--------------

9. True or False. To join two Filters with an or operator, you must use the word or in between expressions.

10. By default, all Filter expressions are \_\_\_\_\_ filters

limiting	coffee	full	extreme
----------	--------	------	---------

11. The Filter expression shown below has which behavior(s)?

Filters	
1	 cars.make = 'Ford'
2	

limiting filter	full filter	precondition	noncondition
-----------------	-------------	--------------	--------------

12. The Filter expression shown below has which behavior(s)?

Filters	
1	 cars.make = 'Ford'
2	

limiting filter	full filter	precondition	noncondition
-----------------	-------------	--------------	--------------

13. What happens when a Filter expression, acting as a precondition, is not satisfied?

- The expression is ignored and Rulesheet execution continues
- The Rulesheet is re-executed from the beginning
- The last Rulesheet is executed
- The next Rulesheet is executed
- All Rulesheet execution stops
- Execution of that Rulesheet stops

14. Which Filters behaviors may be active at the same time?

- Full filter and precondition
- Limiting filter and precondition
- Limiting and full filter
- Precondition may only act alone

15. For the sample data shown below, determine which data survives the Filter for each question. Enter the entity number (the number in square brackets) for each survivor in the appropriate column. Assume the collection `Movie` has alias `movies`, `Movie.dvd` has alias `dvds`, and `Movie.oscar` has alias `oscars`. Full filters are shown in regular type and limiting filters are shown in **bold type**. None behave as Preconditions.

untitled_1	Precondition/Filter Expressions	Movie	DVD	Oscar
	<i>example:</i> movies.studio = 'RKO'	1	1	1,2,3,4,5
	a. dvd.priceTier = 'high'			
	b. oscars -> size > 4			
	c. oscars.win = T			
	d. oscars.nomination			
	e. oscars.win or oscars.category = 'Best Actor'			
	f. oscars.win and oscars.category = 'Best Actor'			
	g. dvd.quantityAvailable > 100			
	h. oscars -> exists(win = T)			
	i. movies.yearReleased.yearsBetween(today) > 50			
	j. dvd -> notEmpty			
	k. movies -> isEmpty			
	l. dvd.releaseDate > '1/1/2000'			
	m. movies.genre <> 'Drama'			
	n. oscars -> forAll(win = T)			
	o. oscars -> size > 2			

---

## Recognizing and modeling parameterized rules

---

For details, see the following topics:

- [Parameterized rule where a specific attribute is a variable \(or parameter\) within a general business rule](#)
- [Parameterized rule where a specific business rule is a parameter within a generic business rule](#)
- [Populating an AccountRestriction table from a sample user interface](#)
- [Test yourself - questions – recognizing and modeling parameterized rules](#)

### Parameterized rule where a specific attribute is a variable (or parameter) within a general business rule

During development, **patterns** may emerge in the way business rules define relationships between Vocabulary terms. For example, in our sample FlightPlan application, a recurring pattern might be that all aircraft have limits placed on their maximum takeoff weights. We might notice this pattern by examining specific business rules captured during the business analysis phase:

1. 747 aircraft must not exceed maximum cargo weight of 200,000 lbs
2. DC-10 aircraft must not exceed maximum cargo weight of 150,000 lbs

These rules are almost identical; only a few key parts – *parameters* – are different. Although aircraft type (747 or DC-10) and max cargo weight (200,000 or 150,000 lbs) are different in each rule, the basic form of the rule is the same. In fact, we can generalize the rule as follows:

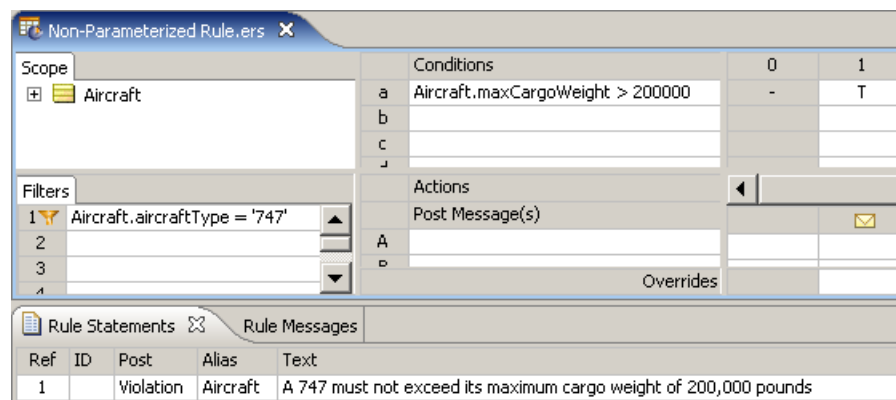

3. **X** aircraft must not exceed maximum cargo weight of **Y** lbs

Where the parameters **X** and **Y** can be organized in table form as shown below:

Aircraft type X	Maximum cargo weight Y
747	200,000
DC-10	150,000

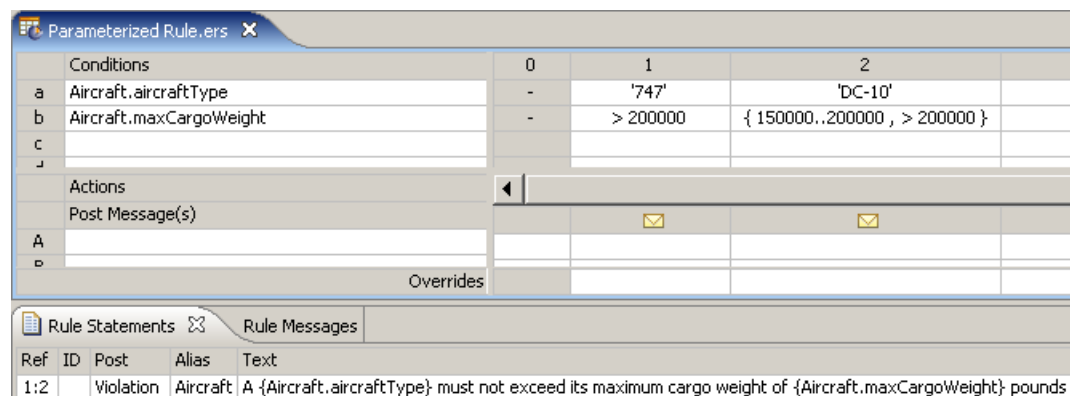

It is important to recognize these patterns because they can drastically simplify rule writing and maintenance in Corticon Studio. As shown in the following figure, we could build these two rules as a pair of Rulesheets, each with a Filter expression that filters data by `aircrafttype`.

**Figure 173: Non-Parameterized Rule**

But there is a simpler and more efficient way of writing these two rules that leverages the concept of parameterization. The following figure illustrates how this is accomplished:

**Figure 174: Parameterized Rules**

Notice how both rules are modeled on the same Rulesheet. This makes it easier to organize rules that share a common pattern and maintain them over time. If the air cargo company decides to add new aircraft types to its fleet in the future, the new aircraft types can simply be added as additional columns.

Also notice the business rule statements in the Rule Statements section. By entering 1:2 in the **Ref** column and inserting attribute names into the rule statement, the same statement can be reused for both rule columns. The syntax for inserting Vocabulary terms into a rule statement requires the use of { . . } curly brackets enclosing the term. See the *Rule Language Guide* for more details on embedding dynamic values in Rule Statements.

In addition to collecting parameterized rules on the same Rulesheet, other things can be done to improve rule serviceability. In the **Trade Allocation** sample application that accompanies the Corticon Studio installation, two parameterized rules are accessible directly from the application's user interface – the user can update these parameters without entering the Corticon Studio because they are stored externally. When the application runs, Corticon Studio accesses the parameter table to determine which rules should fire.

## Parameterized rule where a specific business rule is a parameter within a generic business rule

The previous section illustrated the simplest examples of parameterized rules. Other subtler examples occur frequently. For example, let's return to the **Trade Allocation** sample application included in the Corticon Studio installation.

A recurring pattern in **Trade Allocation** might be that specific accounts prohibit or restrict the holding of specific securities for specific reasons. We might notice this pattern by examining specific business rules captured during the business analysis phase:

1. The Airbus Account must not hold securities issued by its competitors.
2. The Puritan Pensions Account must not hold securities issued by companies in the Tobacco industry.
3. The SafeHaven Investments Account must not hold securities of less than investment grade quality (less than Bbb)

The first specific rule might be motivated by another, general rule that states:

4. A client's account must not invest in its competition

The general rule explains why Airbus places this specific restriction on its account holdings – Boeing is a competitor. The second rule is very similar in that it also defines an account restriction for a security attribute (the issuer's industry classification), even though the rule has a different motivation. (A client's investments must not conflict with its ethical guidelines?)

There may be many other business rules that share a common structure, meaning similar entity context and scope. This pattern allows us to define a generic business rule:

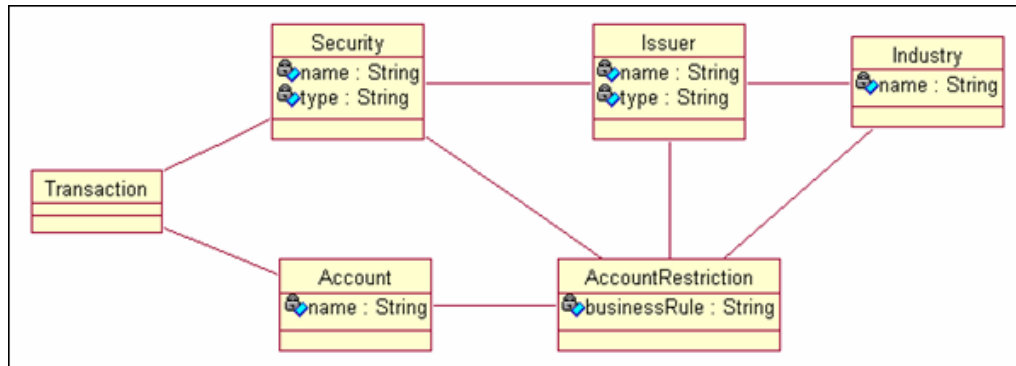

5. An **Account** may restrict holding a **type of Security** for a **specific reason**

Or, rewritten as a constraint:

6. An Account must not hold a type of Security for a specific reason

Absent a method for accommodating many similar rules as a single, generalized case, we need to enter each specific rule separately into a Rulesheet. This makes the task of capturing, optimizing, testing, and managing these rules more difficult and time-consuming than necessary. In the example of **Trade Allocation**, an Account Restriction (as a Vocabulary term) might be associated with Account (as the "holder" or "owner" of the restriction), as well as other entities shown in the following figure. For illustration purposes, the Vocabulary is shown as a UML class diagram.

**Figure 175: UML Class Diagram of Sample Vocabulary**

With this Vocabulary, the following Rulesheet can be defined:

Entity/Attribute	Generic business rule
Security.type	An account must not hold a security of a restricted type
Issuer.name	An account must not hold a security issued by a restricted company
Industry.name	An account must not hold a security issued by a company in a restricted industry

**Figure 176: Parameterized Rule Example**

The screenshot shows the 'main.ers' application interface. On the left is a tree view of the rule scope, including Transaction [tx], Filters, account [ac], Filters, ac.name='Airbus', name, accountRestriction [ar], security, and type. Below the tree is a 'Filters' section with two entries: 1. ac.name='Airbus' and 2. (empty). The main area is divided into three sections: 'Conditions', 'Actions', and 'Rule Statements'.

**Conditions Table:**

	0	1	2	3
a	-	T	-	-
b	-	-	T	-
c	-	-	-	T
d				
e				
f				

**Actions Table:**

	0	1	2	3
A				
B				
C				
D				

**Rule Statements Table:**

Ref	ID	Post	Alias	Text
1	Violation	tx		Acct must not trade security of prohibited type [acct={ac.name}, type={ar.security.type}, rule={ar.businessRule}]
2	Violation	tx		Acct must not trade security of prohibited issuer [acct={ac.name}, issuer={ar.issuer.name}, rule={ar.businessRule}]
3	Violation	tx		Acct must not trade security of prohibited industry type [acct={ac.name}, industry={ar.industry.name}, rule={ar.businessRule}]

Note that `Transaction` is the scope for this Rulesheet because all included rules apply only to `Securities` related to a specific `Account` and contained in the same `Transaction`. (See the topic [Rule Scope and Context](#) for an in-depth explanation of Scope.) Also, note that the rule statements have been written as *generic* rules, with parameters appended to identify the *specific* examples involved in rule execution. This provides the user with a more complete explanation of which rule fired and why it fired.

The following Ruletest tests the second and third rule statements. A single transaction contains one account, `Airbus`, which has two account restrictions: `no competitor securities` and `no tobacco industry securities`. Two securities are included in the transaction, one for `Boeing` (a competitor) and one for `RJR` (a company in the tobacco industry). Running the Ruletest in the following figure, we see:

**Figure 177: Ruletest**

Note the Violation messages posted as a result of the rules firing.

## Populating an AccountRestriction table from a sample user interface

Parameterizing rules can improve reuse and simplify maintenance. In fact, maintenance of some well-defined rule patterns can be further simplified by enabling users to modify them *external* to Corticon Studio altogether. A user may define and maintain specific rules that follow the generic rule pattern (analogous to an *instance* of a generic rule *class*) using a graphical interface or database table built for this purpose.

The following is a sample user interface that could be constructed to manage parameterized rules that share similar patterns. Note, this sample interface is discussed here only as an example of a parameterized rule maintenance application. It is not provided as part of the Corticon Studio installation.

**Figure 178: Sample GUI Window for Populating a Rule's Parameter Table**

1. The user selects an Account for which the Account Restriction will be created. Referring back to our example, the user would select `Airbus` from the list box.
2. The user enters a specific business rule that provides the motivation for the Account Restriction. The prior example used `no competitor securities` and `no tobacco securities`.
3. The user selects the type of restriction being created. Our example used `issuer.name` and `industry.name`.
4. Once all components of the Account Restriction are entered and selected, clicking *Add Restriction* creates the restriction by populating the AccountRestriction table in an external database.

AccountRestriction table				
Account	Security.type	Issuer.name	Industry.name	Business Rule
Airbus	---	Boeing	---	No competitor securities
Airbus	---	---	Tobacco	No tobacco securities

5. After adding a restriction, it appears in the lower scrolling text box. Selecting the Business Rule in the scrolling text box and clicking *Delete Restriction* will remove it from the box and from the table.
6. The checkbox indicates an active or inactive Business Rule. This allows the user to deactivate a rule without deleting it. In practice, another attribute could be added to the `AccountRestriction` entity called `active`. A Precondition might filter out inactive rules to prevent them from firing during runtime.

**WARNING!**

Whenever you decide to maintain rule parameters outside of Corticon Studio, you run the risk of introducing ambiguities or conflicts into your Rulesheet. The Conflict Checker may not help you discover these problems since some of the rule data isn't shown in Corticon Studio. So always try to design your parameter maintenance forms and interfaces to prevent ambiguities from being introduced.

## Test yourself - questions – recognizing and modeling parameterized rules

---

**Note:** Try this test, and then go to **Answers:** [Recognizing & modeling parameterized rules](#) on page 288 to correct yourself.

---

1. When several rules use the same set of Conditions and Actions, but different values for each, we say that these rules share a common \_\_\_\_\_.
2. Another name for the different values in these expressions is \_\_\_\_\_.
3. True or False. When several rules share a pattern, the best way to model them is as a series of Boolean Conditions.
4. What's a potential danger of maintaining rule parameters outside of a Corticon Studio Rulesheet?
5. Write a generalized rule that identifies the pattern in the following rule statements:
  - Platinum customers buy \$100,000 or more of product each year
  - Gold customers buy between \$75,000 and less than \$100,000 of product each year
  - Silver customers buy more than \$50,000 and less than \$75,000 of product each year
  - Bronze customers buy between \$25,000 and \$50,000 of product each year
6. In the rules listed above, what are the parameters?
7. Describe the ways in which these parameters can be maintained. What are the advantages and disadvantages of each option?

---

## Writing Rules to access external data

---

Corticon rules can read from and write to an RDBMS. This feature is named Enterprise Data Connector or "EDC", and is sometimes referred to as Direct Database Access or "DDA".

---

**Note:** Documentation topics on EDC:

- The tutorial, *Using Enterprise Data Connector (EDC)*, provides a focused walkthrough of EDC setup and basic functionality.
- *Writing Rules to access external data* chapter in the *Rule Modeling Guide* extends the tutorial into scope, validation, collections, and filters.
- *Relational database concepts in the Enterprise Data Connector (EDC)* in the *Integration and Deployment Guide* discusses identity strategies, key assignments, catalogs and schemas, database views, table names and dependencies, inferred values, and join expressions.
- *Implementing EDC* in the *Integration and Deployment Guide* discusses the mappings and validations in a Corticon connection to an RDBMS.
- *Deploying Corticon Ruleflows* in the *Integration and Deployment Guide* describes the Deployment Console parameters for Deployment Descriptors and compiled Decision Services that use EDC.
- *Vocabularies: Populating a New Vocabulary: Adding nodes to the Vocabulary tree view* in the *Quick Reference Guide* extends its subtopics to detail all the available fields for Entities, Attributes, and Associations.

---

You should work through the procedural style of the *Corticon Tutorial: Using Enterprise Data Connector (EDC)* to experience configuring and using this new feature.

---

**Note:** The functionality described in this chapter requires that Studio is running in the **Integration & Deployment** mode, and, for your Server, that you have a license file that enables EDC. Contact Progress Software technical support or your Progress Software representative for additional details.

---

## Overview

When you create a Vocabulary, you use the properties of the Entities, Attributes, and Associations to define Rulesheets, Ruletests, and Ruleflows. Everything is local -- any data required by the rules is either entered as Ruletest input or is generated by the rules during execution.

Corticon EDC lets you define mappings to a database so that rules can “reach out” to access (query) a database directly, and then retrieve what it needs “on-the-fly” during execution, thus enriching the information available to the rules.

As useful as this capability is to the technical people responsible for Rulesheet deployment and integration, a rule modeler might ask “what’s the cost to me?” In designing EDC, Corticon made this capability as transparent to the rule modeler as possible. In other words, we don’t want the rule modeler to worry about where the data “fed” to Corticon Server is stored, how it’s retrieved and assembled, or how it is sent. We want the rule modeler to be concerned with getting the rules right, and let everything else follow from there. This is consistent with our declarative approach to rule modeling – modeling rules that express what to do, not how to do it.

This chapter focuses on the aspects of rule modeling that are affected by the Corticon Enterprise Data Connector.

For details, see the following topics:

- [A Scope refresher](#)
- [Validation of database properties](#)
- [Enabling Database Access for Rules using root-level Entities](#)
- [Precondition and Filters as query filters](#)
- [Test yourself - questions – Writing rules to access external data](#)

## A Scope refresher

As we have seen throughout this manual, the concept of scope is key to any solid understanding of rule design and execution. Scope in a rule helps define or constrain which data is included in rule processing, and which data is excluded. If a rule uses the Vocabulary term `FlightPlan.cargo.weight` then we know that those `FlightPlan` entities without associated `Cargo` entities will be ignored. How can we act upon a `FlightPlan.cargo.weight` if the `FlightPlan` doesn’t have an associated cargo? Obviously we can’t – and neither can Corticon Studio or Server.

But we also know that Vocabulary root-level entities – `FlightPlan`, for example – bring every instance of the entity into scope. This means that a rule using root-level `FlightPlan` acts on every instance of `FlightPlan`, including `Cargo.flightPlan`, `Aircraft.flightPlan`, or any other role using `FlightPlan` that may exist in our Vocabulary.

When we add the ability for the Corticon Server and Studio to dynamically retrieve data from a database, rule scope determines which data to retrieve. This is exactly the same concept as Studio determining which data in an Input Ruletest to process and which to ignore based upon a rule's scope. So if we write rules using root-level `FlightPlan`, then the Studio will process all `FlightPlans` present in the Input Ruletest during rule execution.

But with EDC's Direct Database Access, the amount of test data is no longer limited to that contained in a single Input Ruletest – it is limited by the size of the connected database. Rules using root-level `FlightPlan` (or any other root-level entity) will force the Server or Studio to retrieve ALL `FlightPlan` entities (records) from the database. If the database is very large, then that will mean a large amount of data is retrieved. For this reason, **database access for root-level rules is turned off by default**. This ensures that we do not accidentally force the Server to perform extremely large and time-consuming data retrievals from the database unless we explicitly require it.

## Validation of database properties

When EDC is enabled, the Vocabulary elements - Entity, Attribute, and Association - each have additional properties that can be entered by the user, or inferred from database metadata. Corticon EDC validates these Vocabulary-to-Database mappings, and displays error conditions in a window. There are three aspects to the database validation function:

### Dynamic Validation

Corticon Studio validates against imported database metadata as property values change in a Vocabulary. For example, for a database-persistent entity, if you specify a table name that does not exist in the database metadata, the system posts a validation message in the **Problems View**. Studio creates other error and warning validation messages depending on the severity of the issue detected, such as:

- Property values are explicitly contradicted by database metadata.
- You select a property value, then re-import metadata, only to find that the selected value no longer exists in the database schema.

Warnings are also created for “soft” errors, such as:

- If you designate a Vocabulary entity as datastore persistent, the system is unable to infer which database table best matches the entity name, dynamic validation issues a warning message.
- If the system is unable to unambiguously determine the join expression for a given association, the association is flagged as a warning until you select one of the allowable values.

---

**Note:** Dynamic validation is always performed against the imported copy of database metadata. You must ensure that metadata is imported into the Vocabulary whenever the database schema is modified.

---

### On-Demand Validation

In addition to dynamic validation, Corticon Studio provides the Vocabulary menu action **Validate Mappings** so that you can validate the Vocabulary, as a whole, against the database schema. Unlike dynamic validation, on-demand validation is performed against the actual schema so it is considered the definitive test of Vocabulary mappings.

## Validation at Deployment

Corticon Server leverages on-demand validation functionality whenever a decision service is deployed. If Corticon Server detects a problem, it throws an exception and prevents deployment.

**Note:** Deployment-time validation check can be turned off in a server property file in (`CcServer.properties`) to “force” deployment despite mapping errors if circumstances warrant it.

## Enabling Database Access for Rules using root-level Entities

Since database access for rules using root-level terms is disabled by default, we need to know how to enable it for those circumstances when we do want it. We call this “extending” a root-level entity to the database. To illustrate, we’ll use a simple rule based on the same `Cargo.ecore` used elsewhere in this manual, the *Corticon Studio: Basic Rule Modeling Tutorial*, and the *Corticon Tutorial: Using Enterprise Data Connector (EDC)*.

The process of connecting this particular Vocabulary to an external database is discussed in detail in the EDC tutorial. While the mechanics of this connection may not be of much interest (or importance) to a rule modeler, we do need to be comfortable with Studio Test behavior when connected to an external database in order to focus on what *extending to a database* really means to our rule expressions.

Figure 179: Sample Rulesheet

The screenshot displays the Corticon Studio Rulesheet interface. The top pane shows the 'CargoLoad.ers' file with a 'Scope' tree on the left containing entities like Aircraft, Cargo, and FlightPlan. The main area is divided into 'Conditions' and 'Actions' sections. The 'Conditions' section has a table with 5 rows (a-e) and 5 columns (0-4). Row 'a' contains the condition 'load.weight -> sum > plane.maxCargoWeight' and has a 'T' in column 1. The 'Actions' section has a table with 5 rows (A-E) and 5 columns (0-4). Row 'A' contains the action 'Post Message(s)' and has an envelope icon in column 1. The bottom pane shows 'Rule Statements' with a table containing one rule (Ref 1, ID Load, Post Violation, Alias plane, Text: 'The {{plane.tailNumber}} must not be assigned to flightplan {{plan.flightNumber}} because the assigned cargo weighs too much.').

Conditions	0	1	2	3	4
a	load.weight -> sum > plane.maxCargoWeight	T	F		
b					
c					
d					
e					

Actions	0	1	2	3	4
A	Post Message(s)	✉			
B					
C					
D					

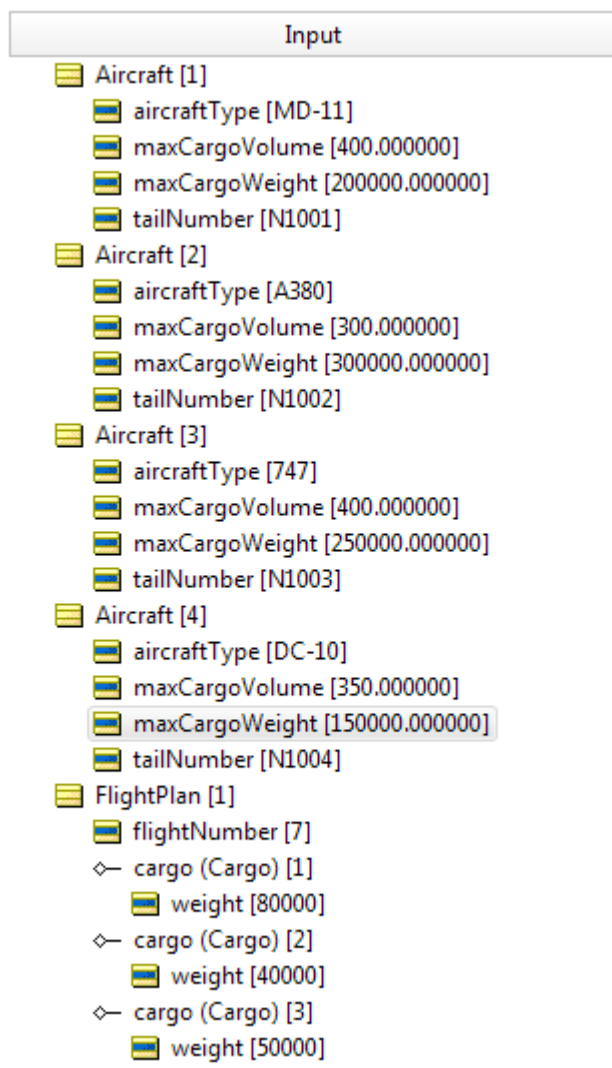

Ref	ID	Post	Alias	Text	Rule Name
1	Load	Violation	plane	The {{plane.tailNumber}} must not be assigned to flightplan {{plan.flightNumber}} because the assigned cargo weighs too much.	

The Rulesheet shown above simply adds up (sums) the collection (you may want to review the Collections chapter for a refresher on this operator or collections in general) of `Cargo` weights associated with a `FlightPlan` (`load.weight`) and compares this to the `maxCargoWeight` of the root-level `Aircraft`. Our intention is to perform this comparison for every available `Aircraft`, so we have used the root-level `Aircraft` in our Conditional expression. Any `Aircraft` whose `maxCargoWeight` is inadequate will be identified with a posted `Violation` message.

## Testing the Rulesheet with Database Access disabled

Testing this Rulesheet without database access is a simple matter of building an Input Ruletest with all necessary data. An example of this is a Ruletest we create against the `Cargo.ecore` named `CargoLoad.ert`. Its input data is as shown:

**Figure 180: Sample Input Ruletest**

Looking at this Input Ruletest, we see a single `FlightPlan` with its collection of `Cargo` this collection is what we're representing with the alias `load` in our Rulesheet's Scope section. Each `Cargo` has a `weight` value entered.

The four root-level `Aircraft` entities are also shown. Each one has a `maxCargoWeight`, which will be compared to the sum of `load.weight` during rule execution.

Given what we know about rule scope, we can confidently predict that the test data provided in this Input Ruletest will be processed by the Rulesheet because it contains the same scope!

In the following figure, we've executed the Test and see that it functioned as expected. Since `load.weight` sums to 170000 lbs. and the Aircraft with `tailNumber` N1004 can only carry 150000 pounds, we receive a Violation message for that Aircraft and that Aircraft alone. All other Aircraft have `maxCargoWeight` values of 200000 or more, so they fail to fire the rule.

**Figure 181: Ruletest Violation Message**

Rule Messages	
Severity	Message
Violation	[N1004] must not be assigned to flightplan [7] because the assigned cargo weighs too much.

So far, this behavior is exactly what we have come to expect from rules – they process data of the same scope.

Save the `CargoLoad.ert` Ruletest

## Testing the Rulesheet with Database Access enabled

First, let's update the database we have been using in the EDC tutorial to prepare for the features that we want to demonstrate. The Ruletest we just created, `CargoLoad.ert`, has the aircraft data we want including the primary key, the `tailNumber`. It actually extends the tutorial's data with one added row. But it has cargo info we want to keep aside for now.

We'll copy the Ruletest, drop those unwanted inputs, and then update the database.

**Note:** The procedure for connecting and mapping a Vocabulary to an external database, and setting an Input Ruletest to access that database in **Read Only** and **Read/Update** modes is described fully in the *EDC Tutorial*.

To load the aircraft data:

1. In the Rule Project Explorer, copy and paste the `CargoLoad.ert` file. Name the copy `AircraftLoader.ert`.
2. Open `AircraftLoader.ert`.
3. In the Input area, click on `FlightPlan`, and then press **Delete**.
4. Select the menu option **Ruletest > Testsheet > Database Access > Read/Update**.
5. Select the menu command **Ruletest > Testsheet > Run Test**.

Look at the `Aircraft` table in the database. You see the updated values and the new row:

dbo.Aircraft				
	tailNumber	aircraftType	maxCargoVolume	maxCargoWeight
	N1001	747	400.00	250000.00
	N1002	DC-10	300.00	150000.00
	N1003	DC-10	400.00	200000.00
	N1004	747	350.00	250000.00
▶*	NULL	NULL	NULL	NULL

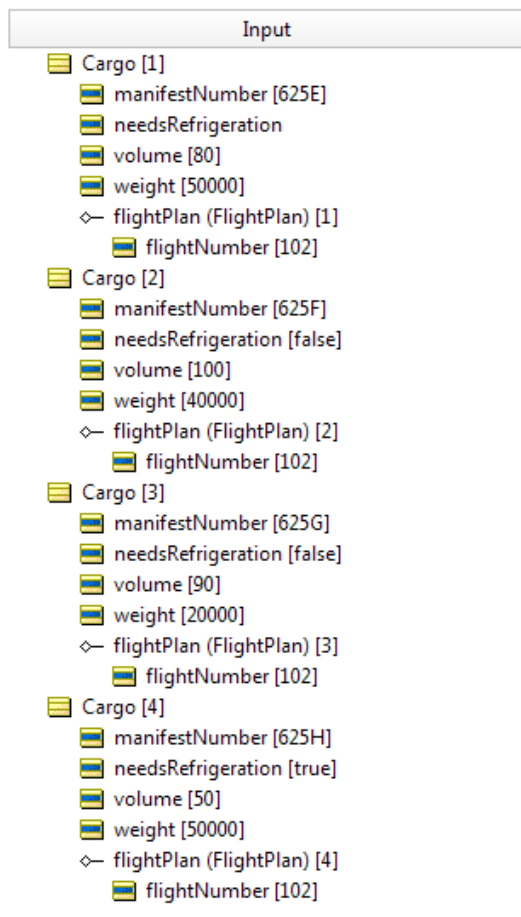

To make the test effective, we need to add some heavy cargo to one of the flight plans. Here, we created four SQL query lines to add four new Cargo manifests to one flight:

```
INSERT INTO Cargo.dbo.Cargo
    (manifestNumber,RflightPlanAssoc_flightNumber,
     needsRefrigeration,container,volume,weight)
VALUES ('625E',102,null,null,80,50000);
INSERT INTO Cargo.dbo.Cargo
    (manifestNumber,RflightPlanAssoc_flightNumber,
     needsRefrigeration,container,volume,weight)
VALUES ('625F',102,0,null,100,40000);
INSERT INTO Cargo.dbo.Cargo
    (manifestNumber,RflightPlanAssoc_flightNumber,
     needsRefrigeration,container,volume,weight)
VALUES ('625G',102,0,null,90,20000);
INSERT INTO Cargo.dbo.Cargo
    (manifestNumber,RflightPlanAssoc_flightNumber,
     needsRefrigeration,container,volume,weight)
VALUES ('625H',102,1,null,50,50000);
```

Copy the text in the codeblock and paste it into a new SQL Query in your database, and execute it.

**Note:** You could also create a Ruletest, CargoLoader, with these values and the associated flightPlan, entering the values as shown, and then running the test in **Read/Update** mode:

**Figure 182: Using a Ruletest to add Cargo rows to the connected external database**

The `Cargo` table now shows that there are eight items, five of which are assigned to one flight:

**Figure 183: Cargo Table from Database**

	manifestNumber	container	needsRefrigeration	volume	weight
▶	625A	NULL	NULL	10	1000
	625B	oversize	False	40	1000
	625C	NULL	False	20	30000
	625D	NULL	True	10	1000
	625E	NULL	NULL	80	50000
	625F	NULL	False	100	40000
	625G	NULL	False	90	20000
	625H	NULL	True	50	50000

**Note:** We are not evaluating container requirements in these exercises.

## Setting up the test

Let's create a new Ruletest that uses the test subject we created earlier, the `CargoLoaders` Rulesheet: [CargoLoad Rulesheet](#). We will create a new Input Ruletest that just takes the `FlightPlan` entity from the scope, and then enter the `flightNumber` value 102. When we run the test, the Output is identical to the input and there are no messages. That seemed to do nothing:

**Figure 184: Ruletest of FlightPlan Seed Data**

Input	Output
<ul style="list-style-type: none"> <li>FlightPlan [1] <ul style="list-style-type: none"> <li>flightNumber [102]</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>FlightPlan [1] <ul style="list-style-type: none"> <li>flightNumber [102]</li> </ul> </li> </ul>

Notice that the only data necessary to provide in the Input Ruletest is a `FlightPlan.flightNumber` value – since this attribute serves as the primary key for the `FlightPlan` table, Studio has all the “seed data” it needs to retrieve the associated `Cargo` records from the `Cargo` database table. In addition to retrieving the `load.weight` collection, we also needed all `Aircraft` records from the `Aircraft` table. But this didn't happen – no `Aircraft` records were retrieved, so the rule's comparison couldn't be made, so the rule couldn't fire. We should have expected this since we have already learned that database access for root-level terms is disabled by default.

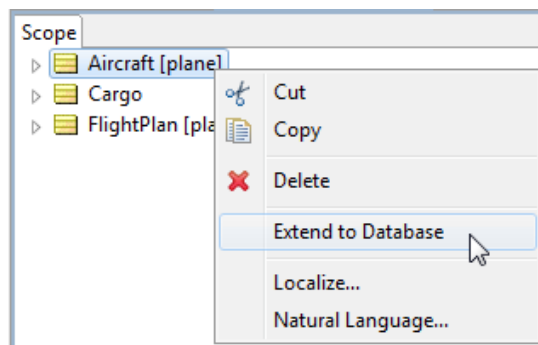

Let's set the Ruletest to read data from the database and return everything that it finds. Toggle the menu options in the **Ruletest > Testsheet** menu as shown:

When we run the test again, the output is still the same as the input and there are no messages.

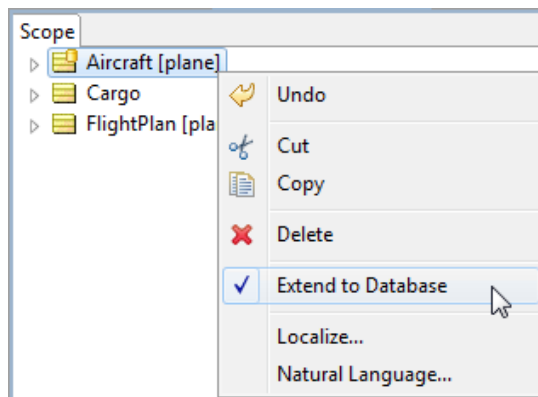

## Extend to Database

What we want to do now is set the Rulesheet to **Extend to Database**, and then see how it impacts the test. On the `CargoLoad.ers` Rulesheet, right-click `Aircraft` in the **Scope** area, and then select **Extend to Database**, as shown:

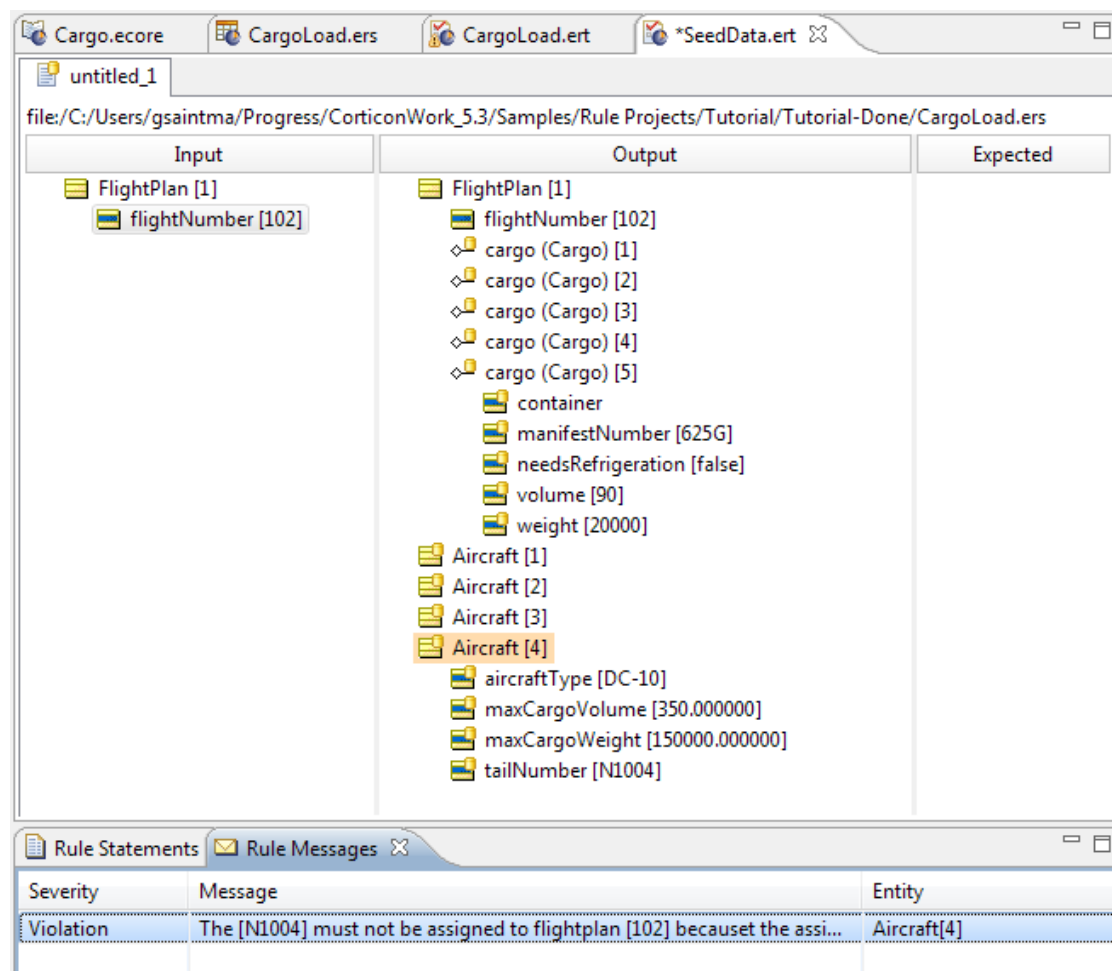

Once selected, the option shows a checkmark, and the `Aircraft` icon in the **Scope** is decorated with a database icon, as shown:

**Figure 185: A Root-Level Scope Row Extended to the Database**

Save your Rulesheet to ensure that these changes take effect. Now, retest the same Input Ruletest shown in [Input Ruletest with Seed Data](#). The results are as follows:

**Figure 186: Results Ruletest Showing a Successful Extend-to-Database Retrieval**

*These results are much different!* Corticon has successfully retrieved all `Aircraft` records, performed the summation of all the cargo in the given flightplan, and identified an `Aircraft` record that fails the test. Given this set of sample data, it is the `Aircraft` with `tailNumber N1004` that receives the `Violation` message.

## Returning all instances can be overwhelming

While this rich relational data retrieval is good to see, we are only have four planes and five packages in the flight plan. What if we have 1,000 planes and hundreds of thousands of packages every day? That amount of data would be overwhelming. So what we can do is constrain the return data to just relevant new information by toggling the Ruletest's return option to **Return Incoming/New Entity Instances Only**, as shown:

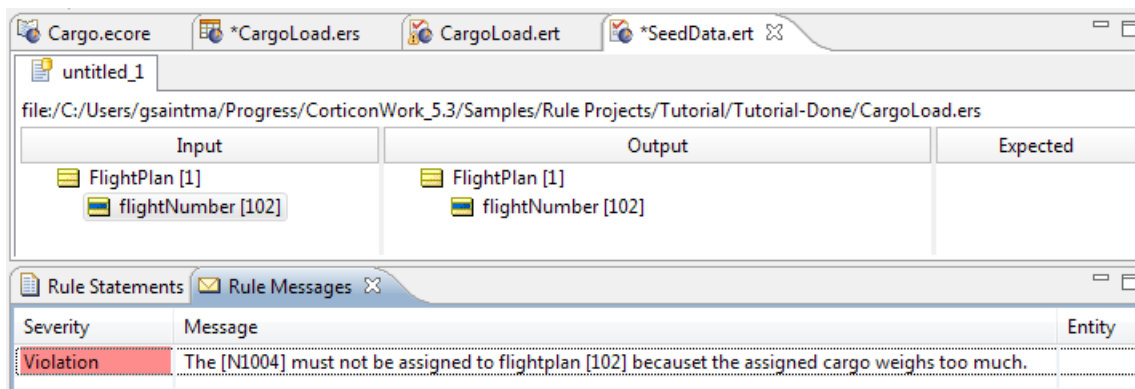

The data that returns is drawn only from those entities that were:

- Directly used in the rules.
- Present in the request message.
- Generated by the rules (if any).

**Note:** This option can be set in Deployment Descriptor file (.cdd), or as a parameter in the 9-parameter version of `addDecisionService` method in the Server API scripts.

When you run the Ruletest now, the output is unchanged yet we got the Violation message as to which plane cannot be assigned that flight plan.

That result is concise, providing what could be all we really wanted to know in this test.

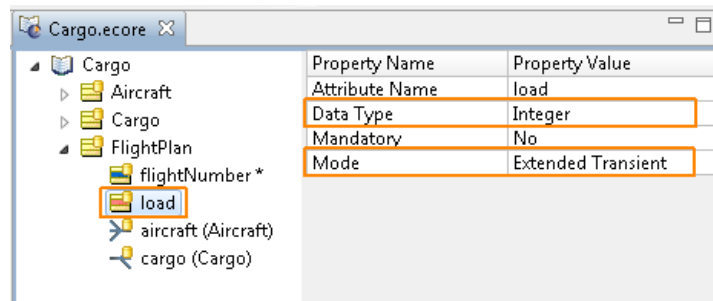

## Optimizing Aggregations that Extend to Database

Our rulesheet used a condition statement that did a calculation and a difference, calling a statement when it evaluated as `true`, as shown:

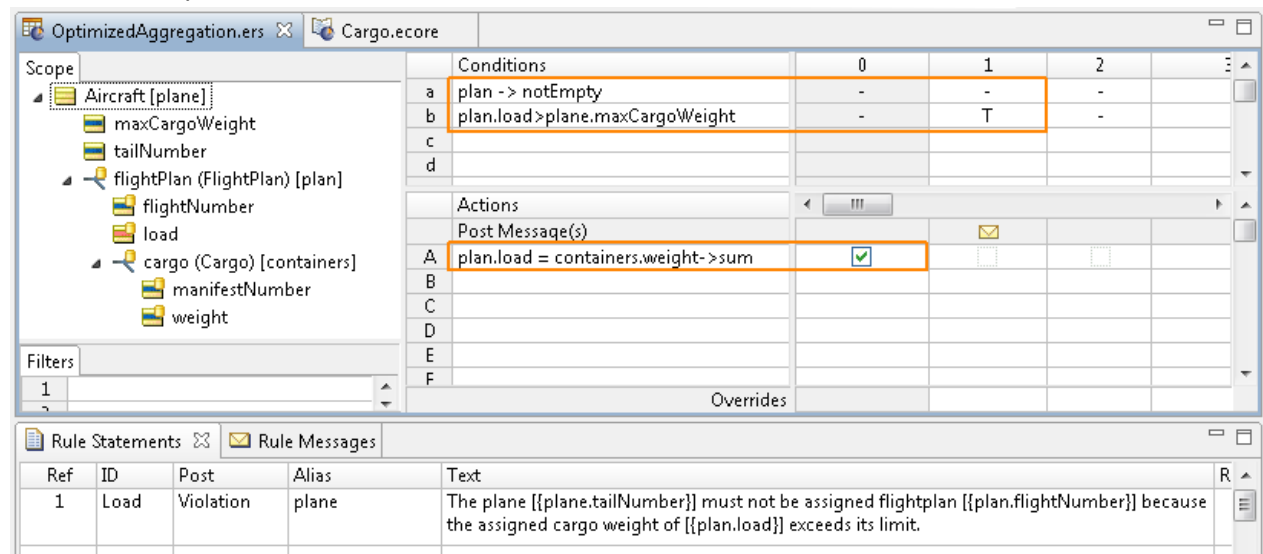

As written, `load.weight ->sum > plane.maxCargoWeight`, the condition will copy all the relevant cargo records into Corticon's memory to perform its `sum`, and then evaluate whether total weight is greater than the plane's capacity. As we are extended to database, the number of values could be large. Corticon lets you optimize such calculations for non-conditional (column 0) actions.

You can recast the conditions by creating an attribute in the `FlightPlan` entity to store a calculation. Here, we created the `load` attribute, and then set its properties so that the Data Type, Integer is the same as the `weight` data it will aggregate, and setting the Mode to `Extended Transient` as this is data that will be just used locally:

You could rewrite the conditions and actions to create a non-conditional rule followed by a conditional test of the computed result, as follows:

This optimizes the performance by calculating `load` on the database-side, and then evaluating the `load` against `maxCargoWeight` in memory.

**Note:** This feature applies to all Collection operators that are **aggregation** operators: `sum`, `avg`, `size`, `min`, and `max`. See [Aggregations that optimize database access](#) on page 119 for more information about these Collection operators.

## Precondition and Filters as query filters

When the Enterprise Data Connector is in use, Scope rows in a Rulesheet can act as queries to an external database. When an alias definition is designated as **Extend to Database**, the scope of the alias is assumed to include all database records in the Entity's corresponding table. But we often want or need to qualify those queries to further constrain the data returned to Server or Studio. You can think of conditional clauses written in the Preconditions/Filters section of the Rulesheet as placing constraints on these queries. If you are familiar with structured query languages (SQL), then you may recognize these constraints as "WHERE clauses" in a SQL query.

If you are not familiar with SQL, that's OK. Review the [Filters& Preconditions](#) chapter of this manual to learn more about how a **Precondition/Filter** expression serves to reduce or “filter” the data in working memory so that only the data that satisfies the expression “survives” to be evaluated and processed by other rules on the same Rulesheet. EDC simply extends working memory to an external database; the function of the Precondition/Filter expression remains the same.

For performance reasons, it is often desirable to perform a complete query -- including any *WHERE* clauses -- inside the database before returning the results set (the data) to Studio or Server. An unconstrained or unfiltered results set from an external database may be very large, and takes time to transfer from the database to Studio or Server. Once the results set has entered Studio's or Server's working memory, then Preconditions/Filters expressions serve to reduce (or filter) the results set further before rules are applied. But if we believe the unfiltered results set will take too much time to transfer, then we may decide to execute the Preconditions/Filters expressions inside the database query, thereby reducing the results set prior to transmission to Studio or Server. This may make the entire database access process faster.

## Filter Query qualification criteria

When **any** of the following are true, the Precondition/Filter expression **does not qualify** as a Query Filter:

1. If it does not contain at least one alias which has been extended to the database.
2. If it contains any attributes of Boolean datatype. Boolean datatypes are implemented inconsistently in commercial RDBMS, and cannot be included in Query Filters.
3. If it uses an operator not supported by databases (see list below)
4. If it references more than one alias not extended to database.

## Operators supported in Query Filters

Query Filters are Corticon Rule Language expressions which are performed in the database. As such, the operators used in these expressions must be compatible with the database's native query language, which is always based on some form of SQL. Not all Corticon Rule Language operators have comparable functions in SQL. Those operators supported by standard SQL and therefore also permitted in Query Filters are shown in the table below:

**Table 4: Operators supported by Query Filters**

Operator Name	Operator Syntax	Datatypes Supported
Equal To (comparison)	=	DateTime, Decimal, Integer, String
Not Equal To	<>	DateTime, Decimal, Integer, String
Less Than	<	DateTime, Decimal, Integer, String
Greater Than	>	DateTime, Decimal, Integer, String

Operator Name	Operator Syntax	Datatypes Supported
Less Than or Equal To	<code>&lt;=</code>	DateTime, Decimal, Integer, String
Greater Than or Equal To	<code>&gt;=</code>	DateTime, Decimal, Integer, String
Absolute Value	<code>.absval</code>	Decimal, Integer
Character Count	<code>.size</code>	String
Convert to Upper Case	<code>.toUpper</code>	String
Convert to Lower Case	<code>.toLowerCase</code>	String
Substring	<code>.substring</code>	String
Equal To (comparison)	<code>.equals</code>	String
Collection is Empty	<code>-&gt;isEmpty</code>	Collection
Collection is not Empty	<code>-&gt;notEmpty</code>	Collection
Size of Collection	<code>-&gt;size</code>	Collection
Sum	<code>-&gt;sum</code>	Collection
Average	<code>-&gt;avg</code>	Collection
Minimum	<code>-&gt;min</code>	Collection
Maximum	<code>-&gt;max</code>	Collection
Exists	<code>-&gt;exists</code>	-

**Note:** The Collection operators listed above must be used directly on the extended-to-database alias in order to qualify as a Query Filter. If the collection operator is used on an associated child alias of the extended-to-database alias, then the expression is processed in memory.

## Using multiple filters in Filter Queries

One or more filters can be set as a database filter. When multiple filters are set as database filters, Corticon logically combines them with the `AND` operator to form one database query.

**Note:** If the database filters have different entity/alias references they will not be logically combined into one query. Each filter will execute in processing order. To determine which expression gets processed first, generate an execution sequence diagram by choosing **Rulesheet > Rulesheet > Execution Sequence Diagram** from Studio's menubar.

Consider the filters:

- `Customer.age > 18`
- `Customer.status = 'GOLD'`

the result is one database query:

```
Select * from Customer where age > 18 and status = "GOLD"
```

However, when the two filters are:

- `Customer.age > 18`
- `Order.total > 1000`

the result is two database queries (because Customer and Order are not logically related):

```
Select * from Customer where age > 18
```

```
Select * from Order where total > 1000
```

When the database filter contains more than one database entity/alias -- a compound filter -- it still acts as a single query. For example:

- `Order.bid >= Item.price`

which results in the query:

```
Select * from Order o,Item i where o.bid > i.price
```

When there are multiple filters related to one or more of the entities in a compound filter, they are combined with the AND operator. For example, consider the filters:

- `Order.bid >= Item.price`
- `Order.status = 'VALID'`
- `Item.qty > 0`

which results in the query:

```
Select * from Order o,Item I where o.bid > i.price and o.status = "VALID"
and i.qty > 0
```

## Test yourself - questions – Writing rules to access external data

---

**Note:** Try this test, and then go to **Answers:** [Logical analysis & optimization](#) on page 289 to correct yourself.

---

1. Rule scope determines which \_\_\_\_\_ is processed during rule execution.
2. Why is root-level database access disabled by default?
3. When a Scope row is shown in bold text, what do we know about that entity's database access setting?
4. True or False. Only root-level entities can be extended to a database.

5. Which documents explain in more detail how the Direct Database Access feature works?
6. In general, does a rule author need to care about where actual data is stored, how it is retrieved, or how it is sent to the rules when creating Rule Sets?
7. Are there any exceptions to the general rule you defined in the question above?

## Logical analysis and optimization

---

For details, see the following topics:

- [Testing, analysis, and optimization](#)
- [Traditional means of analyzing logic](#)
- [Using Corticon Studio to validate rulesheets](#)
- [Logical loop detection](#)
- [Optimizing rulesheets](#)
- [Test yourself - questions – logical analysis and optimization](#)

### Testing, analysis, and optimization

Corticon Studio provides the rule modeler with tools to test, validate, and optimize rules and Rulesheets prior to deployment. Before proceeding, let's define these terms.

## Scenario testing

Scenario testing is the process of comparing *actual* decision operation to *expected* operation, using data scenarios or test cases. The Ruletest provides the capability to build test cases using real data, which may then be "fed" to a set of rules for evaluation. The actual output produced by the rules may then be compared to the output we expect those rules to produce. If the actual output matches the expected output, then we may have *some* degree of confidence that the decision is performing properly. Why only *some* confidence and not *complete* confidence will be addressed over the course of this chapter.

## Rulesheet analysis & optimization

Analysis and optimization is the process of examining and correcting or improving the logical construction of Rulesheets, *without* using test data. As with testing, the analysis process verifies that our rules are functioning correctly. Testing, however, does nothing to inform the rule builder about the execution efficiency of the Rulesheets. Optimization of the rules ensures they execute most efficiently, and provide the best performance when deployed in production.

The following example illustrates the point:

Two rules are implemented to profile life insurance policy applicants into two categories, high risk and low risk. These categories might be used later in a business process to determine policy premiums.

**Figure 187: Simple Rules for Profiling Insurance Policy Applicants**

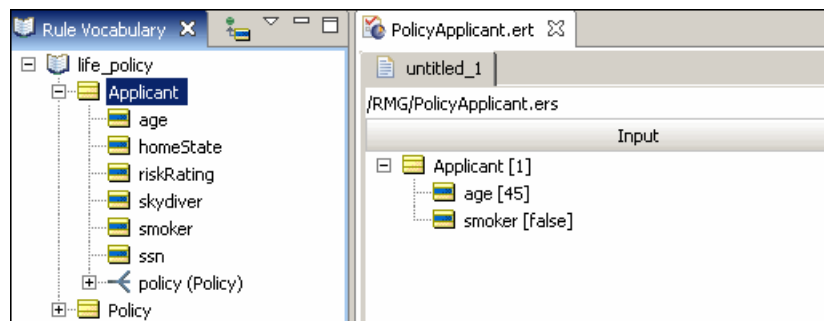

Conditions		0	1	2
a	Applicant.age		<= 55	-
b	Applicant.smoker		-	T
c				
d				
Actions				
Post Message(s)			✉	✉
A	Applicant.riskRating		'low risk'	'high risk'
B				
Overrides				

Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk

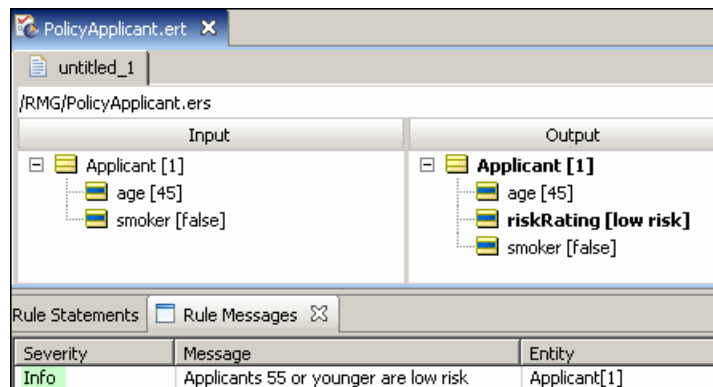

To test these rules, we create a new scenario in a Ruletest, as shown in A Test Scenario Created in a Ruletest.

**Figure 188: A Test Scenario Created in a Ruletest**

In this scenario, we have created a single example of `Person`, a non-smoker aged 45. Based on the rules we just created, we expect that the Condition in Rule 1 will be satisfied (*People aged 55 or younger...*) and that the person's `riskRating` will be assigned the value of `low`. To confirm our expectations, we run the Ruletest:

**Figure 189: Ruletest**

As we see in that figure, our expectations are confirmed: Rule 1 fires and `riskRating` is assigned the value of `low`. Furthermore, the `.post` command displays the appropriate rule statement. Based on this single scenario, can we say conclusively that these rules will operate properly for other possible scenarios; i.e., for all instances of `Person`? How do we answer this critical question?

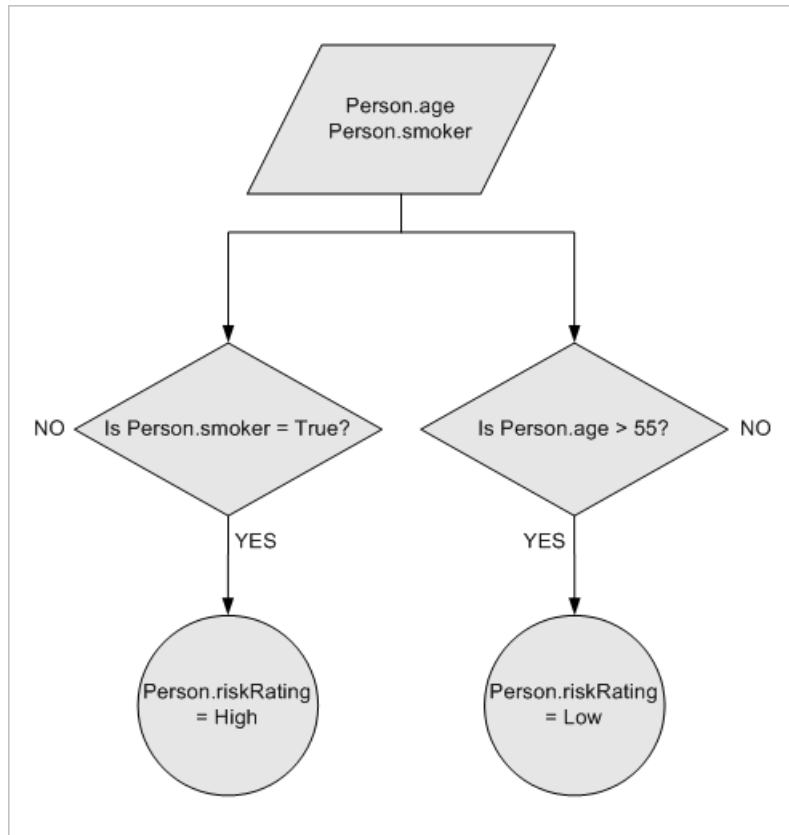

## Traditional means of analyzing logic

The question of proper decision operation for all possible instances of data is fundamentally about analyzing the logic in each set of rules. Analyzing each individual rule is relatively easy, but business decisions are rarely composed of just a single rule. More commonly, a decision is composed of dozens or hundreds of rules, and the ways in which the rules interact can be very complex. Despite this complexity, there are several traditional methods for analyzing sets of rules to discover logical problems.

## Flowcharts

A flowchart that captures these two rules might look like the following:

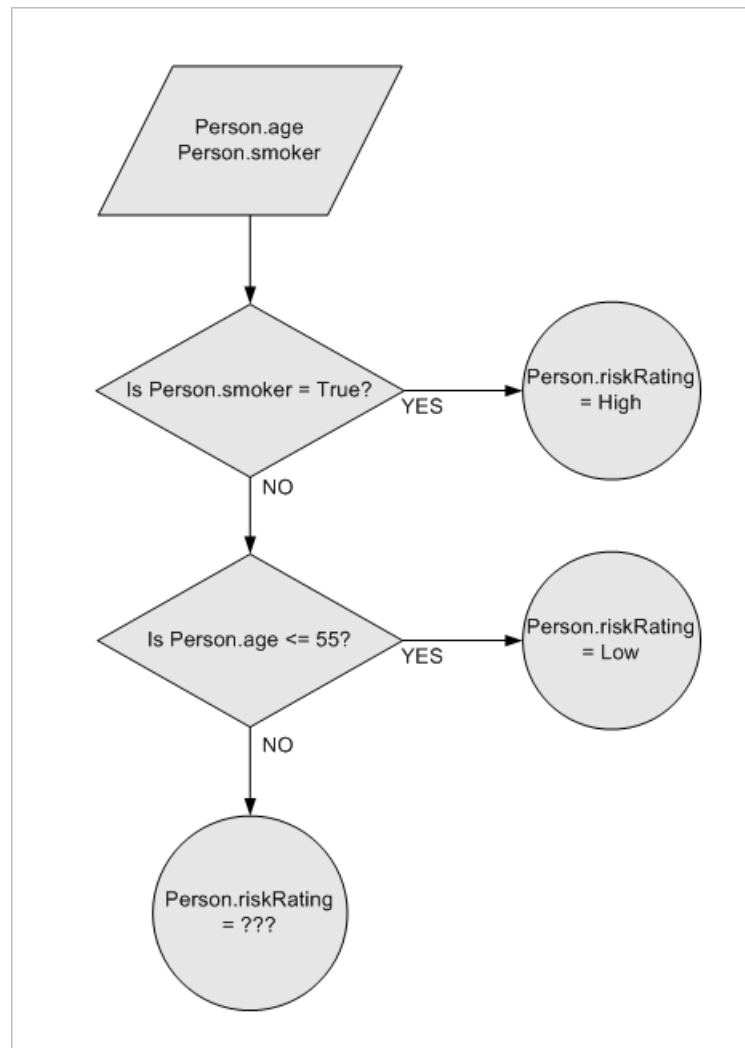

**Figure 190: Flowchart with 2 Rules**

Upon closer examination, the flowchart reveals two problems with our rules: what Action(s) should be taken if either test fails, in other words, if `Person.age > 55` or if `Person.smoker = false`? The rules built in [Simple Rules for Profiling Insurance Policy Applicants](#) do not handle these two cases. But there is also a third, subtler problem here: what happens if **both** Conditions are satisfied, specifically when `Person.age <= 55` **and** `Person.smoker = true`? When `Person.age <= 55`, we want `Person.riskRating` to be given the value of low. But when `Person.smoker = true`, we want `Person.riskRating` to be given the value of high.

We have discovered a dependency between our rules – they are not truly separate and independent evaluations because they both assign a value to the same attribute. So the flowchart we began with turns out to be an incorrect graphical representation of our rules, because the decision flow does not truly follow two parallel and independent paths. Let's try a different flowchart:

**Figure 191: Flowchart with 2 Dependent Rules**

In the flowchart in Flowchart with 2 Dependent Rules, we have acknowledged an interdependence between the two rules, and have arranged them accordingly. However, a few questions still exist. For example, why did we choose to place the smoker rule *before* the age rule? By doing so we are giving the smoker rule an implicit priority over the age rule because any smoker will immediately be given a `riskRating` value of `High` regardless of what their `age` is. Is this what the business intends, or are we as modelers making unjustified assumptions?

We call this a problem of **logical conflict**, or **ambiguity** because it's simply not clear from our two rules, as they have been written, what the correct outcome should be. Does one rule take priority over the other? *Should* one rule take priority over the other? This is, of course, a business question, but the rule writer must be aware of the dependency problem and resulting conflict in order to ask the question in the first place. Also, notice that there is still no outcome for a non-smoker older than 55. We call this a problem of **logical completeness** and it must be taken into consideration, no matter which flowchart we use.

The point we are making is that discovery of logical problems in sets of rules using the flowcharting method is very difficult and tedious, especially as the number and complexity of rules in a decision (and the resulting flowcharts) grows.

## Test databases

The use of a test database is another common method for testing rules (or any kind of business logic, for that matter). The idea is to build a large number of test cases, with carefully chosen data, and determine what the correct system response should be for each case.

Then, the test cases are processed by the logical system and output is generated. Finally, the *expected* output is compared to the *actual* output, and any differences are investigated as possible logical bugs.

Let's construct a very small test database with only a few test cases, determine our expected outcomes, then run the tests and compare the results. We want to ensure that our rules execute properly for all cases that might be encountered in a "real-life" production system. To do this, we must create a set of cases that includes **all** such possibilities.

In our simple example of two rules, this is a relatively straightforward task:

**Table 5: Table: All Combinations of Conditions in Table Form**

condition	Smoker (smoker = true)	Non-Smoker (smoker = false)
Age <= 55		
Age > 55		

In this table, we have assembled a matrix using the Values sets from each of the Conditions in our rules. By arranging one set of values in rows, and the other set in columns, we create the Cross Product (also known as the *direct product* or *cross product*) of the two Values sets, which means that every member of one set is paired with every member of the other set. Since each Values set has only two members, the Cross Product yields 4 distinct possible combinations of members (2 multiplied by 2). These combinations are represented by the *intersection* of each row and column in the table above. Now let's fill in the table using the expected outcomes from our rules.

Rule 1, the age rule, is represented by row 1 in the table above. Recall that rule 1 deals exclusively with the age of the applicant and is not impacted by the applicant's smoker value. To put it another way, the rule produces the same outcome *regardless* of whether the applicant's smoker value is `true` or `false`. Therefore, the action taken when rule 1 fires (`riskRating` is assigned the value of `low`) should be entered into both cells of row 1 in the table, as shown:

**Figure 192: Rule 1 Expected Outcome**

condition	Smoker (smoker = true)	Non-Smoker (smoker = false)
Age <= 55	low	low
Age > 55		

Likewise, rule 2, the smoker rule, is represented by column 1 in the table above, **All Combinations of Conditions in Table Form**. The action taken if rule 2 fires (*riskRating* is assigned the value of *high*) should be entered into both cells of column 1 as shown:

**Figure 193: Rule 2 Expected Outcome**

condition	Smoker (smoker = true)	Non-Smoker (smoker = false)
Age <= 55	low, high	low
Age > 55	high	

The table format illustrates the fact that a complete set of test data should contain four distinct cases (each cell corresponds to a case). Rearranging, our test cases and expected results can be summarized as follows:

**Figure 194: Test Cases Extracted from Cross Product**

Test case	age	smoker	Expected outcome
1	<= 55	true	low, high
2	<= 55	false	low
3	> 55	true	high
4	> 55	false	

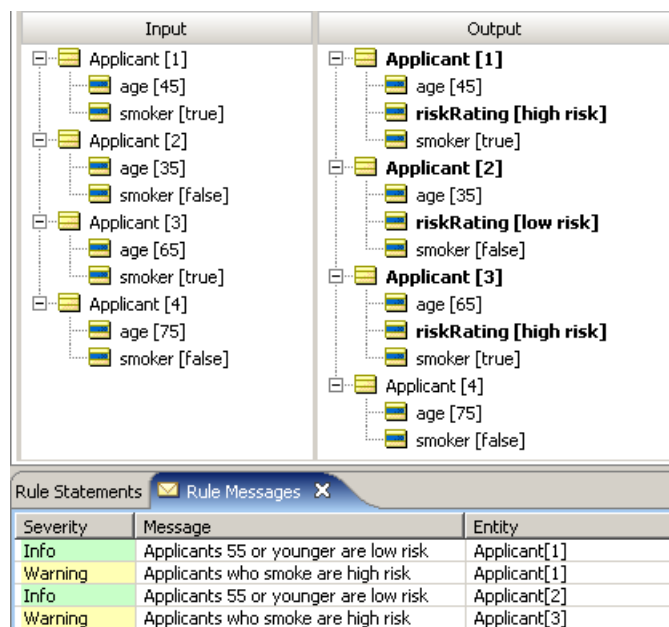

The table format also highlights two problems we encountered earlier with flowcharts. In the figure **Rule 2 Expected Outcome**, row 1 and column 1 intersect in the upper left cell (this cell corresponds to test case #1 in the figure above). As a result, each rule tries to assert its own action – one rule assigns a *low* value, and the other rule assigns a *high* value. Which rule is correct?

Logically speaking, they both are. But if the rule analyst had a *business* preference, it was certainly lost in the implementation. As before, we simply can't tell by the way the two rules are expressed. Logical conflict reveals itself once more.

Also notice the lower right cell (corresponding to test case #4) – it is empty. The combination of *age>55* **AND** non-smoker (*smoker=false*) produces no outcome because neither rule deals with this case – the logical incompleteness in our business rules reveals itself once more.

Before we deal with the logical problems discovered here, let's build a Ruletest in Studio that includes all four test cases in the figure above.

**Figure 195: Inputs and Outputs of the 4 Test Cases**

Let's look at the test case results in the figure above. Are they consistent with our expectations? With a minor exception in case #1, the answer is yes. In case #1, `riskRating` has been assigned the value of `high`. But also notice the rule statements posted: case #1 has produced two messages which indicate that both the age rule and the smoker rule fired as expected. But since `riskRating` can hold only one value, the system non-deterministically (at least from our perspective) assigned it the value of `high`.

So if using test cases works, what is wrong with using it as part of our Analysis methodology? Let's look at the assumptions and simplifications made in the previous example:

1. We are working with just two rules with two Conditions. Imagine a rule pattern comprising three Conditions – our simple 2-dimensional table expands into three dimensions. This may still not be too difficult to work with as some people are comfortable visualizing in three dimensions. But what about four or more? It is true that large, multi-dimensional tables can be "flattened" and represented in a 2-D table, but these become very large and awkward very quickly.
2. Each of our rules contains only a single Conditional parameter limited to only two values. Each also assigns, as its Action, a single parameter which is also limited to just two values.

When the number of rules and/or values becomes very large, as is typical with real-world business decisions, the size of the Cross Product rapidly becomes unmanageable. For example, a set of only six Conditions, each choosing from only ten values produces a Cross Product of  $10^6$ , or one *million* combinations. Manually analyzing a million combinations for conflict and incompleteness is tedious and time-consuming, and still prone to human error.

In many cases, the potential set of cases is so large, that few project teams take the time to rigorously define all possibilities for testing. Instead, they often pull test cases from an actual database populated with real data. If this occurs, conflict and incompleteness may never be discovered during testing because it is unlikely that every possible combination will be covered by the test data.

# Using Corticon Studio to validate rulesheets

Now, having demonstrated how to test rules with real cases (as performed in [Inputs and Outputs of the 4 Test Cases](#)) as well as having discussed two manual methods for developing these test cases, it is time to demonstrate how Corticon Studio performs conflict and completeness checking automatically.

## Expanding rules

Returning to our original rules (reproduced from [Simple Rules for Profiling Insurance Policy Applicants](#)):

Figure 196: Simple Rules for Profiling Insurance Policy Applicants

Rule Statements

Rule Messages

Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk

As illustrated by the table in [Rule 1 Expected Outcome](#), rule 1 (the age rule) is really a combination of two *sub-rules*; we specified an age value for the first Condition but did not specify a smoker value for the second Condition. Because the smoker Condition has two possible values (`true` and `false`), the two sub-rules can be stated as follows:

1. Applicants aged 55 or younger **AND** who do not smoke are assigned a risk rating of low risk

2. Applicants aged 55 or younger **AND** who do smoke are assigned a risk rating of low risk

Corticon Studio makes it easy to view sub-rules for any or all columns in a Rulesheet. By clicking the **Expand Rules**  button on the toolbar, or simply double-clicking the column header, Corticon Studio will display sub-rules for any selected column. If no columns are selected, then all sub-rules for all columns will be shown. Sub-rules are labeled using Decimal numbers: rule 1 below has two sub-rules labeled 1.1 and 1.2. Sub-rules 1.1 and 1.2 are equivalent to the upper left and upper right cells in [Rule 1 Expected Outcome](#).

**Figure 197: Expanding Rules to Reveal Components**

Conditions		0	1.1	1.2	2.1	2.2

Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk

As we pointed out before, the outcome is the same for each sub-rule. Because of this, the sub-rules can be summarized as the general rules shown in column 1 of [Simple Rules for Profiling Insurance Policy Applicants](#). We also say that the two sub-rules "collapse" into the rules shown in column 1. The 'dash' symbol in the smoker value of column 1 indicates that the actual value of smoker does not matter to the execution of the rule – it will assign `riskRating` the value of `low` no matter what the smoker value is (as long as `age <= 55`, satisfying the first Condition). Looking at it a different way, only those rules with dashes in their columns have sub-rules, one for each value in the complete value set determined for that Condition row.

## The conflict checker

With our two rules expanded into four sub-rules as shown in [Expanding Rules to Reveal Components](#), most of the Cross Product is displayed for us. Click the **Check for Conflicts**  button in the toolbar.

**Figure 198: A Conflict Revealed by the Conflict Checker**

Conditions		0	1.1	1.2	2.1	2.2

Overrides						

  

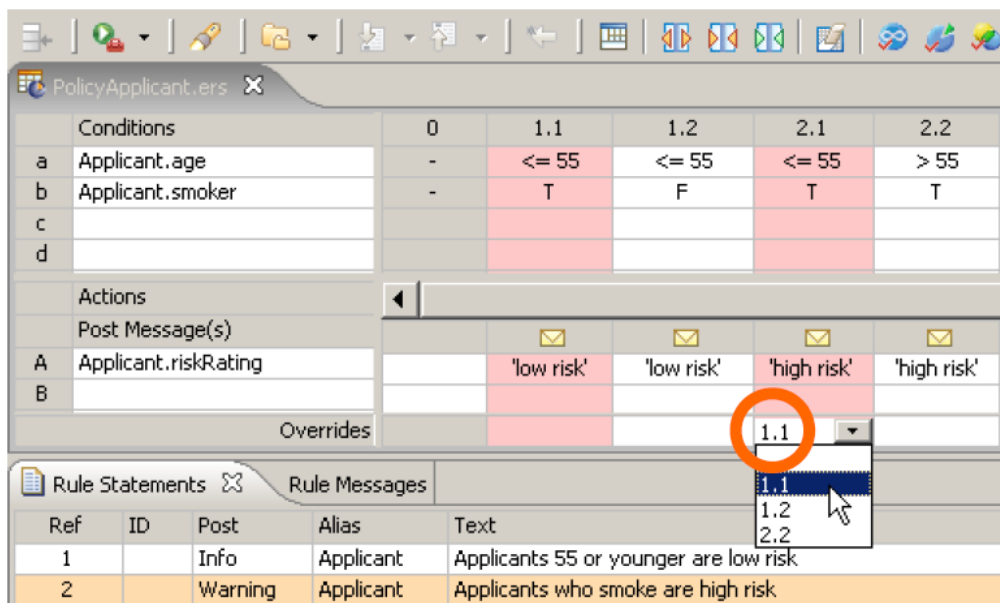

Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk

The mechanics of stepping through and resolving each conflict has been covered in detail in the *Corticon Studio - Basic Tutorial*. Here, our intent is to correlate the results of the automatic conflict check with the problems we identified first with the flowchart method, then later with test cases. Sub-rules 1.1 and 2.1, the sub-rules highlighted in pink and yellow in [Figure 198](#) on page 221, correspond to the intersection of column 1 and row 1 of [Rule 2 Expected Outcome](#) or test case #1 in [Test Cases Extracted from Cross Product](#). But note that Corticon Studio does not instruct the rule writer how to resolve the conflict – it simply alerts the rule writer to its presence. The rule writer, ideally someone who knows the business, must decide how to resolve the problem. The rule writer has two basic choices:

1. Change the Action(s) for one or both rules. We could change the Action in sub-rule 1.1 to match 2.1 or vice versa. Or we could introduce a new Action, say riskRating = medium, as the Action for both 1.1 and 2.1. If either method is used, the result will be that the Conditions and Actions of sub-rule 1.1 and 2.1 are *identical*. This removes the conflict, but introduces redundancy, which, while not a logical problem, can reduce processing performance in deployment. Removing redundancies in Rulesheets is discussed in the [Optimization](#) section of this chapter.
2. Use an **Override**. Think of an override as an exception. To override one rule with another means to instruct the Corticon Server to fire *only one* rule even when the Conditions of both rules are satisfied. Another way to think about overrides is to refer back to the discussion surrounding the flowchart in [Flowchart with 2 Dependent Rules](#). At the time, we were unclear which decision should execute first – no priority had been declared in our rules. But it made a big difference how we constructed our flowchart and what results it generated. To use an override here, we simply select the number of the sub-rule *to be overridden* from the drop-down box at the bottom of the column of the *overriding* sub-rule, as shown circled in the following figure. This is expressed simply as "sub-rule 2.1 overrides 1.1". It is incorrect to think of overrides as defining execution sequence. An override does not mean "fire rule 2.1 **then** fire rule 1.1." It means "fire rule 2.1 and **do not** fire rule 1.1".

Figure 199: Override Entered to Resolve Conflict

An override is essentially another business rule, which should to be expressed somewhere in the *Rule Statements* section of the Rulesheet. To express this override in plain English, the rule writer might choose to modify the rule statement for the *overridden* rule:

1. Applicants aged 55 or younger are assigned a low risk rating *unless* they smoke, in which case they are assigned a high risk rating.

This modification successfully expresses the effect of the override.

If ever in doubt as to whether you have successfully resolved a conflict, simply click the **Check for Conflicts** button again. The affected sub-rules should not highlight as you step through any remaining ambiguities. If all ambiguities have been resolved, you will see the following window:

**Figure 200: Conflict Resolution Complete**

## The completeness checker

While our rules are expanded, let's check for incompleteness. Again, the mechanics of this process are described in the *Corticon Studio tutorial: Basic Rule Modeling*. Our discussion here will be limited to correlating results with the previous manual methods of logical analysis.

Clicking the **Check for Completeness**  button, the message window is displayed:

**Figure 201: Completeness Check Message Window**

Clicking **OK** to dismiss the message window, we see that the Completeness Check has produced a new column (3), shaded in green:

**Figure 202: New Rule Added by Completeness Check**

The screenshot shows the Corticon Studio interface for a rule sheet named 'PolicyApplicant.ers'. The main area displays a table with conditions and actions. A new column, labeled '3' and shaded green, has been added to the conditions table. Below the conditions table is an 'Actions' section with a 'Post Message(s)' table. At the bottom, there are tabs for 'Rule Statements' and 'Rule Messages', with 'Rule Messages' currently selected, showing a list of messages.

Conditions	0	1.1	1.2	2.1	2.2	3
a Applicant.age	-	<= 55	<= 55	<= 55	> 55	> 55
b Applicant.smoker	-	T	F	T	T	F
c						
d						

Actions					
Post Message(s)					
A Applicant.riskRating		'low risk'	'low risk'	'high risk'	'high risk'
B					

Overrides				
			1.1	

Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk

This new rule, the combination of `age>55 AND smoker=false` corresponds to the intersection of column 2 and row 2 in [Rule 2 Expected Outcome](#) and test case #4 in [Test Cases Extracted from Cross Product](#). The Completeness Checker has discovered our missing rule! To do this, the Completeness Checker employs an algorithm which calculates all mathematical combinations of the Conditions' values (the Cross Product), and compares them to the combinations defined by the rule writer as other columns (other rules in the Rulesheet). If the comparison determines that some combinations are missing from the Rulesheet, these combinations are automatically added to the Rulesheet. As with the Conflict Check, the Action definitions of the new rules are left to the rule writer. The rule writer should also remember to enter new plain-language **Rule Statements** for the new columns so it is clear what logic is being modeled. The corresponding rule statement might look like this:

2. An applicant older than 55 who does not smoke is profiled as medium risk

## Automatically Determining the Complete Values Set

As values are manually entered into column cells in a Condition row, Corticon Studio automatically creates and updates a set of values, which for the given datatype of the Condition expression, is complete. This means that as you populate column cells, the list of values in the drop-down boxes you select from will grow and change.

In the drop-down box, you will see the list of values you have entered, plus null if the attribute or expression can have that value. But this list displayed in the drop-down is not the *complete* list – Corticon Studio maintains the complete list "under the covers" and only shows you the elements which you have manually inserted.

This automatically generated complete value list serves to feed the Completeness Checker with the information it needs to calculate the Cross Product and generate additional "green" columns. Without complete lists of possible values, the calculated Cross Product itself will be incomplete.

## Automatic Compression of the New Columns

Another important aspect of the Completeness Checker's operation is the automatic compression it performs on the resulting set of missing Conditions. As we see from the message displayed in [Completeness Check Message Window](#), the algorithm not only identifies the missing rules, but it also compresses them into *non-overlapping* columns. Two important points about this statement:

1. The compression performed by the Completeness Checker is a different kind of compression from that performed by the Compression Tool introduced in the [Optimization](#) section of this chapter. The optimized columns produced by the Completeness Check contain *no redundant sub-rules* (that's what non-overlapping means), whereas the Compression Tool will intentionally inject redundant sub-rules in order to create dashes wherever possible. This creates the optimal visual representation of the rules.
2. The compression performed here is designed to reduce the results set (which could be extremely large) into a manageable number while simultaneously introducing no ambiguities into the Rulesheet (which might arise due to redundant sub-rules being assigned different Actions).

## Limitations of the Completeness Checker

The Completeness Checker is powerful in its ability to discover missing combinations of Conditions from your Rulesheet. However, it is not smart enough to determine if these combinations make *business sense* or not. The example in the following figure shows two rules used in a health care scenario to screen for high-risk pregnancies:

**Figure 203: Example Prior to Completeness Check**

Conditions		0	1	2
a	Patient.gender		'female'	'female'
b	Patient.age		<= 40	> 40
c	Patient.pregnant		T	T
d				

Actions		0	1	2
A	Patient.riskFactor		'normal'	'elevated'
B				

Ref	ID	Post	Alias	Text
1		Info	Patient	Pregnant patients age 40 and younger are assigned a risk factor of normal risk
2		Warning	Patient	Pregnant patients older than 40 are assigned a risk factor of elevated risk

Now, we will click on the Completeness Checker:

**Figure 204: Example after Completeness Check**

Conditions		0	1	2	3	4
a	Patient.gender	-	'female'	'female'	<> 'female'	'female'
b	Patient.age	-	<= 40	> 40	-	-
c	Patient.pregnant	-	T	T	-	F
d						

Actions		0	1	2	3	4
A	Patient.riskFactor		'normal'	'elevated'		
B						

Ref	ID	Post	Alias	Text
1		Info	Patient	Pregnant patients age 40 and younger are assigned a risk factor of normal risk
2		Warning	Patient	Pregnant patients older than 40 are assigned a risk factor of elevated risk

**Corticon Business Rules Modeling Studio**

Completeness check has added 6 missing scenarios which have been automatically compressed in to 2 non-overlapping columns.

OK

Notice that columns 3-4 have been automatically added to the Rulesheet. But also notice that column 3 contains an unusual Condition: `gender <> female`. Because the other two Conditions in column 3 have dash values, we know it contains component or sub-rules. By double-clicking on column 3's header, its sub-rules are revealed:

**Figure 205: Non-Female Sub-Rules Revealed**

3.1	3.2	3.3	3.4
<> 'female'	<> 'female'	<> 'female'	<> 'female'
<= 40	<= 40	> 40	> 40
T	F	T	F

Because our Rulesheet is intended to identify high-risk pregnancies, it would not seem necessary to evaluate non-female (i.e., male) patients at all. And if male patients are evaluated, then we can say with some certainty that the scenarios described by sub-rules 3.1 and 3.3 – those scenarios containing pregnant males – are truly unnecessary. While these combinations may be members of the Cross Product, they are clearly not combinations that can occur in real life. If other rules in an application prevent combinations like this from occurring, then sub-rules 3.1 and 3.3 may also be unnecessary here. On the other hand, if no other rules catch this faulty combination earlier, then we may want to use this opportunity to raise an error message or take some other action that prompts a re-examination of the input data.

## Renumbering Rules

Continuing with the previous pregnancy example, let's assume that we agree that sub-rules 3.1 and 3.3 are impossible, and so may be safely ignored. However, we decide to keep sub-rules 3.2 and 3.4 and assign Actions to them. For this example, we will just post violation messages to them.

However, when we try to enter Rule Statements for sub-rules 3.2 and 3.4, we discover that Rule Statements can only be entered for general rules (whole-numbered columns), not sub-rules. To convert column 3, with its four sub-rules, into four whole-numbered general rules, select **Rulesheet > Rule Column(s) > Renumber Rules** from the **Studio** menubar.

**Figure 206: Sub-Rules Renumbered and Converted to General Rules**

Conditions		0	1	2	3	4	5	6	7
a	Patient.gender	-	'female'	'female'	<> 'female'	<> 'female'	<> 'female'	<> 'female'	'female'
b	Patient.age	-	<= 40	> 40	<= 40	<= 40	> 40	> 40	-
c	Patient.pregnant	-	T	T	T	F	T	F	F
d									
Actions									
Post Message(s)									
A	Patient.riskFactor		normal	elevated					
B									
Overrides									
Rule Statements									
Rule Messages									
Ref	ID	Post	Alias	Text					
1		Info	Patient	Pregnant patients age 40 and younger are assigned a risk factor of normal risk					
2		Warning	Patient	Pregnant patients older than 40 are assigned a risk factor of elevated risk					

Now that the columns have been renumbered, Rule Statements may be assigned to columns 4 and 6, and columns 3 and 5 can be deleted or disabled (if you want to do so).

When impossible or useless rules are created by the Completeness Checker, we recommend disabling the rule columns rather than deleting them. When disabled, the columns remain visible to all modelers, eliminating any surprise (and shock) when future modelers apply the Completeness Check and discover missing rules that you had already found and deleted. And if you disable the columns, be sure to include a Rule Statement that explains why. See the following figure for an example of a fully complete and well-documented Rulesheet

**Figure 207: Final Rulesheet with impossible rules disabled**

The screenshot shows the 'CompletenessCheckerLimitations.ers' application. The main window displays a rulesheet with columns for Conditions (a, b, c, d) and Actions (A, B). The 'Conditions' section has columns 0 through 7. Columns 1, 2, 3, 4, 5, 6, and 7 are marked as disabled with a yellow 'X' icon. The 'Actions' section has columns 0 through 7. Columns 1, 2, 3, 4, 5, 6, and 7 are marked as disabled with a yellow 'X' icon. Below the rulesheet, the 'Rule Statements' tab is active, showing a list of rule messages with columns for Ref, ID, Post, Alias, and Text.

Conditions	0	1	2	3	4	5	6	7
a Patient.gender	-	'female'	'female'	<> 'female'	<> 'female'	<> 'female'	<> 'female'	'female'
b Patient.age	-	<= 40	> 40	<= 40	<= 40	> 40	> 40	-
c Patient.pregnant	-	T	T	T	F	T	F	F
d								

Ref	ID	Post	Alias	Text
1		Info	Patient	Pregnant patients age 40 and younger are assigned a risk factor of normal risk
2		Warning	Patient	Pregnant patients older than 40 are assigned a risk factor of elevated risk
{ 4 , 6 }		Warning	Patient	Non-pregnant, non-females not considered by this decision
{ 3 , 5 }		Violation	Patient	Pregnant non-females are not possible; these rules have been disabled
7		Warning	Patient	Non-pregnant females not considered by this decision

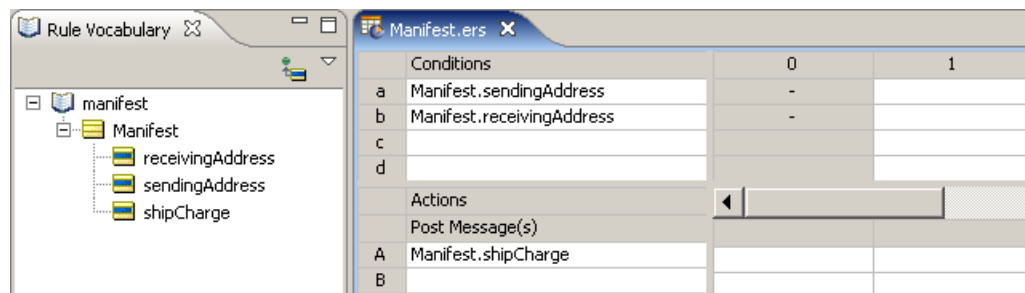

## Letting the expansion tool work for you: tabular rules

Business rules, especially those found in operational manuals or procedures, often take the form of tables. Take for example the following table that generates shipping charges between two geographic zones:

Matrix to Calculate Shipping Charges per Pound					
From/To	zone 1	zone 2	zone 3	zone 4	zone 5
zone 1	\$0.25	\$0.35	\$0.45	\$0.55	\$0.65
zone 2	\$0.35	\$0.25	\$0.35	\$0.45	\$0.55
zone 3	\$0.45	\$0.35	\$0.25	\$0.35	\$0.45
zone 4	\$0.55	\$0.45	\$0.35	\$0.25	\$0.35
zone 5	\$0.65	\$0.55	\$0.45	\$0.35	\$0.25

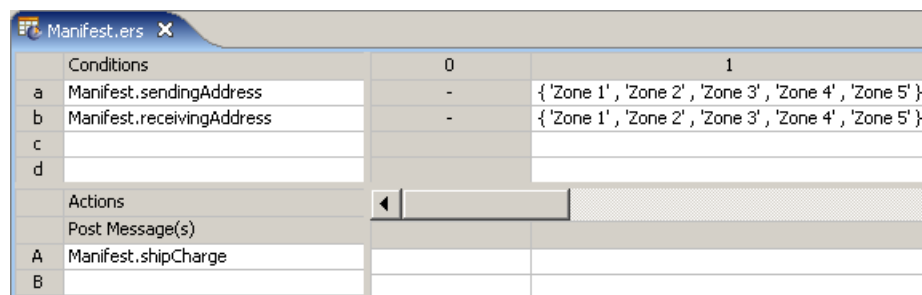

In the following figure, we have built a simple Vocabulary with which to implement these rules. Because each cell in the table represents a single rule, our Rulesheet will contain 25 columns (the Cross Product equals 5x5 or 25).

**Figure 208: Vocabulary and Rulesheet to Implement Matrix**

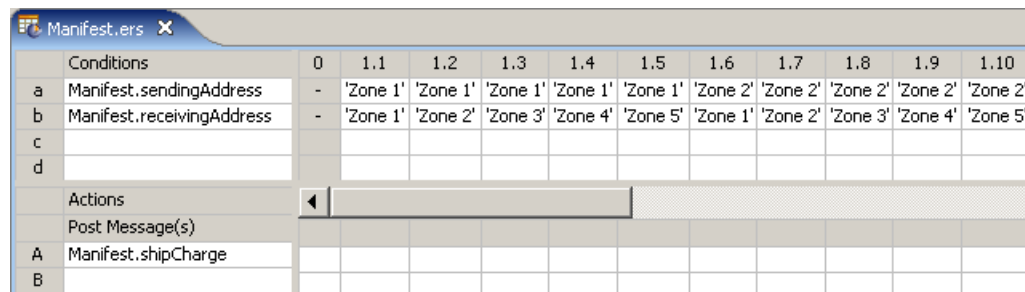

Rather than manually create all 25 combinations (and risk making a mistake), you can use the Expansion Tool to help you do it. This is a three-step process. Step 1 consists of entering the full range of values found in the table in the Conditions cells, as shown:

**Figure 209: Rulesheet with Conditions Automatically Populated**

Now, use the Expansion Tool to expand column 1 into 25 non-overlapping columns. We now see the 25 sub-rules of column 1 (only the first ten sub-rules are shown in the following figure due to page width limitations in this document):

**Figure 210: Rule 1 Expanded to Show Sub-Rules**

Each sub-rule represents a single cell in the original table. Now, select the appropriate value of `shipCharge` in the **Actions** section of each sub-rule as shown:

**Figure 211: Rulesheet with Actions Populated**

Conditions		0	1.1	1.2	1.3	1.4	1.5	1.6	1.7	1.8	1.9	1.10
a	Manifest.sendingAddress	-	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 2'	'Zone 2'	'Zone 2'	'Zone 2'	'Zone 2'
b	Manifest.receivingAddress	-	'Zone 1'	'Zone 2'	'Zone 3'	'Zone 4'	'Zone 5'	'Zone 1'	'Zone 2'	'Zone 3'	'Zone 4'	'Zone 5'
c												
d												
Actions												
Post Message(s)												
A	Manifest.shipCharge		0.25	0.35	0.45	0.55	0.65	0.35	0.25	0.35	0.45	0.55
B												

In step 3, shown in the following figure, we **renumber** the sub-rules to arrive at the final Rulesheet with 25 general rules, each of which may now be assigned a Rule Statement.

**Figure 212: Rulesheet with Renumbered Rules**

Conditions		0	1	2	3	4	5	6	7	8	9	10
a	Manifest.sendingAddress	-	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 2'	'Zone 2'	'Zone 2'	'Zone 2'	'Zone 2'
b	Manifest.receivingAddress	-	'Zone 1'	'Zone 2'	'Zone 3'	'Zone 4'	'Zone 5'	'Zone 1'	'Zone 2'	'Zone 3'	'Zone 4'	'Zone 5'
c												
d												
Actions												
Post Message(s)												
A	Manifest.shipCharge		0.25	0.35	0.45	0.55	0.65	0.35	0.25	0.35	0.45	0.55
B												

We will revisit this example in the [Optimization](#) section.

## Memory management

As you might suspect, the Completeness Checker and Expansion algorithms are memory-intensive, especially as Rulesheets become very large. If Corticon Studio runs low on memory, refer to the *Corticon Studio Installation Guide*, "Changing Corticon Studio Memory Allocation" section, for details on increasing Corticon Studio's memory allotment.

## Logical loop detection

Corticon Studio has the ability to both detect and control rule looping. This is important because loops are sometimes inadvertently created during rule implementation. Other times, looping is intentionally introduced to accomplish specific purposes. Both scenarios are discussed in the chapter [Rule Dependency: Chaining and Looping](#).

# Optimizing rulesheets

## The compress tool

Corticon Studio helps improve performance by removing redundancies within Rulesheets. There are two types of redundancies the **Compress Tool**  detects and removes:

1. Rule or sub-rule duplication. The Compress Tool will search a Rulesheet for duplicate columns (including sub-rules that may not be visible unless the rule columns are expanded), and delete extra copies. Picking up where we left off in [New Rule Added by Completeness Check](#), let's add another rule (column #4), as shown in the following figure:

Figure 213: New Rule (#4) Added

PolicyApplicant.ers		0	1	2	3	4
Conditions						
a	Applicant.age	-	<= 55	-	> 55	<= 55
b	Applicant.smoker	-	-	T	F	F
c						
d						
Actions						
Post Message(s)						
A	Applicant.riskRating		'low risk'	'high risk'	'medium risk'	'low risk'
B						
Overrides						

Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk
3		Info	Applicant	Applicants 55 or older who do not smoke are medium risk
4		Info	Applicant	Applicants 55 or younger who do not smoke are low risk

While these 4 rules use only 2 Conditions and take just 2 Actions (an assignment to `riskRating` and a posted message), they already contain a redundancy problem. Using the **Expand Tool**  this redundancy is visible in the following figure:

Figure 214: Redundancy Problem Exposed

PolicyApplicant.ers		0	1.1	1.2	2.1	2.2	3	4
Conditions								
a	Applicant.age	-	<= 55	<= 55	<= 55	> 55	> 55	<= 55
b	Applicant.smoker	-	T	F	T	T	F	F
c								
d								
Actions								
Post Message(s)								
A	Applicant.riskRating		'low risk'	'low risk'	'high risk'	'high risk'	'medium risk'	'low risk'
B								
Overrides					1.1			

Ref	ID	Post	Alias	Text
1		Info	Applicant	Applicants 55 or younger are low risk
2		Warning	Applicant	Applicants who smoke are high risk
3		Info	Applicant	Applicants 55 or older who do not smoke are medium risk
4		Info	Applicant	Applicants 55 or younger who do not smoke are low risk

Clicking on the **Compress Tool**  has the effect shown in the following figure:

**Figure 215: Rulesheet After Compression**

PolicyApplicant.ers		0	1	2	3
Conditions					
a	Applicant.age	-	<= 55	-	> 55
b	Applicant.smoker	-	-	T	F
c					
d					
Actions					
Post Message(s)					
A	Applicant.riskRating		'low risk'	'high risk'	'medium risk'
B					
Overrides					1.1
Rule Statements					
Ref	ID	Post	Alias	Text	
1		Info	Applicant	Applicants 55 or younger are low risk	
1		Warning	Applicant	Applicants who smoke are high risk	
3		Info	Applicant	Applicants 55 or older who do not smoke are medium risk	
3		Info	Applicant	Applicants 55 or younger who do not smoke are low risk	

Looking at the compressed Rulesheet in this figure, we see that column #4 has disappeared entirely. More accurately, the Compress Tool determined that column 4 was a duplicate of one of the sub-rules in column 1 (1.2) and simply removed it. Looking at the Rule Statement section, we see that the rule statement for rule 4 has been renumbered to match the surviving rule.

Compression does not, however, alter the *text* of the rule statement; that task is left to the rule writer.

It is important to note that the compression does not alter the Rulesheet's logic; it simply affects the way the rules **appear** in the Rulesheet – the number of columns, Values sets in the columns, and such. Compression also streamlines rule execution by ensuring that no rules are processed more than necessary.

- Combining Values sets to simplify and shorten Rulesheets. Recall our shipping charge example. By using the Compress Tool, Rulesheet columns are combined wherever possible by creating Values sets in Condition cells. For example, rule 6 in the figure **Compressed Shipping Charge Rulesheet** (highlighted below) is the combination of rule 6 and 8 from [Rulesheet with Renumbered Rules](#).

**Figure 216: Compressed Shipping Charge Rulesheet**

Manifest.ers		0	1	2	3	4	5	6
Conditions								
a	Manifest.sendingAddress	-	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 1'	'Zone 2'
b	Manifest.receivingAddress	-	'Zone 1'	'Zone 2'	'Zone 3'	'Zone 4'	'Zone 5'	{ 'Zone 1', 'Zone 3' }
c								
d								
Actions								
Post Message(s)								
A	Manifest.shipCharge		0.25	0.35	0.45	0.55	0.65	0.35

Value sets in Condition cells are equivalent to the logical operator **OR**. Rule 6 therefore reads:

6. A manifest with a Zone 2 sending address **AND** a Zone 1 **OR** Zone 3 receiving address costs \$0.35 per pound to ship.

In deployment, The Server will execute this new rule 6 faster than the previous rule 6 and 8 together.

## Producing characteristic Rulesheet patterns

Because Corticon Studio is a visual environment, patterns often appear in the Rulesheet that provide insight into the decision logic. Once a rule writer recognizes and understands what these patterns mean, he or she can often accelerate rule modeling in the Rulesheet. The Compression Tool is designed to reproduce Rulesheet patterns in some common cases.

For example, take the following rule statement:

1. An aircraft with max cargo volume greater than 300 AND max cargo weight greater than 200,000 AND tail number of N123UA must be a 747.
2. Otherwise it must be a DC-10.

Applying some of the techniques from this manual, we might implement rule 1 as:

**Figure 217: Implementing the 747 Rule**

Conditions		0	1	2
a	Aircraft.maxCargoVolume	-	> 300	
b	Aircraft.maxCargoWeight	-	> 200000	
c	Aircraft.tailNumber	-	'N123UA'	
d				
Actions				
Post Message(s)				
A	Aircraft.aircraftType		'747'	
B				
Overrides				

Ref	ID	Post	Alias	Text
1		Info	Aircraft	An aircraft with max cargo volume greater than 300 and max cargo weight of greater than 200,000 pounds and a tail number of N123UA is assigned to a 747.

Now, letting the Completeness Checker populate the missing columns:

**Figure 218: Remaining Columns Produced by the Completeness Checker**

The screenshot shows the Corticon Business Rules Modeling Studio interface. The 'Rule Messages' tab is active, displaying a message: "Completeness check has added 26 missing scenarios which have been automatically compressed in to 3 non-overlapping columns." The 'Rule Statements' section shows a table with columns 0 through 5. The 'Rule Messages' section also shows a table with columns 0 through 5.

Conditions	0	1	2	3	4	5
a Aircraft.maxCargoVolume	-	> 300	> 300	> 300	{ <= 300 , null }	
b Aircraft.maxCargoWeight	-	> 200000	> 200000	{ <= 200000 , n...	-	
c Aircraft.tailNumber	-	'N123UA'	{ <> 'N123UA' , ...	-	-	
d						

The 'Rule Messages' section shows a table with columns 0 through 5.

Ref	ID	Post	Alias	Text	Rule Name	Rule Link
1		Info	Aircraft	An aircraft with max cargo volume greater than 300 and max cargo weight of greater than 200,000 pounds and a tail number of N123UA is assigned to a 747.		

To remind you of the underlying Cross Product used by the Completeness Checker, we will **Expand** the Rulesheet momentarily and examine the sub-rules present:

**Figure 219: Underlying Sub-Rules Produced by the Completeness Checker**

0	1	2.1	2.2	3.1	3.2	3.3	3.4	3.5
-	> 300	> 300	> 300	> 300	> 300	> 300	> 300	> 300
-	> 200000	> 200000	> 200000	<= 200000	<= 200000	<= 200000	null	null
-	'N123UA'	<> 'N123UA'	null	<> 'N123UA'	'N123UA'	null	<> 'N123UA'	'N123UA'

A total of 26 new columns (counting both rules and sub-rules) have been created – exactly what we expect and what the **Completeness Check** message window states.

**Note:** Three Conditions each with three members in their Values sets yields a Cross Product of 27 combinations (3\*3\*3 or 3 cubed). Subtracting the combination already present in column 1, we expect 26 new columns to be added.

Now, **Compress**  the Rulesheet and fill in the Actions for the new columns as shown in [Missing Rules with Actions Assigned](#):

**Figure 220: Missing Rules with Actions Assigned**

CargoWithTailNumber.ers		0	1	2	3	4
a	Aircraft.maxCargoVolume	-	> 300	-	-	{ <= 300 , null }
b	Aircraft.maxCargoWeight	-	> 200000	-	{ <= 200000 , null }	-
c	Aircraft.tailNumber	-	'N123UA'	{ <> 'N123UA' , null }	-	-
d						
Actions						
Post Message(s)						
A	Aircraft.aircraftType		'747'	'DC-10'	'DC-10'	'DC-10'

Because the added rules are non-overlapping, we can be sure they won't introduce any ambiguities into the Rulesheet. To prove this, select the **Conflict Checker** 

**Figure 221: Proof that no New Conflicts have been Introduced by the Completeness Check**

The screenshot shows the Corticon Business Rules Modeling Studio interface. A modal dialog box is displayed in the center with the title "Corticon Business Rules Modeling Studio" and a close button. The dialog contains an information icon and the text "No conflicts detected", with an "OK" button at the bottom. In the background, a table is visible with columns labeled 0, 1, 2, 3, and 4. The table has two sections: "Conditions" and "Actions".

	0	1	2	3	4
<b>Conditions</b>					
a	Aircraft.maxCargoVolume			-	{ <= 300 , null }
b	Aircraft.maxCargoWeight			200000 , null }	-
c	Aircraft.tailNumber			-	-
d					
<b>Actions</b>					
Post Message(s)					
A	Aircraft.aircraftType			'DC-10'	'DC-10'

This pattern tells us that the only case where the aircraft type is a 747 is when max cargo volume is greater than 300 **AND** max cargo weight is greater than 200,000 **AND** tail number is N123UA. This rule is expressed in column 1. In all other cases, specifically where max cargo volume is 300 or less **OR** max cargo weight is 200,000 or less **OR** tail number is something other than N123UA will the aircraft type be a DC-10 (or any of the values are null). These rules are expressed in columns 2, 3 and 4, respectively.

The characteristic diagonal line of Condition values in columns 2-4, surrounded by dashes indicates a classic **OR** relationship between the 3 Conditions in these columns. The Compression algorithm was designed to produce this characteristic pattern whenever the underlying rule logic is present. It helps the rule writer to better "see" how the rules relate to each other.

## Compression creates sub-rule redundancy

Compressing our example into a recognizable pattern, however, has an interesting side-effect - we have also introduced more sub-rules than were initially present. To see this, simply **Expand**  the Rulesheet as shown:

**Figure 222: Expanding Rules *Following* Compression**

[illegible]

You may be surprised to see a total of 54 sub-rules (columns) displayed (in the figure above) instead of the 26 we had prior to compression. Look closely at the 54 columns and you will see several instances of sub-rule redundancy – of the 18 sub-rules within original columns 2, 3 and 4, almost half are redundant (for example, sub-rules 2.1, 3.1 and 4.1, shown in the figure above, are identical). What happened?

## Effect of compression on Corticon Server performance

Why does Corticon Studio have what amounts to two different kinds of compression – one performed by the Completeness Checker and another performed by the Compression Tool? It is because each has a different role during the rule modeling process. The type of compression performed during a Completeness Check is designed to reduce a (potentially) very large set of missing rules into the smallest possible set of non-overlapping columns. This allows the rule writer to assign Actions to the missing rules without worrying about accidentally introducing ambiguities.

On the other hand, the compression performed by the Compression Tool is designed to reduce the number of rules into the smallest set of general rules (columns with dashes), even if the total number of sub-rules is larger than that produced by the Completeness Checker. This is important for three reasons:

1. The Compression Tool preserves or reproduces key patterns familiar and meaningful to the rule modeler
2. The Compression Tool, by reducing a Rulesheet to the smallest number of columns, optimizes the executable code produced by Corticon Server's on-the-fly compiler. Smaller Rulesheets (lower column count) result in faster Corticon Server performance.
3. The Compression Tool, by reducing columns to their most general state (the most dashes), improves Corticon Server performance by allowing it to ignore all Conditions with dash values. This means that when the rule in column 3 of [Missing Rules with Actions Assigned](#) is evaluated by Corticon Server, only the max cargo weight Condition is considered – the other two Conditions are ignored entirely because they contain dash values. When rule 3 of [Missing Rules with Actions Assigned](#) is evaluated after the **Completeness Check** is applied but *before* the **Compression Tool**, however, both max cargo weight and volume Conditions are considered, which takes slightly more time. So even though both Rulesheets have the same number of columns (four), the Rulesheet with more generalized rules (more dashes - [Missing Rules with Actions Assigned](#)) will execute faster because the engine is doing less work.

## Test yourself - questions – logical analysis and optimization

---

**Note:** Try this test, and then go to **Answers:** [Logical analysis & optimization](#) on page 289 to correct yourself.

---

1. What does it mean for two rules to be ambiguous?
2. What does it mean for a Rulesheet to be complete?
3. Are all ambiguous rules wrong, and must all ambiguities be resolved before deployment? Why or why not?
4. Are all incomplete Rulesheets wrong, and must all incompletenesses be resolved before deployment? Why or why not?

## 5. Match the Corticon Studio tool name with its toolbar icon

Conflict Checker	
Compression Tool	
Expansion Tool	
Collapse Tool	
Conflict Filter	
Completeness Checker	

6. Explain the different ways in which an Ambiguity/Conflict between two rules can be resolved.
7. True or False. Defining an override enforces a specific execution sequence of the two ambiguous rules
8. True or False. A Conditions row with an incomplete values set will always result in an incomplete Rulesheet.
9. If a Rulesheet is incomplete due to an incomplete values set, will the Completeness Checker detect the problem? Why or why not?
10. Can a rule column define more than one override?
11. If rule 1 overrides rule 2, and rule 2 overrides rule 3, does rule 1 automatically override rule 3?
12. Are rules created by the Completeness Checker always legitimate?
13. In a rule column, what does a dash (-) character mean?
14. True or False. The Expansion Tool permanently changes the rule models in a Rulesheet. If false, how can it be reversed?
15. True or False. The Compression Tool permanently changes the rule models in a Rulesheet. If false, how can it be reversed?
16. If a rule has 3 condition rows, and each condition row has a Values set with 4 elements, what is the size of the Cross Product?
17. In above question, is it necessary to assign actions for every set of conditions (i.e., for every column)?
18. If you do not want to assign actions for every column, what can be done to/with these columns?
19. Which Corticon Studio tool helps to improve Rulesheet performance?

Expansion Tool	Compression Tool	Completeness Checker	Collapse Tool	Squeeze Tool
----------------	------------------	----------------------	---------------	--------------

20. How is the compression performed by the Completeness Checker different from that performed by the Compression Tool?
21. What's wrong with using databases of test data to discover Rulesheet incompleteness?

- 22. If you expand a rule column and change the Actions for one of the sub-rules, what will Corticon Studio force you to do before saving the changes?
- 23. What does it mean for one rule to subsume another?

## Ruleflow versioning & effective dating

---

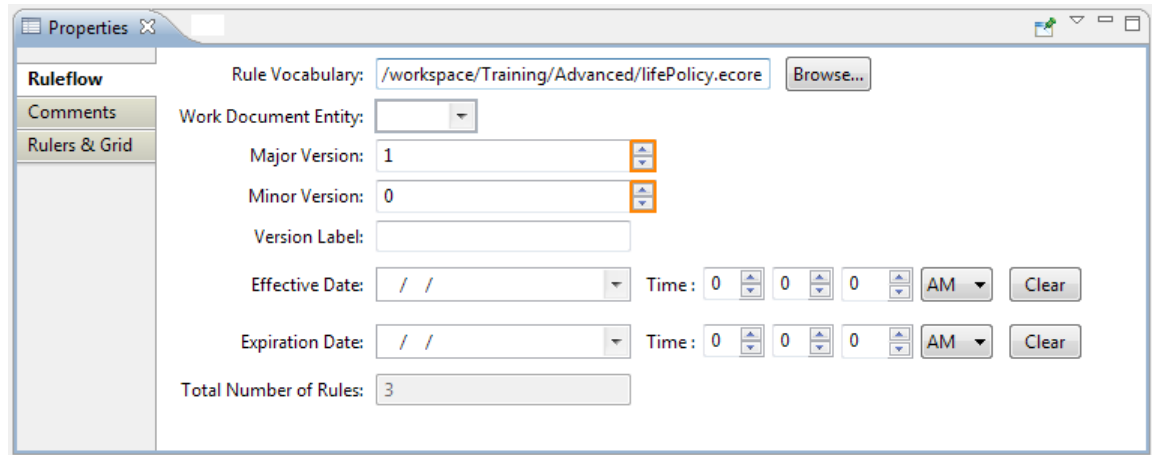

For details, see the following topics:

- [Setting a Ruleflow version](#)
- [Major and minor versions](#)
- [Setting effective and expiration dates](#)
- [Test yourself - questions – ruleflow versioning & effective dating](#)

## Setting a Ruleflow version

Major and minor version numbers for Ruleflows are optional. They can be assigned by selecting the menu command **Ruleflow > Properties**, and then clicking on the buttons on the **Major Version** and **Minor Version** lines, as highlighted:

**Figure 223: Assigning a Version Number to a Ruleflow**

When you use different Version numbers to describe identically named Ruleflows, the Corticon Server keeps them distinguished in its memory, so it can respond correctly to requests for a specified version. In other words, an application or process can use (or "call") different versions of the same Ruleflow depending on certain criteria. The details of how this works at the Server level are discussed in the topics at *"Decision Service versioning and effective dating" in the Integration & Deployment Guide*.

A plain-text description of this version can be added in the **Comments** tab. Version numbers can be set higher at anytime, but cannot be set lower.

## Major and minor versions

Minor and Major version designations are arbitrary and may be adapted to fit the version naming conventions used in different environments. As an example, Ruleflow minor versions may be incremented whenever a component Rulesheet is modified. Major Ruleflow versions may be incremented when more substantial changes are made to it, such as adding, replacing, or removing a Rulesheet from the Ruleflow.

Version numbers can be incremented, but not decremented.

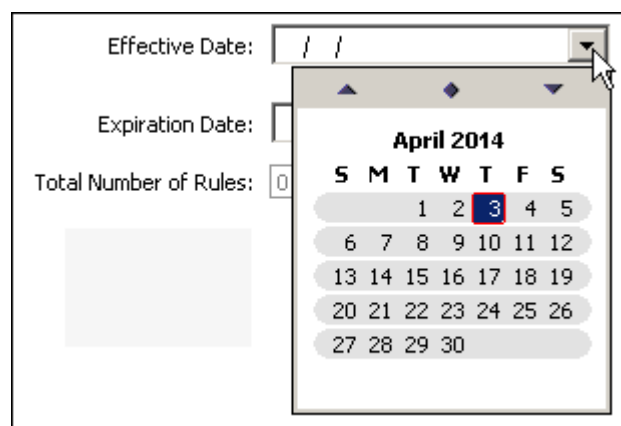

For details on how to invoke a Ruleflow by version number, see the topic *"Decision Service versioning and effective dating" in the Integration & Deployment Guide*.

## Setting effective and expiration dates

Effective and Expiration dateTimes are optional for Ruleflows and can be assigned singly or in pairs. When we use different Effective and Expiration dateTimes to describe identically named Ruleflows, the Corticon Server keeps them straight in memory, and responds correctly to requests for the different dates. In other words, an application or process can use different versions of the same Ruleflow depending on dateTime criteria. The details of how this works at the Corticon Server level is technical in nature and is described in the *Server Integration & Deployment Guide*.

Effective and Expiration Dates may be assigned using the same window as above. Clicking on the **Effective Date** or **Expiration Date** drop-down displays a calendar and clock interface, as shown below:

**Figure 224: Setting Effective and Expiration Dates**

## Test yourself - questions – ruleflow versioning & effective dating

---

**Note:** Try this test, and then go to **Answers:** [Ruleflow versioning and effective dating](#) on page 290 to correct yourself.

---

1. True or False. If a Ruleflow has an Effective date, it must also have an Expiration date.
2. True or False. If a Ruleflow has an Expiration date, it must also have an Effective date.
3. True or False. Ruleflow Version numbers are mandatory
4. Which Corticon Studio menu contains the Ruleflow Properties settings?
5. True or False. A Ruleflow Minor or Major Version number may be raised or lowered.
6. True or False. Ruleflow Effective and Expiration dates are mandatory.

---

## Localizing Corticon Studio

---

Localizing your rule modeling and processing environment involves three related functions:

- Displaying the Studio **program** in your locale of choice. This means switching the Corticon Studio user interface (menus, operators, system messages, etc.) to a new language. See *"Enabling Studio internationalization" in the Studio Installation Guide*.
- Displaying your Studio **assets** in your locale of choice. This means switching your Vocabularies, Rulesheets, Ruleflows, and Ruletests to a new language. This part is described here.
- Requests submitted to a Corticon Server can specify an execution property that indicates the **locale of the incoming payload** so that the server can transform the payload's decimal and date values to the decimal delimiter and month literal names of the server, run the rules, and return the output formatted to the submitter's preference. See *"Handling requests and replies across locales" in the Server Integration and Deployment Guide*.

For details, see the following topics:

- [Localizing the Vocabulary](#)
- [Localizing the Rulesheet](#)

## Localizing the Vocabulary

A Vocabulary can be localized into several different languages. If a Vocabulary includes multiple locale information, then Corticon Studio displays the locale corresponding to the operating system's current locale.

To localize a Vocabulary, select **Vocabulary>Localize...** from Corticon Studio's menubar as shown below:

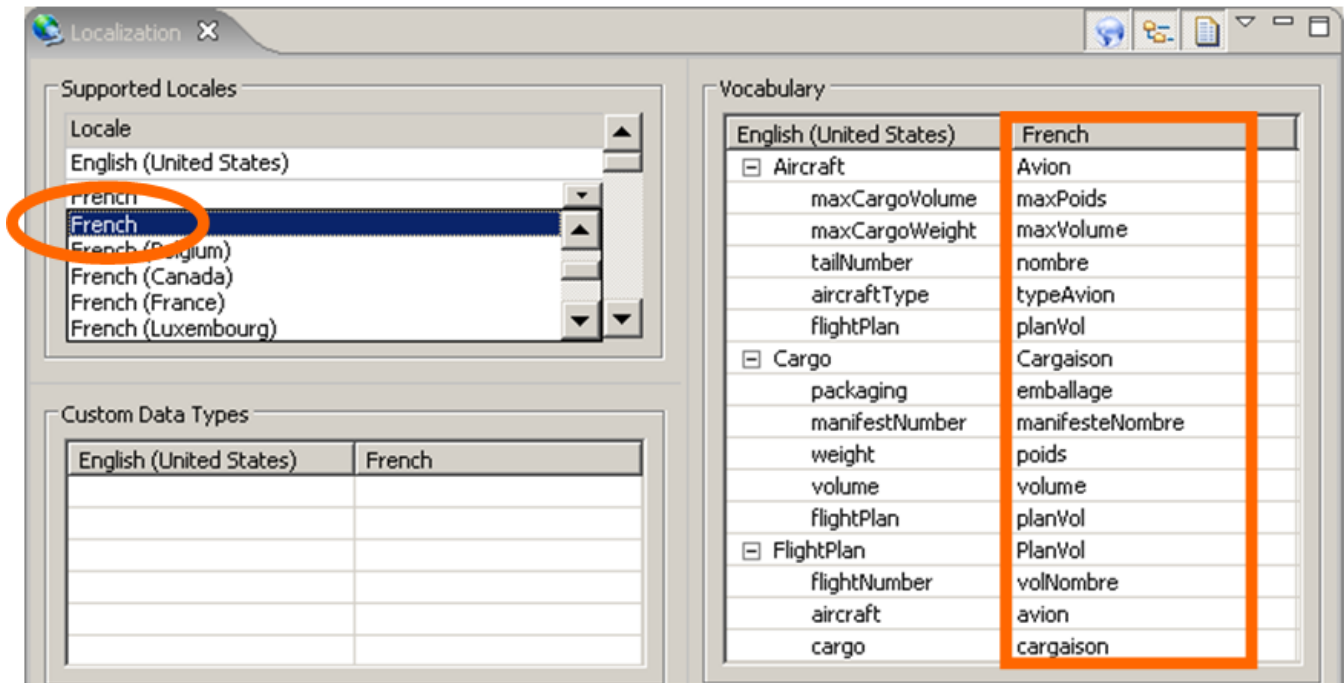

**Figure 225: Localize a Vocabulary**

Corticon Studio displays the Vocabulary Localization window as shown below.

Notice that we've selected French in the second line of the **Supported Locales** pane, circled below in orange. This choice causes a second column to appear to the right in the **Vocabulary** pane (shown below in an orange rectangle).

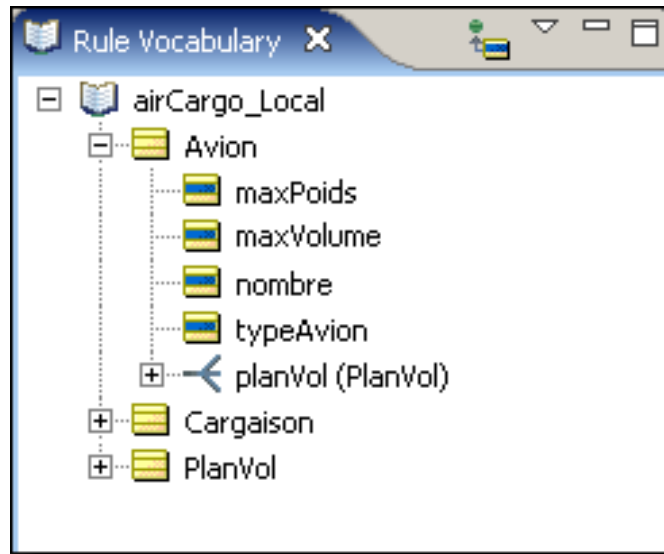

**Figure 226: Selecting and populating a second locale**

In the **French** column, we must manually add French translations for each Vocabulary term, including association role names. These translated terms must be unique from the English or other base version shown in the left-hand column.

With a localized Vocabulary, now switch your operating system to French locale. Different OS's have different methods for switching locales - consult your OS help or documentation for assistance.

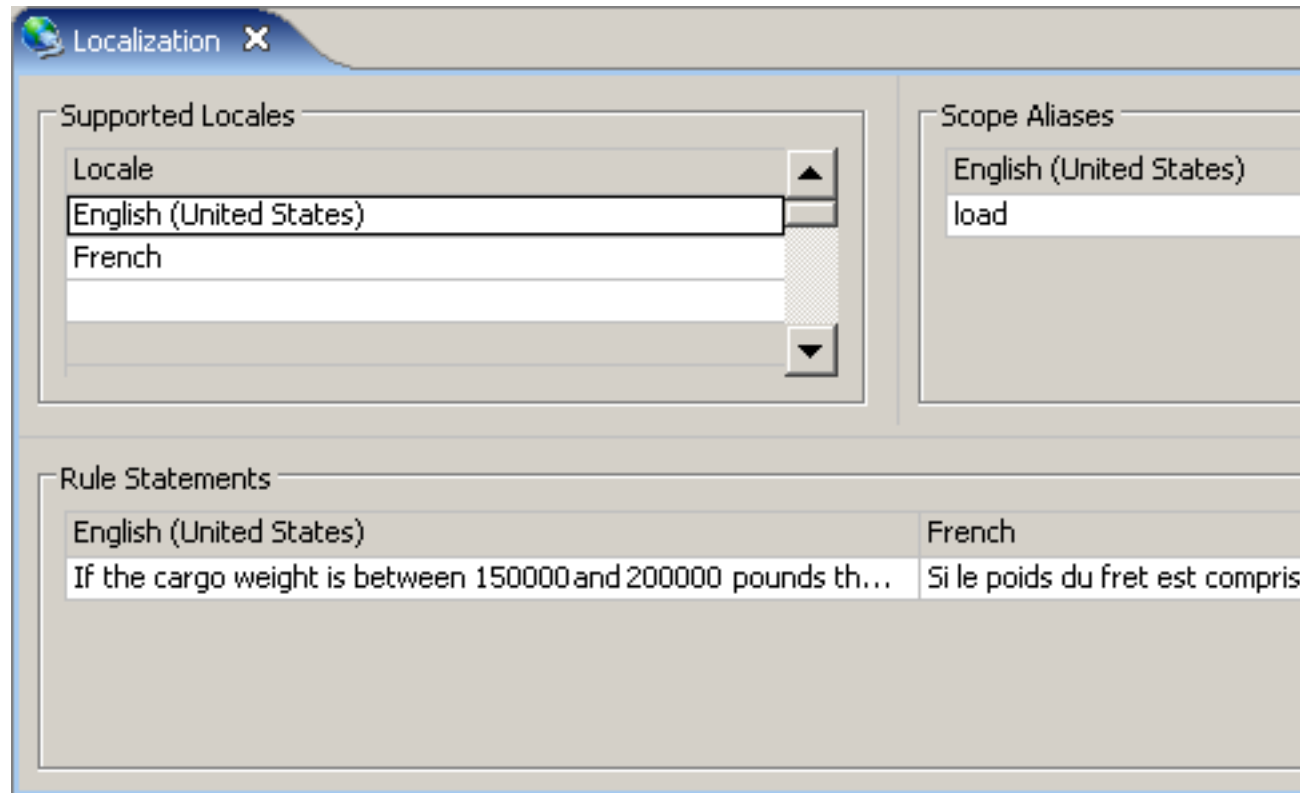

**Figure 227: A Vocabulary displaying its French translation**

## Localizing the Rulesheet

When you create a new Rulesheet or Ruletest using a localized Vocabulary, those assets will be localized too. The **Rulesheet >Localize...** menu selection allows you to further localize the Rulesheet by translating Scope aliases and Rule Statements, as shown below:

**Figure 228: A Rulesheet displaying its French translation**

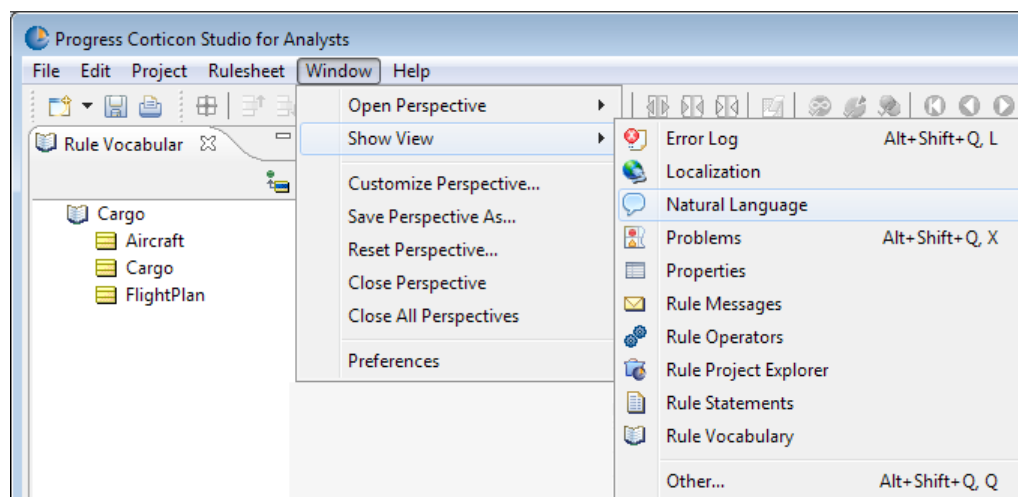

## Working with rules in natural language

Progress Corticon lets you use Natural Language (NL) words, phrases, and sentences for use as substitute terms in Rulesheet Conditions and Actions.

Open the Natural Language window by choosing the menu command **Window>Show View>Natural Language**.

**Figure 229: Opening the Natural Language view for a Rulesheet**

You could also right-click on the Rulesheet to drop down a menu with the **Natural Language** command.

**Note:** If you do not see the **Natural Language** command listed, you may need to **Reset Perspective** first. This typically only happens if you are upgrading from an earlier version of Corticon Studio.

The Natural Language view displays at the top of the Rulesheet in Corticon Studio:

**Figure 230: The Natural Language View**

Natural Language	
Condition Expression	English (United States)
a	Cargo.weight
b	Cargo.volume
c	Cargo.needsRefrigeration
Action Expression	English (United States)
A	Cargo.container

If you have other Locales enabled (see [Localization](#) chapter for more details), then the Natural Language window will include columns for other languages besides English. This allows you to define Natural Language text for those locales, too.

A populated Natural Language window is shown below. Notice that we've tried to be as clear and descriptive as possible, including the words *If* in Conditions and *Then* in Actions. We've also used ... to indicate that the expression continues in the column cells to the right. Your use of natural language may vary, but we recommend adopting a consistent, clear style.

**Figure 231: Populating the Natural Language Window populated with natural language text**

Natural Language	
Condition Expression	English (United States)
a	Cargo.weight If the Cargo's weight is...
b	Cargo.volume If the Cargo's volume is...
c	Cargo.needsRefrigeration If the Cargo needs refrigeration...
Action Expression	English (United States)
A	Cargo.container Then the type of container required by this Cargo is...

When your natural language expressions are defined, view these entries in place of the standard Condition and Action expressions in the Rulesheet as follows:

1. Close the **Natural Language** view by clicking its **X**.
2. Click the **Natural Language: On** menu button, , to display the Natural Language expressions you entered. Note that while Natural Language is displayed, the text of the Condition and Action rows cannot be edited.

**Figure 232: Rulesheet with natural language text**

Cargo.ers				
Conditions	0	1	2	3
a	-	<= 20000	-	> 20000
b	-	-	> 30	<= 30
c	-	-	-	-
d				
Actions				
Post Message(s)				
A		standard	oversize	heavyweight
B				
C				
D				
Overrides			{1, 4}	

3. To revert to original, editable expressions, Click the **Natural Language: Off** menu button, .

---

## The Corticon Studio reporting framework

---

Corticon Studio contains a flexible and extensible framework for generating reports from its files.

Each type of Studio asset uses a built-in XML template that defines the structure of an XML report generated by Studio. Then, a built-in XSLT stylesheet transforms the XML into a regular HTML file viewable with a standard web browser such as Microsoft Internet Explorer or Mozilla Firefox

The *Quick Reference Guide* covers the mechanics of creating reports using the standard templates included with the installation. This chapter describes how to customize reporting templates and formats by taking advantage of the inherent flexibility of XML.

For details, see the following topics:

- [How Corticon creates reports](#)

## How Corticon creates reports

When a user selects **Rulesheet > Report**, Corticon Studio automatically:

- generates a XML file using its built-in XML template
- transforms the XML to HTML using its built-in XSLT stylesheet
- displays the HTML file in a web browser
- copies the XML and HTML files to the JVM's temporary directory. In Windows, by default, this is C:\Users\{user}\Local Settings\Temp. You can change this by adding the following line to `Studio.ini` located in the `[CORTICON_HOME]\Studio` directory

```
-Djava.io.tmpdir=<your new Reports directory>
```

- Use *forward* slashes when writing the path to your new Reports directory, such as C:/Program Files (x86)/Corticon/ Studio/myReports

## Customizing the XSLT stylesheets

Corticon Studio's built-in XSLT stylesheets cannot be viewed or modified. However, you can tell Studio to use an XSLT stylesheet of your own creation if you want to generate custom Studio reports. The files required, including a sample copy of the built-in XSLT stylesheets, are located in `[CORTICON_WORK_DIR]\Samples\Reports\Rulesheet` (or `\Vocabulary`, `\Ruleflow`, `\Ruletest`).

Once you have created your own XSLT stylesheet (or modified the sample provided), copy the entire `[CORTICON_WORK_DIR]\Samples\Reports` directory to the `[CORTICON_HOME]\Studio\eclipse\configuration\com.corticon.brms` (full Corticon Studio) or `[CORTICON_HOME]\Studio\configuration\com.corticon.brms` (Corticon Studio for Analysts).

When you close and re-open Corticon Studio, it will "discover" the new XSLT stylesheets and use them to generate reports.

---

## Troubleshooting Rulesheets and Ruleflows

---

In addition to being a convenient way to test your Rulesheets with real business scenarios, the Corticon Studio Ruletest facility is also the best way to troubleshoot rule, Rulesheet, and Ruleflow operation. Corticon Ruletest are designed to replicate exactly the data handling, translation, and rule execution by Corticon Server when deployed as a Java component or web service in a production environment.

This means that if your rules function correctly when executed in a Corticon Ruletest, you can be confident they will also function correctly when executed by Corticon Server. If they do not, then the trouble is most likely in the way data is sent to Corticon Server – in other words, in the technical integration. This is such a fundamental tenet of rule modeling with Corticon, we'll repeat it again:

*If your rules function correctly when executed in a Corticon Studio, they will also function correctly when executed by Corticon Server. If they do not, then the trouble is most likely your client application's integration/invocation with/of Corticon Server.*

We offer the following methodology to guide your rule troubleshooting and debugging efforts. The basic technique is known generically as "half-splitting" or "binary chopping", in other words, dividing a decision into smaller logical pieces, then setting aside the known-good pieces systematically until the problem is isolated.

This guide is not intended to be an in-depth cookbook for correcting specific problems since, as an expression language, the Corticon Rule Language offers too many syntactical combinations to address each in any detail.

For details, see the following topics:

- [Where did the problem occur?](#)
- [Using Corticon Studio to reproduce the behavior](#)
- [Troubleshooting Corticon Server problems](#)
- [Test yourself - questions – troubleshooting rulesheets and ruleflows](#)

## Where did the problem occur?

Regardless of the environment the error or problem occurred in, we will always first attempt to reproduce the behavior in Studio. If the error occurred while you were building and testing rules in Corticon Studio, then you're already in the right place. If the error occurred while the rules were running on Corticon Server (in a test or production environment), then you will want to obtain a copy of the deployed Ruleflow (.*erf* file) and open it, its constituent Rulesheets (.*ers* files) and its Vocabulary (.*ecore* file) in Studio.

## Using Corticon Studio to reproduce the behavior

It is always helpful to build and save "known-good" Ruletests (.*ert* files) for the Corticon Rulesheets and Ruleflows you intend to deploy. A known-good Ruletest not only verifies your Rulesheet or Ruleflow is producing the expected results for a given scenario, it also enables you to re-test and re-verify these results at any time in future.

If you do not have a known-good Ruletest, you will want to build one now to verify that the Ruleflow, as it exists right now, is producing the expected results. If you have access to the actual data set or scenario that produced the error in the first place, it is especially helpful to use it here now. Run the Ruletest.

## Running a Ruletest in Corticon Studio

When you run a Corticon Ruletest, it might produce error messages in Corticon Studio. Error messages are distinct from **Post** messages you specified in Rulesheet **Rule Statements** to generate info, warning, and violation statements that are posted by normal operation of the rules.

- If you encounter any of the following errors, take the actions described in that section. It may be possible, using these techniques, to work around a problem by identifying the expression syntax that produces it, and trying to express the logic in a different way. The Corticon Rule Language is very flexible and usually allows the same logic to be expressed in many different ways.
- If you do not encounter any of these errors, proceed to the [Analyzing Test Results](#) section.

### The Constraint Violation

**Figure 233: A Constraint Violation in a Ruletest**

Severity	Message
Violation	An unexpected error occurred in Input Data: com.corticon.cdo.ConstraintViolationException: constraint violation setting Cargo.volume to value [-1]

A constraint violation indicates that values in test attributes are not within numeric constraint ranges or not included in enumerated lists that have been set in the Vocabulary's Custom Data Types. In the following example, the constraint is shown, and its violation is marked on the attribute and its entity in the Input column:

Running the test halts at the first constraint violation. The log lists the first constraint exception and its detailed trace. No response is generated.

You can revise the input to have valid values, or choose to relax enforcement of such violations through a setting in the Corticon `brms.properties` file,  
`com.corticon.vocabulary.cdt.relaxEnforcement=true`.

When the option is enabled, a response is generated that includes each of constraint violation warnings. For example:

```
<CorticonResponse xmlns="urn:Corticon"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" returnTransients="true"

decisionServiceName="C__install_dir_work_dir_Studio_workspace_Tutorial_Cargo.ers_null_ALL">

  <WorkDocuments inbytes="3612" returnTransients="true" inputTransients="true"
invokedByTester="true">
    <Cargo manuallycreated="true" datasource="Client" id="Cargo_id_1"
newOrModified="true">
      <weight manuallycreated="true" datasource="Client">0</weight>
      <volume manuallycreated="true" datasource="Client">-1</volume>
      <container manuallycreated="true" datasource="Client"
newOrModified="true">standard</container>
    </Cargo>
  </WorkDocuments>
  <Messages version="0.0">
    <Message postOrder="cc00000001">
      <severity>Warning</severity>
      <text>constraint violation setting Cargo.weight to value [0]</text>
      <entityReference href="Cargo_id_1" />
    </Message>
    <Message postOrder="cc00000002">
      <severity>Warning</severity>
      <text>constraint violation setting Cargo.container to value
[secure]</text>
      <entityReference href="Cargo_id_1" />
    </Message>
    <Message postOrder="cc00000003">
      <severity>Warning</severity>
      <text>constraint violation setting Cargo.volume to value [-1]</text>
      <entityReference href="Cargo_id_1" />
    </Message>
    <Message postOrder="cc00000004">
      <severity>Info</severity>
      <text>[1] Cargo weighing <= 20,000 kilos must be packaged in a standard
container.</text>
      <entityReference href="Cargo_id_1" />
    </Message>
  </Messages>
</CorticonResponse>
```

See [Relaxing enforcement of Custom Data Types](#) on page 39 for details about constraints and the option to relax enforcement.

## The Null Pointer Exception

**Figure 234: A Null Pointer Exception as Shown in a Ruletest**

Severity	Message	Entity
Violation	Rule execution has abnormally terminated due to encountering a java.lang.NullPointerException	

A null pointer exception (NPE) almost always indicates a problem with the rule engine, whether it is being employed by the Corticon Studio or by Corticon Server. If you encounter this error, contact Technical Support, and set aside copies of the Vocabulary, Rulesheet, and Ruletest so we can use them for further troubleshooting.

## The Reactor Exception

**Figure 235: The Reactor Exception Window**

This error is also indicative of a possible rule engine problem, but it may also indicate improper or unnecessarily complex language usage in your rule expressions. The Rule Language's flexibility may permit workarounds to the limitation(s) that produced this message; Progress Corticon Technical Support should be contacted for further assistance. As with the NPE errors, please save copies of the Vocabulary, Rulesheet, and Ruletest for use by Progress Corticon Support staff.

## The Fatal Exception

On very rare occasions, you may experience a full crash of the Corticon Studio application. In these cases, you will see a window like the following:

**Figure 236: The Fatal Error Window**

This type of problem can only be resolved by Corticon. But before contacting Progress Corticon Technical Support, click on the **Advanced >>** button, which will display a window with more information about the cause of the error, as shown below:

**Figure 237: The Fatal Error Details Window**

Click the **Copy** button (as shown) and paste the text into a text file. Send us this text file along with the standard set of Corticon Studio files (Vocabulary, Rulesheet, Ruletest) when you report this problem.

## Analyzing Ruletest results

This section assumes:

- Your Ruletest produced none of the errors listed above, or
- You or Corticon Technical Support identified workarounds that overcame these errors

Does the Rulesheet produce the expected test results? In other words, does the *actual* output match the *expected* output?

- If so, and you were using the same scenario that caused the original problem, then the problem is not with the rules or with Studio, but instead with the data integration or Corticon Server deployment. Proceed to [Troubleshooting Server Problems](#)
- If not, the problem is with the rules themselves. Continue in this section.

## Tracing rule execution

A first step in analyzing results of executing Decision Services is to gain visibility to the rules that fired. With rule tracing, you can see what rules and Rulesheets fired in processing a work document. Rule tracing can be used during development time in the Studio Tester or with deployed Decision Services. The following example uses the Advanced Tutorial's Ruleflow as the test subject. The Ruleflow has three Rulesheets, each with conditional and non-conditional rules.

**Figure 238: Rule messages when metadata is enabled in Studio**

Severity	Message	Entity
Info	[Checks,2] The customer is a Preferred Cardholder	Customer[1]
Info	[coupons,2] \$2 off next purchase when 3 or more Soda/Juice items are purchased in a single visit.	ShoppingCart[1]
Info	[coupons,3] 10% off next gas purchase when total is over \$75.	ShoppingCart[1]
Info	[coupons,B0] \$1.649800 cashBack bonus earned today, new cashBack balance is \$10.889800.	ShoppingCart[1]
Info	[use__cashBack,1] cashback.bonus has been deducted from the total. New total = \$71.600200. Today's savings = \$10.889800.	ShoppingCart[1]

The metadata can be expressed in natural language, such as, for line 1: "In Rulesheet Checks.ers, rule 2 generated this statement", and, for line 4 "In Rulesheet coupons.ers, line B's non-conditional (column 0) action generated this statement."

To enable this function, rule statement metadata, set the `CcServer` property as `com.corticon.reactor.rulestatement.metadata=true`

**Note:** It is recommended that you create or update the standard last-loaded properties file `brms.properties` to list override properties such as this for Corticon Studios and Servers. See the introductory topics in *"Configuring Corticon properties and settings" in the Server Integration and Deployment Guide* for information where to locate this properties file.

**Note:** For Decision Service deployments, set this property where the Deployment Console runs, and then regenerate each ESD file in the Deployment Console. For CDD deployments, set this property on the Server, and then regenerate and compile each Decision Service.

## Identifying the breakpoint

To understand why your rules are producing incorrect results, it's important to know where in the Rulesheet or Ruleflow the rules stop behaving as expected. At some point, the rules stop acting normally and start acting abnormally – they “break”. Once we identify where the rule breaks, the next step is to determine why it breaks.

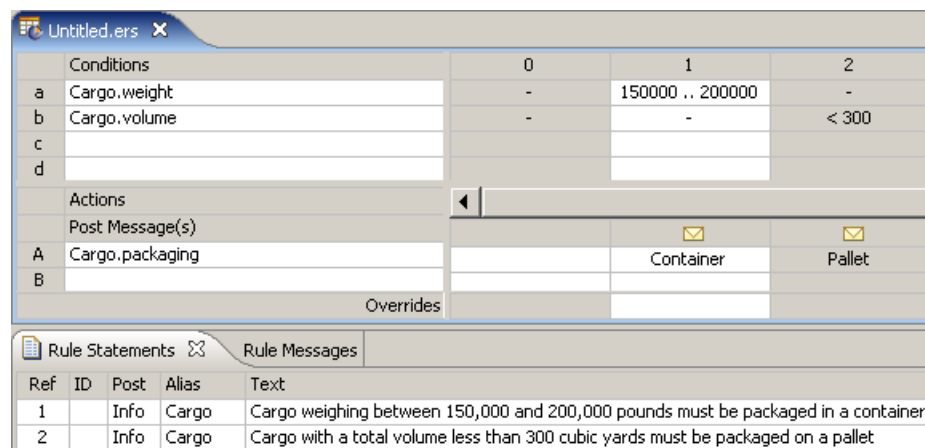

Because of a fundamental Corticon Server behavior, the breakpoint will always be a single rule. If the data available to Corticon Server causes **all** of a rule's Conditions to be satisfied and Corticon Server is able to execute **all** of the rule's Actions, then Corticon Server will fire the rule.

An important corollary to this: if any one of the rule's Actions cannot be executed (for reasons to be discussed later), then none of the Actions will be executed – the rule will not fire. Bottom line: a rule will fire in its entirety or not at all. We call this “all or nothing” behavior.

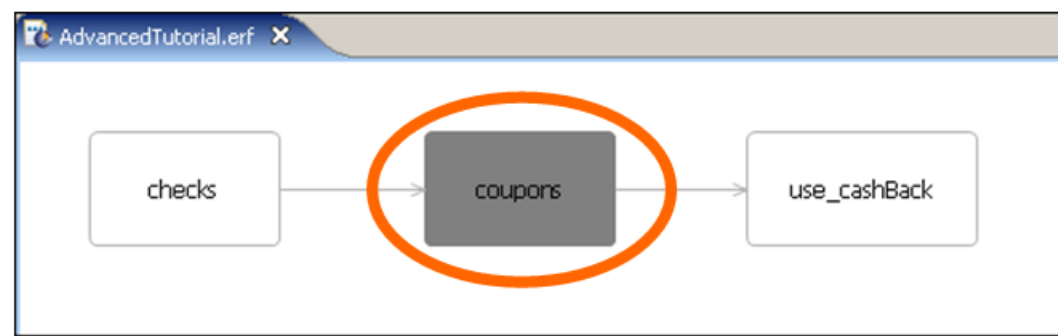

An important tool to help identify the breakpoint is the Ruletest's message box. By choosing values for **Post** and **Alias** columns in the **Rule Messages** window, you can generate a trace or log of the rules that fire during execution. The message box in a Ruletest will display those messages in the order they were generated by Corticon Server. In other words, the order of the messages in the box (top to bottom) corresponds to the order in which the rules were fired by Corticon Server. While messages in the message box can also be sorted by Severity or Entity by clicking on the header of those columns, clicking on the Message column header will always sequence according to the order in which the rules fired. Inserting attribute values into rule statements can also provide good insight into rule operation. But beware; a non-existent entity inserted into a rule statement will prevent the rule from firing, becoming the cause of another failure!

Enabling and disabling individual Condition/Action rows, entire rule columns, Filter rows, and even whole Rulesheets is another powerful way to isolate problems in your ruleset. Right-clicking Condition or Action row headers, column headers, Filter row headers, or Rulesheet boxes in the Ruleflow will display a pop-up menu containing enable/disable options. Disabled rows and columns will be shaded in gray on the Rulesheet, while disabled Rulesheets turn dark gray in the Ruleflow diagram. Be sure to save these changes before running a Ruletest to ensure the changes take effect.

**Figure 239: Rulesheet with Rule Column #2 Disabled.**

**Figure 240: Disabled Rulesheet, Tab Label Circled.**

Disable rows, rule columns, and/or Rulesheets until the strange or unexpected behavior stops.

## At the breakpoint

At the point at which abnormal behavior begins, what results is the breakpoint rule producing?

- No results at all – the breakpoint rule *should* fire (given the data in the Ruletest) but does not. Proceed to the [No Results](#) section.
- Incorrect results – the breakpoint rule *does* fire, but without the expected result. Proceed to the [Incorrect Results](#) section.

## No results

Failure of a rule to produce any results at all indicates the rule is telling the rule engine to do something it can't do. (This assumes, of course, that the rule *should* fire under normal circumstances.) Frequently, this means the engine tries to perform an operation on a term that does not exist or isn't defined at time of rule execution. For example, trying to:

- Increment or decrement an attribute (using the `+=` or `-=` operators, respectively) whose value does not exist (in other words, has a `null` value).
- "Post" a message to an entity that does not exist, either because it was not part of the Ruletest to begin with, or because it was deleted or re-associated by prior rules.
- "Post" a message with an embedded term from the Vocabulary whose value does not exist in the Ruletest, or was deleted by prior rules.
- Create (using the `.new` operator) a collection child element where no parent exists, either because it was not part of the Ruletest to begin with, or because it was deleted or re-associated by prior rules.
- Trying to *forward-chain* -- using the results of one expression as the input to another -- within the same rule. For example, if Action row B in a given rule derives a value that is required in Action row C, then the rule may not fire. Both Actions must be executable independently in order for the rule to fire. If forward-chaining is required in the decision logic, then the chaining steps should be expressed as separate rules.

## No partial rule firing

A Condition/Action rule column should never "partially fire", meaning Action 1 is executed but Action 2 is not. If Action A cannot execute, then Action B will not execute either, even if there is nothing wrong with Action B by itself. An Action containing any one of the problems listed above is sufficient to prevent a rule from firing, even if all other Actions in the rule are valid. Understanding this "all or nothing" execution behavior is very important for troubleshooting.

An exception to this rule is the special Nonconditional rule column 0. Each Action row in column 0 counts as its own separate, independent rule, so Action row A may fire even if Action row B does not.

## Initializing null attributes

Attributes that are used in calculations must have a non-null value to prevent test execution failure. More specifically, attributes used on the right-hand-side of equations (that is, an attribute on the right side of an assignment operator, such as `=` or `+=`) are *initialized* prior to performing calculations. It is not necessary for attributes on the left-hand-side of an equation to be initialized – it is assigned the result of the calculation. For example, when you are calculating `Force=Mass*Acceleration`, you must provide values for Mass and Acceleration--Force is the result of a valid calculation.

Initialization of attributes is often performed in Nonconditional rules, or in rules expressed in Rule Sets or Rulesheets that execute beforehand. That was often because an Attribute that was set to Extended Transient mode could not be added as Input to Ruletests. The limitation has been removed: You can add Extended Transients to the Input column of a Ruletest. Then, as stated, you must provide a value to such attributes in their Input locations in Ruletests to enable valid execution.

## Incorrect results in Studio

Once the breakpoint rule has been isolated, it is often helpful to copy the relevant logic into another Rulesheet for more focused testing. Refer to the *Rule Language Guide* to ensure you have expressed your rules correctly. Be sure to review the usage restrictions for the operator(s) in question.

If, after isolating and verifying the suspicious expression syntax, you are unable to fix the problem, please call Progress Corticon Technical Support. As always, be prepared to send us a) the product version used, and b) the set of Corticon files (.ecore, .ers, .erf, and .ert) that will allow us to reproduce the problem.

## Troubleshooting Corticon Server problems

This section assumes that Corticon Studio problems, including incorrect rule expression, have been ruled out or fixed in previous topics. When the Corticon Server side is involved, the best troubleshooting tool is the set of log files produced during Corticon Server operation.

By default, Corticon Server produces one log that records all the activities of running Decision Services at the specified log level. While higher detail levels produce a more comprehensive basis for analysis, the details of all running Decision Services will also generate detail information into the log. It is a good practice when diagnosing problems to use Corticon Server's ability to generate logs for each specified Decision Service and sublevels so that you can produce detailed logs for just a selected service while other Decision Services continue with less intensive logging.

---

**Note:** For details on setting Decision Service level logging with granularity as fine as Decision Service Major.Minor version by thread, see *"Logging at the Decision Service level" in the Server Integration and Deployment Guide*.

---

The following procedure describes setting a higher log level the Server-level log.

To configure the common log to produce more detail:

1. Stop Corticon Server.
2. Go to the location of your Corticon Server's `CcConfig.jar` file. In the default Tomcat installation (in Windows), this is `[CORTICON_HOME]\Server\Tomcat\webapps\axis\WEB-INF\lib`
3. Open `CcConfig.jar` with a standard archive utility (such as WinZip or 7-Zip), and then locate the text file `CcCommon.properties`.
4. Change the `loglevel` property's value to `INFO`.
5. Save the edited file, and then repackage it into the `CcConfig.jar`
6. Restart Corticon Server, and then rerun the test.

7. Go to the directory containing log files. In the default installation, this is `[CORTICON_WORK_DIR]/logs`. Locate today's log file. Its filename is in `yyyymmdd.log` format.
8. Either delete or rename today's log file. A new log file is created every day, and each Corticon Server transaction adds entries to the day's log. Because daily log files may become quite large, it is useful to start with a fresh log that records only the problematic transaction. The next time Corticon Server processes a transaction, a new log file will be created and entries made in it.

### ***What is Corticon Server's response?***

#### **No response**

In most cases, the failure of Corticon Server to produce a log file means that the invocation/request is not even reaching it! The most common causes of a non-responsive (invocation produces no log file entry) Corticon Server include:

- Incorrect Corticon Server deployment. Review procedures in the *Server Integration & Deployment Guide* to ensure correct deployment.
- Incorrect Corticon Server invocation
  1. Incorrect URL. If using a web services deployment, ensure the SOAP message is addressed correctly, and that no firewalls or port configurations prevent the SOAP message from reaching Corticon Server.
  2. Incorrect API. Review the *Server Integration & Deployment Guide* for complete details on Java APIs available for Corticon Server invocation. A complete *JavaDoc* and sample code set is also provided in the `[CORTICON_HOME]\JavaDoc` directory.
- Even though Corticon Server may not respond to an incorrect invocation, the host server or container (app server, web server, and similar) may respond either at a command line or log level. Check to see if the host server has responded to your invocation.

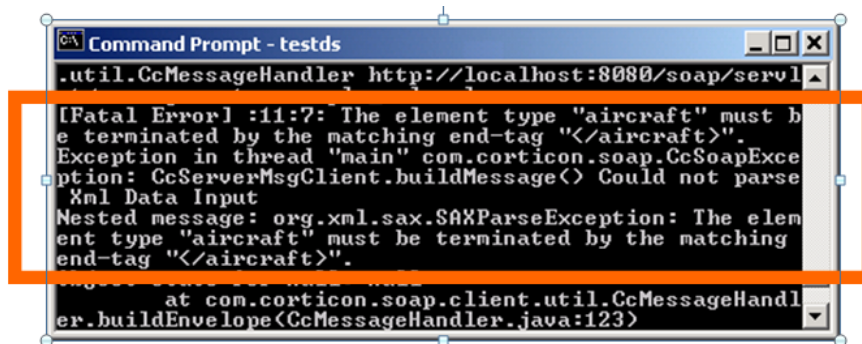

#### **Response containing errors**

The most common causes of erroneous Corticon Server responses include:

- **Incorrect messaging**
  1. Message payload does not conform to service contract. Compare your SOAP message to the service contract produced by the Deployment Console to ensure compliance. Many third-party tools are available that automatically validate an XML document (in this case, the SOAP message) to its schema (in this case, the WSDL service contract). Notice that if Corticon Server cannot even parse the inbound SOAP message, no entry will be made in

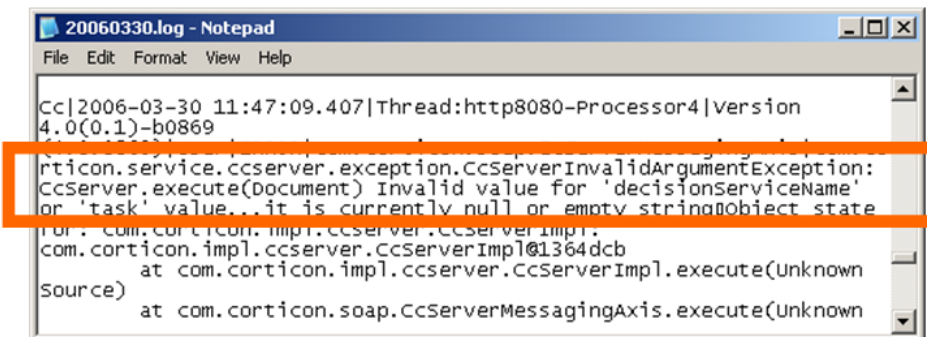

Corticon Server's log. Instead, the error message will be displayed directly in the web server window, as shown:

**Figure 241: Server Window Message Highlighting Incorrect SOAP Request Structure**

2. Incorrect or missing Decision Service Name. Ensure the SOAP message's Decision Service Name attribute matches the name of the Decision Service as it was deployed by either a deployment descriptor file or an API method call, as shown:

**Figure 242: Log Excerpt Highlighting Missing Decision Service Name in SOAP Request**

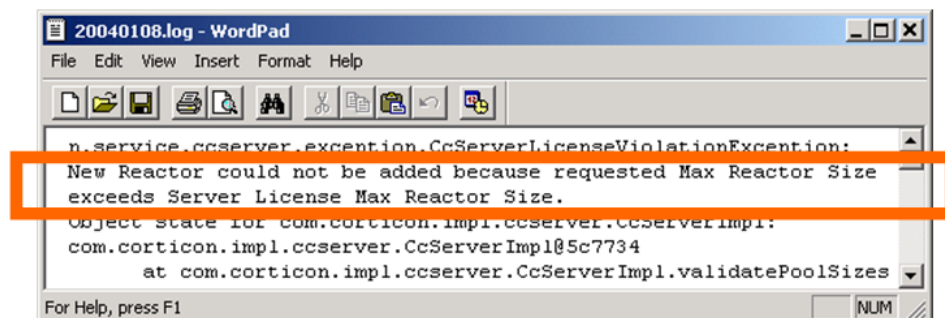

- **Corticon Server licensing problem**

1. License not installed. Your `CcLicense.jar` license file must be located in the same directory as your server installation's `CcServer.jar` file. In the default installation, `CcServer.jar` is located in `[CORTICON_HOME]\Server\Tomcat\webapps\axis\WEB-INF\lib`, so ensure your valid license file is there.
2. If you are using one of the `.war` or `.ear` packages provided in `[CORTICON_WORK_DIR]\Samples`, then be sure that those packages also include valid copies of `CcLicense.jar`.

3. License expired. See your Progress Corticon representative for an updated license file.

**Figure 243: Maintenance Message in Server Window****Figure 244: Log Excerpt Highlighting License Expiration Message**

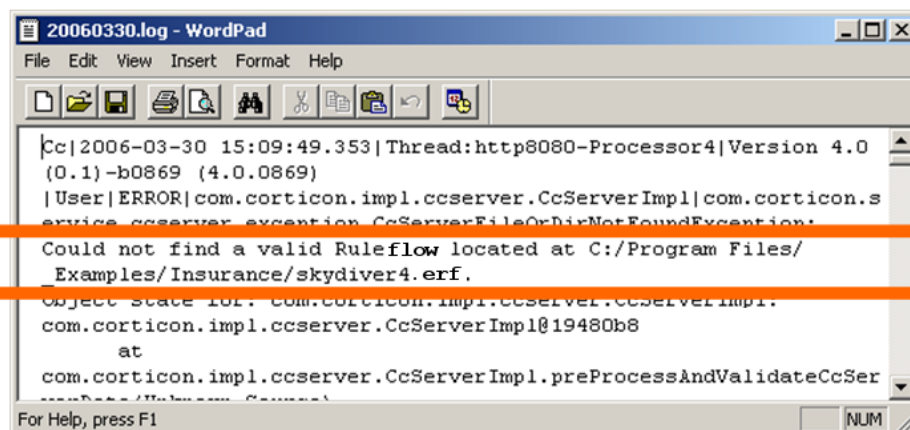

4. License capacity exceeded. License capacity is measured in several ways:
  - Number of unique Decision Services that may run concurrently in Corticon Server. Make sure your license can support the total number of unique .erf files referenced by deployed .cdd files.
  - Number of *copies* of Decision Services the Corticon Server may create to handle transaction volume (known as "Reactors"). Make sure your license can support the max pool size specified in the deployed .cdd files. See figure below.
  - Number of rules allowed for all Decision Services deployed. Make sure your license can support the total number of rules contained in all the deployed .erf files.
  - IP address (or multiple) allowed. Make sure your license URL address matches the address of your Corticon Server.
  - Number of transactions per time period allowed. Make sure your license can support the total number of transactions per time being requested of Corticon Server.

**Figure 245: Log Excerpt Highlighting License Pool Limitation**

- **Deployment Descriptor** (.cdd) file problems

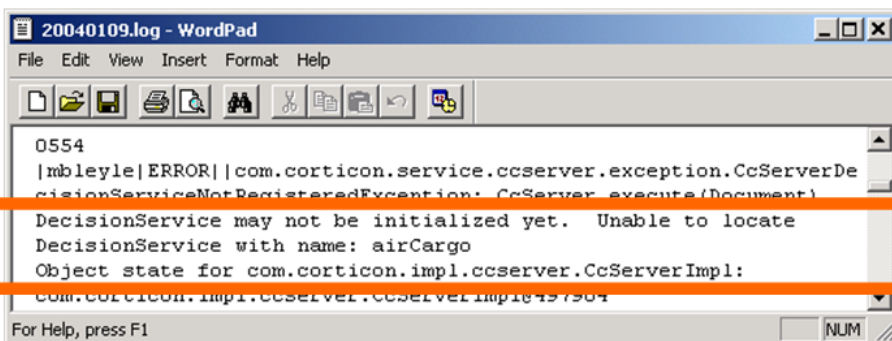

1. Missing .erf file. The .erf file has been moved and is no longer located in the directory referenced by the .cdd file.

**Figure 246: Log Excerpt Highlighting Incorrect .erf Path**

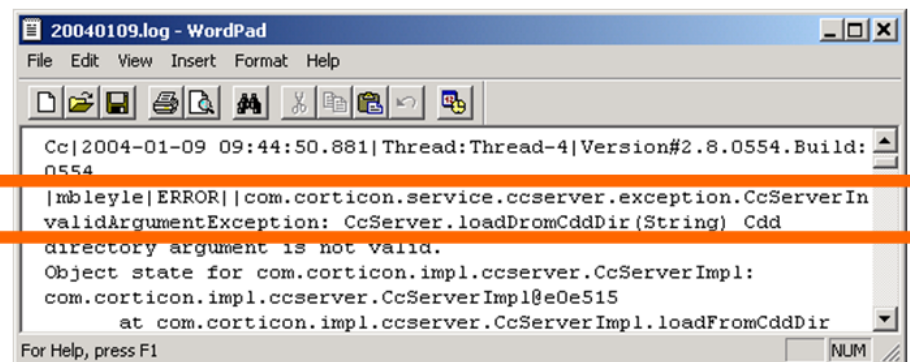

2. Missing .cdd file. The .cdd file is missing from the \cdd directory, or the taskname contained in the SOAP request message does not match any of the tasknames in any of the .cdd files deployed to Corticon Server.

**Figure 247: Log Excerpt Highlighting Unknown Decision Service Name**

3. Missing \cdd directory. The proper location of this directory in your server installation (when installed using default parameters) is [CORTICON\_WORK\_DIR]\cdd

**Figure 248: Log Excerpt Highlighting Missing \cdd Directory**

- **Object translation errors** due to incorrect Vocabulary external name mappings

1. External names mapped incorrectly
2. External data types specified incorrectly
3. ALL entities must be mapped, even those where all attributes are transient.

## Test yourself - questions – troubleshooting rulesheets and ruleflows

---

**Note:** Try this test, and then go to **Answers:** [Troubleshooting rulesheets](#) on page 290 to correct yourself.

---

1. Troubleshooting is based on the principle that Rulesheets behave the same way when tested in Corticon Studio as when executed on \_\_\_\_\_.
2. The first step in troubleshooting a suspected rule problem is to reproduce the behavior in a Corticon Studio \_\_\_\_\_ (test)
3. If the Rulesheet executes correctly in Corticon Studio, then where does the problem most likely occur?
4. Which of the following problems requires you to contact Progress Corticon Support for help?

Fatal Error	Null Pointer Exception	Reactor Error	Expired License
-------------	------------------------	---------------	-----------------

5. The specific rule where execution behavior begins acting abnormally is called the \_\_\_\_\_.
6. True or False. When a rule fires, some of its Actions may execute and some may not.
7. What Corticon Studio tools help you to identify the Rulesheet's breakpoint?
8. A dark gray-colored Rulesheet box within a Ruleflow indicates that the Rulesheet has been \_\_\_\_\_.
9. A disabled rule:
  - a. executes in a Corticon Studio Test but not on the Corticon Server
  - b. executes on the Corticon Studio but not in a Corticon Studio Test
  - c. executes in both Corticon Studio Tests and on the Corticon Server
  - d. executes neither in a Corticon Studio Test nor on the Corticon Server
10. Where is the Corticon Server `loglevel` setting located?
11. To produce a more detailed Corticon Server log file, what `loglevel` setting should be enabled?
12. True or False. The Corticon Server license file needs to be located everywhere the Corticon Server is installed.
13. If you are reporting a possible Corticon Studio bug to Corticon Support, what minimum information is needed to troubleshoot?
14. Which of the following cannot be disabled?

- a. a Condition row
- b. an Action row
- c. a Filter row
- d. a leaf of the Scope tree
- e. a Noncondition row (i.e., an Action row in Column 0)
- f. a rule column
- g. a Rulesheet
- h. a Ruleflow

## Standard boolean constructions

---

For details, see the following topics:

- [AND](#)
- [NAND](#)
- [OR](#)
- [XOR](#)
- [NOR](#)
- [XNOR](#)

### AND

In a decision table, a rule with **AND**'ed Conditions is expressed as a single column, with values for each Condition aligned vertically in that column. For example:

1. If a person is 45 or older and smokes, then classify the person as high risk
---

PolicyApplicantBoolean.ers				
Conditions		0	1	
a	Applicant.age >=45	-	T	
b	Applicant.smoker	-	T	
Actions				
Post Message(s)				
A	Applicant.riskRating		'high'	
Overrides				
Rule Statements				
Rule Messages				
Ref	ID	Post	Alias	Text
1				If an applicant is 45 or older and smokes, then classify the applicant as high risk

In this scenario, each Condition has a set of 2 possible values:

person is 45 or older: {true, false}

person is a smoker: {true, false}

and the outcome may also have two possible values:

person's risk rating: {low, high}

These Conditions and Actions yield the following truth table:

age >= 45	smoker	risk rating
true	true	high
true	false	
false	true	
false	false	

Note that we have only filled in a single value of risk rating, because the business rule above only covers a single scenario: where age >= 45 and smoker = true. A [Completeness Check](#) quickly identifies the remaining 3 scenarios:

PolicyApplicantBoolean.ers						
Conditions		0	1	2	3	4
a	Applicant.age >=45	-	T	T	F	
b	Applicant.smoker	-	T	F	-	
Actions						
Post Message(s)						
A	Applicant.riskRating		'high'			
Overrides						
Rule Statements						
Rule Messages						
Ref	ID	Post	Alias	Text		
1				If an applicant is 45 or older and smokes, then classify the applicant as high risk		

Completing the truth table and the Rulesheet requires the definition of 2 additional business rules:

PolicyApplicantBoolean.ers					
Conditions		0	1	2	3
a	Applicant.age >=45	-	T	T	F
b	Applicant.smoker	-	T	F	-
Actions					
Post Message(s)					
A	Applicant.riskRating		'high'	'low'	'low'
Overrides					

Rule Statements		Rule Messages		
Ref	ID	Post	Alias	Text
1				If an applicant is 45 or older and smokes, then classify the applicant as high risk
2				If an applicant is 45 or older and does NOT smoke, then classify the applicant as low risk
3				If an applicant is NOT 45 or older, then ignore whether or not the applicant smokes and classify the applicant as low risk

and updating the truth table, we recognize the classic **AND** Boolean function.

age >= 45	smoker	risk rating
true	true	high
true	false	low
false	true	low
false	false	low

Once the basic truth table framework has been established in the Rulesheet by the Completeness Checker – in other words, all logical combinations of Conditions have been explicitly entered as separate columns in the Rulesheet – we can alter the outcomes to implement other standard Boolean constructions. For example, the **NAND** construction has the following truth table:

## NAND

age >= 45	smoker	risk rating
true	true	low
true	false	high
false	true	high
false	false	high

Also known as “Not And”, this construction is shown in the following Rulesheet:

PolicyApplicantBooleanNotAnd						
Conditions		0	1	2	3	4
a	Applicant.age >=45	-	T	T	F	F
b	Applicant.smoker	-	T	F	T	F
Actions						
Post Message(s)						
A	Applicant.riskRating		'high'	'low'	'low'	'high'
Overrides						
Rule Statements		Rule Messages				
Ref	ID	Post	Alias	Text		
1				If an applicant is 45 or older and smokes, then classify the applicant as high risk		
2				If an applicant is 45 or older and does NOT smoke, then classify the applicant as low risk		
3				If an applicant is younger than 45 and smokes, then classify the applicant as high risk		
4				If an applicant is younger than 45 and does NOT smoke, then classify the applicant as high risk		

## OR

age >= 45	smoker	risk rating
true	true	high
true	false	high
false	true	high
false	false	low

PolicyApplicantBooleanOr						
Conditions		0	1	2	3	4
a	Applicant.age >=45	-	T	T	F	F
b	Applicant.smoker	-	T	F	T	F
Actions						
Post Message(s)						
A	Applicant.riskRating		'high'	'high'	'high'	'low'
Overrides						
Rule Statements		Rule Messages				
Ref	ID	Post	Alias	Text		
1				If an applicant is 45 or older and smokes, then classify the applicant as high risk		
2				If an applicant is 45 or older and does NOT smoke, then classify the applicant as high risk		
3				If an applicant is younger than 45 and smokes, then classify the applicant as high risk		
4				If an applicant is younger than 45 and does NOT smoke, then classify the applicant as low risk		

## XOR

Using "Exclusive Or" logic, `riskRating` is high whenever the age or smoker test, but not both, is satisfied. This construction is shown in the following Rulesheet:

age >= 45	smoker	risk rating
true	true	low
true	false	high
false	true	high
false	false	low

PolicyApplicantBooleanXOr.ers

Conditions	0	1	2	3	4
a Applicant.age < 45	-	F	T	F	T
b Applicant.smoker	-	F	T	T	F
Actions					
Post Message(s)					
A Applicant.riskRating		'low'	'low'	'high'	'high'
Overrides					

Rule Statements

Rule Messages

Ref	ID	Post	Alias	Text
1				If an applicant is 45 or older AND does NOT smoke, then classify the applicant as low risk
2				If an applicant is younger than 45 AND smokes, then classify the applicant as low risk
3				If an applicant is 45 or older AND smokes, then classify the applicant as high risk
4				If an applicant is younger than 45 AND does NOT smoke, then classify the applicant as high risk

## NOR

Also known as "Not Or", this construction is shown in the following Rulesheet:

age >= 45	smoker	risk rating
true	true	low
true	false	low
false	true	low
false	false	high

PolicyApplicantBooleanNOR						
Conditions		0	1	2	3	4
a	Applicant.age >=45	-	T	T	F	F
b	Applicant.smoker	-	T	F	T	F
Actions						
Post Message(s)						
A	Applicant.riskRating		'low'	'low'	'low'	'high'
Overrides						
Rule Statements		Rule Messages				
Ref	ID	Post	Alias	Text		
1				If an applicant is 45 or older and smokes, then classify the applicant as low risk		
2				If an applicant is younger than 45 AND does NOT, then classify the applicant as low risk		
3				If an applicant is younger than 45 AND smokes, then classify the applicant as low risk		
4				If an applicant is younger than 45 AND does NOT smoke, then classify the applicant as high risk		

## XNOR

Also known as "Exclusive NOR", this construction is shown in the following Rulesheet:

age >= 45	smoker	risk rating
true	true	high
true	false	low
false	true	low
false	false	high

PolicyApplicantBooleanXOR.ers						
Conditions		0	1	2	3	4
a	Applicant.age < 45	-	F	T	F	T
b	Applicant.smoker	-	F	T	T	F
Actions						
Post Message(s)						
A	Applicant.riskRating		'high'	'high'	'low'	'low'
Overrides						
Rule Statements		Rule Messages				
Ref	ID	Post	Alias	Text		
1				If an applicant is 45 or older AND does NOT smoke, then classify the applicant as high risk		
2				If an applicant is younger than 45 AND does smoke, then classify the applicant as high risk		
3				If an applicant 45 or older AND smokes, then classify the applicant as low risk		
4				If an applicant is younger than 45 AND does NOT smoke, then classify the applicant as low risk		

---

## Building a Vocabulary based on Savvion Dataslots

---

Studio provides a Vocabulary wizard that helps you create a vocabulary file (.ecore) based on the dataslots defined in the Savvion Process Template (.spt) file. Existing .spt files can be used as source files for generating a vocabulary file, if they have dataslots defined in them.

For details, see the following topics:

- [Generating the Vocabulary file](#)
- [Dataslot to Vocabulary Mapping](#)

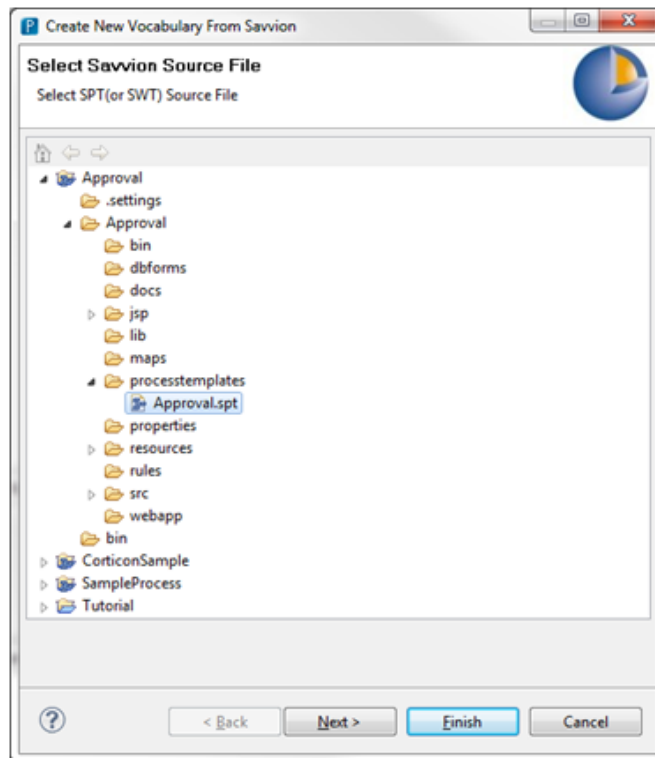

## Generating the Vocabulary file

To generate a Vocabulary file:

1. Select **File > New > Other > Progress Corticon > Rule Vocabulary From Savvion**.

This opens up the **Create New Vocabulary From Savvion** dialog box, as shown in [Selecting the Process Template File](#), which allows you to select the Savvion Process Template file for which you want to create a vocabulary file.

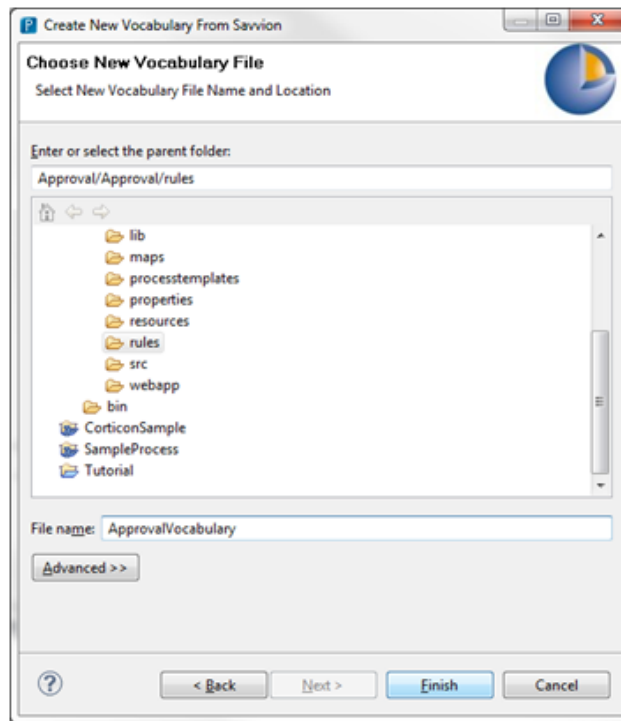

**Figure 249: Selecting the Process Template File**

2. Click **Next**.

This opens up a new window in the **Create New Vocabulary From Savvion** dialog box, as shown in [Location and name for the Vocabulary file](#), which allows you to select the location for the vocabulary file. It also allows you to enter the file name.

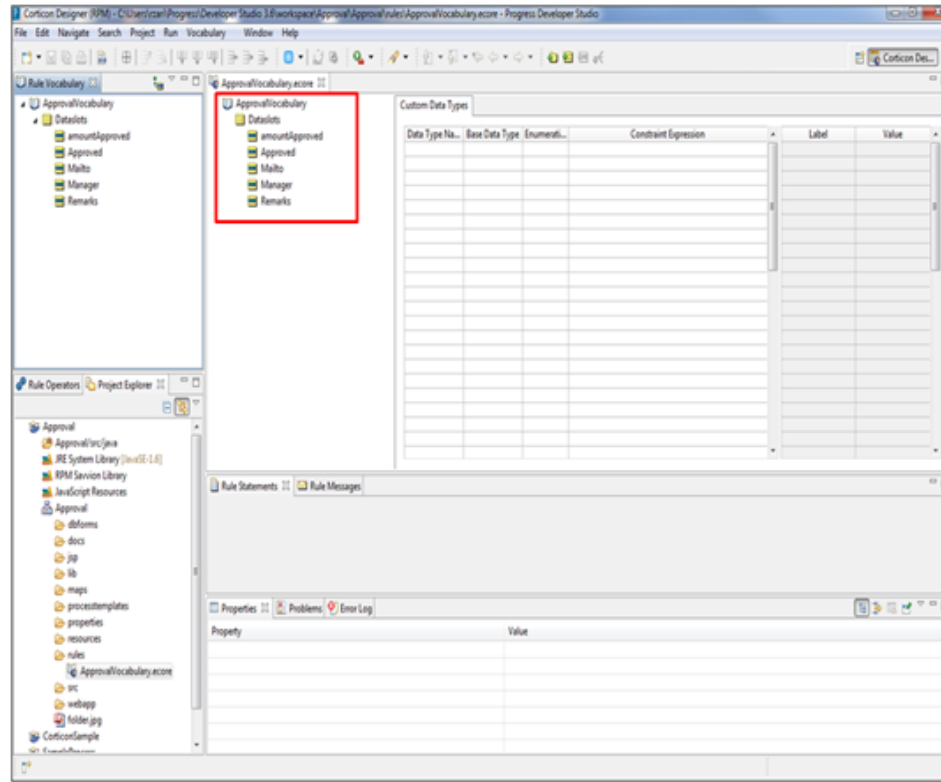

**Figure 250: Location and name for the Vocabulary file**

3. Click **Finish**.

This automatically generates a vocabulary file, as shown in [The Generated Vocabulary File](#), and the dataslots are available as vocabularies for creating business rules.

**Figure 251: The Generated Vocabulary File**

**Note:**

- The 'AllDataSlots' and 'Document' dataslots are ignored while generating the vocabulary file because they are not the supported data types.
- The 'DecisionAuditLog' dataslot is a reserved dataslot and is ignored while generating the vocabulary file.
- A dataslot's Category is not taken into consideration while mapping.

## Dataslot to Vocabulary Mapping

The dataslot to vocabulary mapping is done in the following way:

Savvion	Corticon
Process file (.spt, .swt)	The vocabulary file (.ecore)
Process data slots	An entity with a fixed name as "Dataslots", which contains the dataslots of the process.

Savvion	Corticon
Primitive data slot	A process entity attribute having same name with a correct Savvion-to-Corticon type mapping .
Primitive OE data slot	A process entity attribute having same name with a correct Savvion-to-Corticon type mapping .
System Category	A system entity.
System primitive data slot	The attributes of the system entity with a correct Savvion-to-Corticon type mapping .

The following table displays Savvion-to-Corticon type mapping:

Savvion Data Type	Corticon Data Type
String	String
Number:Integer	Integer
Number:Double	Decimal
Number:Decimal	Decimal
Boolean	Boolean
Date	DateTime
OEBPM:Character	String
OEBPM:DateTimeTZ	DateTime
OEBPM:Decimal	Decimal
OEBPM:Int64	Integer
OEBPM:Integer	Integer
OEBPM:Logical	Boolean

---

## Answers to test yourself questions

---

For details, see the following topics:

- [Building the vocabulary](#)
- [Rule scope & context](#)
- [Rule writing techniques – logical equivalents](#)
- [Collections](#)
- [Rules containing calculations & equations](#)
- [Rule dependency: dependency & inferencing](#)
- [Preconditions & filters](#)
- [Recognizing & modeling parameterized rules](#)
- [Writing rules to access external data](#)
- [Logical analysis & optimization](#)
- [Ruleflow versioning and effective dating](#)
- [Troubleshooting rulesheets](#)

### Building the vocabulary

[Show me this set of test questions.](#)

1. any three of the following:
  - a. provides terms that represent business "things"
  - b. provides terms that are used to hold transient (temporary) values within Corticon Studio
  - c. provides a federated data model that consolidates entities and attributes from various enterprise data resources
  - d. provides a built-in library of literal terms and operators that can be applied to entities and attributes
  - e. defines a schema that supplies the contract for sending data to and from a Corticon Decision Service
2. False. The Vocabulary may include transient terms that are used only in rules and that don't exist in the data model.
3. False. Terms in the data model that are not used by rules do not need to be included in the Vocabulary.
4. False. A Vocabulary may be created before its corresponding object or data model exists.
5. The Vocabulary is an **abstract** model, meaning many of the real complexities of an underlying data model are hidden so that the rule author can focus on only those terms relevant to the rules.
6. The UML model that contains the same types of information as a Vocabulary is called a **Class Diagram**
7. Entities, Attributes, Associations
8. hairColor
9. yellow
10. Attributes
11. Boolean, DateTime, Decimal, Integer, String
12. blue and yellow
13. orange and yellow
14. An Extended Transient Vocabulary term is used when the term is needed to hold a temporary value that is not required to be stored in external data.
15. Associations are **bidirectional** by default
16. cardinality
17. 
18. 
19. Target.source.attribute
20. target

- 22.
23. identify terms, separate terms, assemble and relate terms, diagram vocabulary remove answer from question
24. a
25. operators
26. Rule Language Guide
27. False. Custom Data Types must be based on the 7 base data types. They extend the 7 base data types.
28. b. May match other Custom Data Type Names
29. True
30. value < 10
31. True
32. No
33. 'Airbus'
34. Attribute values are pre-populated in pulldowns based on the enumerated values.
35. Allow you to re-use entities by "bundling" or creating a "sub-set" within the vocabulary. (technically equivalent to packages in Java or namespaces in XML.)
36. True.
37. True.
38. All entities have native attributes, but Bicycle = 100% native, the others have 1 native attribute each and 3 inherited. Entities with inherited attributes = MountainBike, RoadBike, TandemBike
39. cadence, gear, or speed
40. True.

## Rule scope & context

[Show me this set of test questions.](#)

1. 7 root-level entities are present
2. all terms are allowed **except** DVD.actor
3. Movie.supplier
4. a. Movie.oscar  
b. Movie.roles  
c. Actor.roles  
d. DVD.supplier  
e. Movie.dvd.extras  
f. Actor.roles.movie.oscar
5. Actor.roles.movie
6. Since the association between Actor and Role is bidirectional, we can use both Actor.roles and **Roles.actor** in our rules.
7. Movie and Award
8. from Movie to Award: goldenGlobe and oscar. From Award to Movie: two unique rolenames exist for this perspective, too, but are not visible in the Vocabulary diagram.
9. The Award entity could be split into two separate entities, or an attribute could be added to Award to identify the *type* of award.
10. Using roles helps to clarify rule context.
11. unique
12. True
13. all examples shown are Boolean expressions
14. can use Movie if it is the root term, or DVD.movie if DVD is the root term The root term can either be Movie or DVD – no conditions in the rule prevent either one from being the root term
15. can use Movie.dvd if Movie is the root term, or DVD if it is the root term The root term can either be Movie or DVD – no conditions in the rule prevent either one from being the root term
16. False. Both Movie and DVD terms in this example are root terms with no relationship to each other.
17. Once for the Movie satisfying the rule conditions and its *associated* DVD
18. Twice: once for each DVD (i.e. the cross product of the DVDs and the Movie satisfying the rule conditions)
19. a. High  
b. Low  
c. Low for each DVD  
d. Twice: once for each DVD  
e. Four: each of the 2 rules fired 2 times  
f. cross product  
g. no, each rule should only fire once for the DVD *associated* with the Movie  
h. change the Movie and DVD terms to share the same scope, starting either with Movie as the root term (Movie and Movie.dvd) or DVD as the root term (DVD and DVD.movie)

- 20. False. Aliases are only *required* to be used in certain circumstances, but they can be used at any time and provide a good way of simplifying rule expressions.
- 21. Scope is another way of defining a specific **context** or **perspective** in the Vocabulary
- 22. be updated
- 23. False. Each alias must be unique and cannot have the same spelling as any term in the Vocabulary.

## Rule writing techniques – logical equivalents

[Show me this set of test questions.](#)

- 1. Preconditions act as master rules for all other rules in the same Rulesheet that share the same **scope**
- 2. An expression that evaluates to a True or False value is called a **Boolean** expression
- 3. True
- 4. False. The requirement for complete Values sets only applies to Condition rows.
- 5. The special term **other** can be used to complete any Condition row values set.
- 6. not
- 7. {T, F}
- 8. all **except** Entity.boolean=F are equivalent, however some expressions are more clear than others!
- 9. Entity.boolean is probably the best choice since it is the simplest and most straightforward. The other two choices use double negatives which are harder for most people to understand.
- 10. a. OK as is
  - b. if the value range is supposed to contain Integer values, then a does not belong. If the range is supposed to contain String values then 1 and a need to be surrounded by single quotes as in {'1'..'a', other}
  - c. the special word other can't be used as a range endpoint.
  - d. the range contains overlaps between 5 and 10, but this is acceptable in v5.
  - e. the range contains an overlap at 10, but this is acceptable in v5.
  - f. this is an incomplete set and should be {'red', 'green', 'blue', other}
  - g. the range contains overlaps between 3 and 15, but this is acceptable in v5.
- 11. False. The term other may **not** be used in Action row Values sets since Actions can only assign *specific* values.

11. set the navigability of the association between Order and LineItem to Order->lineItem. In other words, make the association one-directional from Order to LineItem.
12. Optional, Convenient
13. A collection alias is not required in this case because no collection operator is being applied to the collection.
14. forAll
15. exists
16.
  - a. aroles ->size > 3 *where aroles is an alias for Actor.roles*
  - b. mdvd ->isEmpty *where mdvd is an alias for Movie.dVD*
  - c. mdextras ->exists(deletedScenes=T) *where mdextras is an alias for Movie.dVD.extras*
  - d. mgglobes ->exists(win=T) *where mgglobes is an alias for Movie.goldenGlobe*
  - e. mroles ->size > 15 *where mroles is an alias for Movie.roles*
  - f. mdvd.quantityAvailable ->sum >= 100 *where mdvd is an alias for Movie.dVD*
  - g. mdvd.quantityAvailable ->sum < 2 *where mdvd is an alias for Movie.dVD*
  - h. mdsuppliers ->size > 1 *where mdsuppliers is an alias for Movie.dVD.supplier*
17. Actor, Distributor, DVDEExtras
18. Actor, Movie
19. The ->forAll operator tests whether **all** elements of a collection satisfy a condition. The ->exists operator tests whether **at least one** element of a collection satisfies a condition.
20. The ->notEmpty operator tests whether a collection is not empty, meaning there is at least one element in the collection. The ->isEmpty operator tests whether a collection is empty, meaning there are no elements in the collection.
21. To ensure that the system knows precisely which collection (or copy) you are referring to in your rules, it's necessary to use a unique alias to refer to each collection.

## Rules containing calculations & equations

[Show me this set of test questions.](#)

1. comparison in Preconditions and Conditions, assignment in Nonconditionals and Actions
2.
  - a. 10
  - b. 13
  - c. 22
  - d. 24
  - e. 0
3. This assignment is not valid since an Integer attribute cannot contain the digits to the right of the decimal point in a Decimal attribute value.
4.
  - a. Integer
  - b. String

- c. Boolean
  - d. Decimal
  - e. Boolean
  - f. Boolean
  - g. Boolean
5. a. valid
- b. invalid
  - c. valid
  - d. valid
  - e. valid
  - f. invalid
  - g. valid
6. The part of Corticon Studio that checks for syntactical problems is called the **Parser**.
7. False. Although the Parser in Corticon Studio is very effective at finding syntactical errors, it is not perfect and can't anticipate all possible combinations of the rule language.
8. This Filter tests if the difference between the current year and the year a movie was released is more than 10 years.
9. This Condition tests if the total quantity of DVDs available divided by the number of DVD versions of a movie is less than or equal to 50,000 or greater than 50,000. This same calculation could be performed by using the ->avg operator by itself.
10. If the average quantity available of a DVD is greater than 50,000 for a movie that is more than 10 years old, then flag the movie with a warning.
11. a. False
- b. False
  - c. True
  - d. True
  - e. True
  - f. False
  - g. False
  - h. True

## Rule dependency: dependency & inferencing

[Show me this set of test questions.](#)

- 1. Inferencing involves only a single pass through rules while looping involves multiple passes.
- 2. A loop that does not end by itself is known as an **infinite** loop.
- 3. A loop that depends logically on itself is known as a single-rule or **trivial** loop.

4. False. The Rulesheet must have looping enabled in order for the loop detector to notice mutual dependencies.
5. False. The Check for Logical Loops tool can only detect and highlight loops, not fix them.
6. No, looping is neither required nor wanted for these rules. Normal inferencing will ensure the correct sequence of execution of these rules.
7. Yes, having this Rulesheet configured to Process All Logical Loops enables an infinite loop between rule 1 and rule 2 for DVDs meeting the conditions for that rule.
8. Rule 1 would change the DVD's price tier value to Medium, and then rule 2 and rule 1 would execute in an infinite loop, incrementing the DVD's quantity available by 25,000 repeatedly until terminating after the maxloop property setting number of iterations.
9. Process all logical loops
10. Process multi-rule loops only
11. A **dependency network** determines the sequence of rule execution and is generated when a *Rulesheet* is **saved**.

## Preconditions & filters

[Show me this set of test questions.](#)

1. True
2. False - precondition behavior is optional
3. True - a filter will only "apply" to other rules that share the same scope. This means that other rules acting on data outside the filter's scope will be unaffected.
4. and'ed
5. False. Preconditions/Filters are not stand-alone rules.
6. c
7. a
8. no
9. True
10. full
11. full filter only
12. precondition AND full filter
13. f and d
14. a
15. Oscars:
  - a. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
  - b. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
  - c. Movie 1; DVD 1; Oscar 2
  - d. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
  - e. Movie 1; DVD 1; Oscars 1, 2

- f. none
- g. none
- h. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
- i. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
- j. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
- k. none
- l. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5
- m. none
- n. Movie 1; DVD 1
- o. Movie 1; DVD 1; Oscars 1, 2, 3, 4, 5

## Recognizing & modeling parameterized rules

[Show me this set of test questions.](#)

1. When several rules use the same set of Conditions and Actions, but different values for each, we say that these rules share a common **pattern**.
2. Another name for the different values in these expressions is **parameter**.
3. False. It is usually easier to model them as Conditions and Actions that use values sets.
4. You may accidentally introduce ambiguities into your rules.
5. **X** customers buy more than **\$Y** of product each year
6. Type of customer: {'Platinum', 'Gold', 'Silver', 'Bronze'} and spend amount: {25000..50000, (50000..75000], (75000..10000], >100000}. Depending on how the rules are modeled, one of these values sets will be part of a Condition and should be completed with the special word **other**.
7. These parameters may be maintained in the values sets of an individual Rulesheet, which is easy to perform, but makes reuse more difficult. They may be maintained as Custom Data Types (Enumerated) in the Vocabulary, which makes reuse easier.

## Writing rules to access external data

[Show me this set of test questions.](#)

1. Rule scope determines which data is processed during rule execution.
2. So a Database-enabled Rulesheet does not inadvertently retrieve all the corresponding data in a database, which could be a lot of data!
3. It is extended to the database
4. True. Only root-level entities need to be extended – all other entities are extended automatically because their scope is reduced enough to not be as concerned about massive amounts of retrieved data.

5. See the tutorial *Using EDC*, and the *Integration and Deployment Guide*.
6. No. In general, the rule modeler does not need to worry about where data is stored.
7. Yes. The exception is when rules are written using root-level terms. If the Rule Set is Database-enabled, then these root-level terms may need to be extended to the database.

## Logical analysis & optimization

[Show me this set of test questions.](#)

1. They have the same Conditions but different Actions.
2. All combinations of possible values from the Conditions' values sets are covered in rules on the Rulesheet.
3. No, not all ambiguous rules are wrong or need to be resolved before deployment. Ambiguities may exist in Rulesheets where there are rules that are completely unrelated to each other. In those cases, it may be appropriate for both rules to fire if the Conditions for both are met.
4. No, not all incompletenesses are wrong or need to be resolved before deployment. Incomplete Rulesheets may be missing combinations of Conditions that cannot or should not occur in real data. In those cases, rules for such combinations may not make sense at all.
5. Conflict Checker – second icon; Compression Tool – fifth icon; Expansion Tool – first icon; Collapse Tool – third icon; Conflict Filter – sixth icon.
6. An ambiguity can be resolved by 1) making the Actions match for both rules, or 2) by setting an override for one of the rules.
7. False. Defining an override does not specify an execution sequence, but rather specifies that the rule with the override will always fire **instead of** the rule being overridden when the Conditions they share are satisfied.
8. False. The Completeness Checker will auto-complete the Condition's value set prior to inserting missing rules. This ensures the Rulesheet, post-application of the Completeness Check, is truly complete.
9. The Completeness Checker will detect Rulesheet incompleteness caused by an incomplete values set because it will automatically complete the value set first before inserting missing columns.
10. Yes. One rule can override multiple other rules by holding the **Ctrl** key to multi-select overrides from the drop-down.
11. No, overrides are not transitive and must be specified directly between all applicable rules.
12. No, rules created by the Completeness Checker may be comprised of combinations of Conditions that cannot or should not occur in real data. In those cases, rules for such combinations may not make sense at all.
13. A dash specifies that the Condition should be ignored for this rule.
14. False. The Expansion Tool merely expands a Rulesheet so that all sub-rules are visible. The results can be reversed by using the Collapse Tool.
15. True. It *may* be reversible using **Undo**, or by manually removing redundant sub-rules after expansion.
16. 64 (4 x 4 x 4)

17. It is not necessary to assign actions for a rule column if that combination of conditions cannot or should not exist in real data. We recommend disabling columns added by the Completeness Check that you determine need no Actions.
18. They may be disabled, deleted, or just left as-is with no Actions (but this last option is not recommended since it will still cause activity which can impact performance).
19. Compression Tool
20. The compression performed by the Completeness Checker is designed to reduce a large set of missing rules into the smallest set of *non-overlapping* columns, while the compression performed by the Compression Tool is designed to reduce the number of rules into the smallest set of general rules (i.e. create columns with the most dashes).
21. Even very large databases may still not contain all possible combinations of data necessary to verify Rulesheet completeness. In short, they may be incomplete themselves.
22. Renumber the rules and potentially ask you to consolidate Rule Statements if duplicate row numbers result from the renumbering.
23. Subsumation occurs when the Compression Tool detects that a more general rule expression includes the logic of a more specific rule expression. In this case, the more specific rule can be removed.

## Ruleflow versioning and effective dating

[Show me this set of test questions.](#)

1. False. Ruleflow Effective and Expiration dates may be assigned singly.
2. False. Ruleflow Effective and Expiration dates may be assigned singly.
3. False. Ruleflow Version numbers are optional.
4. Ruleflow > Properties, or click on the Properties window in Corticon Studio.
5. False. A Ruleflow Version number may only be raised, not lowered.
6. False. Ruleflow Effective and Expiration dates are optional.

## Troubleshooting rulesheets

[Show me this set of test questions.](#)

1. Troubleshooting is based on the principle that Rulesheets behave the same way when tested in Corticon Studio as when executed on **Server**
2. The first step in troubleshooting a suspected rule problem is to reproduce the behavior in a Corticon Studio **Test**.
3. In the integration with Corticon Server.
4. All of them!
5. The specific rule where execution behavior begins acting abnormally is called the **breakpoint**.
6. True. In v5, partial rule firing is allowed.
7. Disabling Rulesheets; Filters, Nonconditions, Conditions, Action rows; or rule columns

8. A dark gray-colored Rulesheet tab indicates that Rulesheet has been **disabled**.
9. d
10. loglevel is located in `CcCommon.properties` inside `CcConfig.jar`.
11. loglevel should be set to `INFO`
12. True.
13. Vocabulary (`.ecore`), Rulesheet (`.ers`), and a Ruletest (`.ert`) and the Ruleflow (`.erf`) if any. We also need to know the Corticon Studio version you are using.
14. d and h
